From the vast extent of this empire, and the great range of its temperature, it is not surprising that the productions of every clime are found, or may be successfully cultivated, in some parts of its wide-spread surface. On the E., the great chain of the Ooral separates by a bold line the northern European from the northern Asiatic botany; and over this vast expanse winter reigns with excessive severity, while the almost tropical temperature of the brief summer ripens the productions of the vegetable kingdom to sudden maturity. This rapid growth is followed by as rapid a decay in autumn.

The forests of Russia are in several respects an important feature of the country: firstly, as a physical characteristic, from their overspreading such enormous tracts of country; secondly, in a commercial point of view, from the timber, tar, pitch, potash, and turpentine which they afford forming important articles of trade; and thirdly, from their supplying fuel in a country only recently found to possess coal. " Estimating the surface of European Russia," says Mr Schnitzler, "at 402,100,552 dessiateens, 156,000,000 of this number are occupied by forests; 178,000,000 by uncultivated land, water, houses, and roads; 61,500,000 by arable, and a little more than 6,000,000 by meadow land. On this general view of the surface, we may compute that one dessiateen of wood occurs to every two, and five-ninths of a dessiateen without it. The forests, indeed, constitute a source of riches which may long continue inexhaustible, and which might be indefinitely increased by strict regulations for their economy and management. Seventy-six millions of dessiateens are still completely covered with pines, firs, and other cone-bearing trees, without counting the oaks, maples, beeches, poplars, and elms, which are by no means rare in the latitudes within the 52d degree, and the birch, which grows in still more northern regions. . . . The governments of Novgorod and Tver, in particular, are studded with forests, and that of Volkonski, which extends to the Valdai Hills, is one of the largest known. In the government of Perm, out of 18,000,000 of dessiateens, 17,000,000 are forest. These immense tracts covered with wood are a great blessing in so inclement a climate, as they form a shelter against the winds from the icy seas. The provinces to the S. have not the same necessity for them, and are so destitute of wood as to occasion the burning of grass and dung for fuel." Forest economy is now being more attended to. The trees furnish the inhabitants with fir-timber of the finest quality for building, household furniture, and utensils. The same trees supply the peasantry in some parts with torches, which they use instead of candles. The brushwood, covering a vast extent of forest land, consists almost entirely of the hazel, dwarf birch, alder, willow, and juniper. In other places the surface of the earth is covered with bilberry, and the cranberry, which latter is extensively exported.

Russia is as yet chiefly an agricultural country. It is so extensive, and in many parts yields such abundant crops of grain, that enough is produced not only for home consumption, but for exportation in considerable quantities. The price of grain varies exceedingly in different governments. St Petersburg, Moscow, Arkhangel, Vologda, and Perm are the only governments that consume more than they raise; all the others produce more than they require. The grains most commonly cultivated are rye and oats. The best wheat is produced in Southern Russia, and in the eastern governments of Kazan, Seembeersk, and Orenburg; where also, along with millet, a little rice is raised. Hemp and flax are very largely cultivated, and yield not only material for the manufactories of the country, but a large

Statistics. surplus for exportation. (For statistics of agricultural productions, &c., see after—"Productive Industry.") Whilst corn and cattle constitute the riches of the central districts the southern abound in productions of a more precious or delicate nature. The peninsula of the Crimea is adapted, both by climate and soil, to all the productions of Italy and Greece; and here, indeed, many of them are indigenous. Government has taken a most lively interest in developing the resources of each portion of the empire; and in consequence of this, the cultivation of the vine, an indigenous plant, the mulberry tree, and the sugar-cane, have been fostered to a considerable extent. The vine cultivation is extending with great success in the south, in the governments of Astrakhan, Kherson, Podolia, the country of the Don Kozzacks, and especially in the Taurida. The mulberry tree has been as carefully attended to as the vine, and the result has been upon the whole favourable. Vast plantations of mulberries have been formed near all the principal towns of the southern districts. Every encouragement is held out to planters by the government. In the Crimea and countries of the Caucasus the rearing of the silk-worm is likewise rapidly advancing. Experiments have also been made to cultivate the sugar-cane and indigo, but they have not succeeded. In Southern Russia, a region whose climate differs little from that of Asia Minor, we find a similar variety of fruits and vegetables. The flora of Russia is very abundant in the south. As Pallas informs us, the country presents the most enchanting aspect. On the mountain-side, in the valley, in the forest, everywhere, the earth is clothed with a profusion of the loveliest flowers and most aromatic herbs, whose delicate odours embalm the atmosphere. Russia further produces hops (not sufficient for home consumption), and tobacco, the *Nicotiana paniculata*, of which the young leaves are generally removed, dried in the shade, and buried beneath hayricks, where they become of a brownish-yellow colour. Of garden vegetables there are the usual varieties found in Europe. Spanish pepper and the mustard-tree are raised on the Samara and Lower Volga; poppy in Kharkoff, where it yields a return of 160-fold; rhubarb, which grows wild in Taurida; rhapontick, which grows wild in the Oorals; and *Polygonum minus*, which in the Oukraine engenders worms that yield a beautiful crimson dye, used as paint by the Kozzack women. Genuine turpentine might be collected to a great extent. Many plants useful for dyeing are produced in a wild state; and for tanning there are several valuable plants. In short, the Crimea presents great facilities for rendering this a lucrative branch of manufacture.

Fruits and flowers.

Garden-stuffs, medicinal plants, and dye-woods.

Animals, cattle, sheep, &c.

The quadrupeds of Russia are numerous. Some appear to be peculiar to the country; but our business is chiefly with the domesticated animals. Cattle of every description are bred in vast numbers in the steppes, and they have increased with the improvement of agriculture. Black cattle and oxen are raised as far N. as the 64th parallel, but especially in Podolia and the Oukraine. Some of the calves of the latter country weight from 480 to 600 lb. Sheep are reared to a great extent. In the Taurida a poor Tartar may have in his possession 1000, and a rich Tartar 50,000. The Merino breed of sheep has been naturalized in Little Russia, in the governments comprised under the name of New Russia, on the S. and E., and in those of the shores of the Baltic Sea. (For statistics, see after—"Productive Industry.") These different regions, so remote from one another, are too dissimilar to enjoy precisely the same advantages; nevertheless, the perseverance and judicious management of the cultivators have been crowned with success. Even in those districts least favoured by nature rapid improvement has been made. At Taganrog the exports have greatly increased; and in Little Russia this branch of commerce is acquiring fresh activity. The wool trade is now also cultivated in Siberia, where a

wool company was established in 1832. In fine, Russia, lately so poor in this species of produce, that even in 1824 her exports did not exceed annually 11,270 cwt., valued at only L.93,500; in 1857 sold 357,977 cwt., the value of which amounted to L.2,069,456. This is of course independently of the demand for home consumption, which has increased to a very large extent. The breed of horses has been considerably improved, by crossing the best native with Arab, English, and Flemish races. Count Orloff was a great benefactor of his country in this respect. So much as L.1560 have been paid for horses from the Oloff breeding-stables. The camel inhabits the warm, saline steppes of the Taurida and Kherson; asses are especially domesticated in the Taurida; and the goat, sheep, swine, and other tamed animals exist in the usual proportions and qualities. Amongst useful insects, there are bees, which yield an abundance of honey and wax for exportation. In the north the reindeer and the elk roam in countless herds; and there are many wild animals, such as the untamed steppe-horse, wild ox, the fox, bear, lynx, and wolf, besides others, the skins or furs of which constitute important items of trade in the northern parts of Russia. Birds of the usual European descriptions are very numerous, including field and water game of various kinds. The falcon is taught to chase even the wolf in the Keergheez-Lands; and in the government of Koorsk the magnificent greyhound of the country is loosed upon the flocks of bustards that are met with there. The seal and walrus haunt the waters of the north; and fish abound in the seas, lakes, and rivers. The fisheries constitute an important branch of productive industry.

Russia consists of the following countries:—Russia proper (originally Novgorod and Moscow); the country of the Kozzacks of the Don, and of the Black Sea; Bessarabia; the khanate of the Crimea; the Caucasus; the kingdoms of Kazan and Astrakhan; Siberia; Daouria and the Amoor region; the kingdom of Poland; the greater part of Lapland; the grand principality of Finland; the archipelagoes of Abo and Aland, with the islands of Dago and Oesel; the Baltic provinces of Courland, Esthonia, and Livonia; and possessions in North America. In administrative respects, Russia is divided into governments and provinces, of which in 1856 there were 65.

	Governments	Provinces.	Kozzack-Lands.
European.....	47	1	1
Caucasian.....	6	0	1
Siberian.....	4	5	0
Total.	57	6	2

The land of the Black Sea Kozzacks belongs to the Caucasus. The population of this empire, as diverse as its component parts, was estimated in 1856 at nearly 71,500,000 souls, including Poland and Finland, thus distributed:—

In Europe.

The European governments and provinces	57,602,185	
The kingdom of Poland	4,696,919	
The Grand Principality of Finland.....	1,632,977	
		63,932,081

In Asia.

The lieutenancy of the Caucasus, with the dependent lands.....	3,179,997	
The Siberian governments and provinces, with the Keergheez-Lands.....	4,120,815	
		7,300,812

In America.

Possessions of the North American Company.....	10,728	
Total population.....		71,243,616

The increase may be computed at 0.88 per cent.; and the population must therefore now, in 1859, amount to 73,387,600 souls. It doubles itself in 114½ years.

Statistics.

Statistics.

Table of the Population and Superficies of the Russian Empire.—Each Government is taken separately, and the Number of Inhabitants is that returned for 1856, in the Tables drawn up by the Central Statistical Committee. The Area is based on the calculations of Academician Koppen, founded on the returns of the Ninth Census.

			Total	63,295,933	..

The central governments are the most populous; and the North American possessions the most thinly inhabited. 9·80 souls go to the English square mile in the whole Russian empire, exclusive of Poland and Finland:—

	Population.
In European Russia	31·08
In the Caucasus	22·49
In Siberia	0·74

And in the whole empire, without the dependent lands

The whole population of the empire was further distributed in 1856 in the following manner:—

	Number of Inhabitants of both Sexes.		
	In Towns.	In Districts.	Total.
In the European governments and provinces	5,203,187	52,398,998	57,602,185
In the lieutenancy of the Caucasus	288,102	2,618,895	2,906,976
In the Siberian governments and provinces	192,710	3,160,105	3,352,815
Total	5,683,999	58,177,998	63,861,997

The proportion betwixt the town and district populations was consequently as follows:—

	To every 100 Inhabitants of the Governments there lived,—	To 1 Inhabitant of the Governments there falls in the	To 1 Inhabitant of the Governments there falls in the
	In Towns.	In Districts.	Districts.
In the European governments and provinces	9·03	90·97	10·07
In the lieutenancy of the Caucasus	9·91	90·09	9·40
In the Siberian governments and provinces	5·75	94·25	16·39
In the whole empire	8·91	91·09	10·23

Numerical Proportion of the Sexes.

	Males	Females.	Total.
In the 49 European governments and provinces	28,331,969	29,270,216	57,602,185
In the 7 Caucasian do.	1,519,220	1,387,777	2,906,997
In the 9 Siberian do.	1,738,314	1,614,501	3,352,815
Total	31,589,503	32,272,494	63,861,997

Hereto add the population of the dependent possessions:—

In the Caucasus, about	291,000
In the Keerghèez hordes of Siberia, about	750,000
In the North American possessions	10,723
Total	1,051,723

Total population

If we further add the number returned by the secretaries of state for Poland and Finland, we have,—

In the 5 governments of Poland	4,696,919
In the 8 governments of Finland	1,632,977
Total	6,329,896

Entire population of Russia, with incorporated and dependent lands in 1856

Movement of the Population in 1856.—Number of Births and Deaths; also increase of Population.

	Born.	Died.	Increase of the Population.

Serfs.

In all European Russia the total amount of the male population in 1857 was 28,613,380 souls, and in this number are included 10,844,902 male serfs. The number of female serfs is supposed to be greater, in consequence of the constant draft entailed by the conscription. They are not taken into count for financial reasons, as they pay no taxes. The serf percentage of the whole population in European Russia is thus 37·90; *i.e.*, out of *one hundred souls* of the entire population, more than one-third, or about *thirty-eight* souls, are in a state of serfage. All these serfs belong to 114,967 proprietors, which number amounts to no more than 0·40 per cent., or two-fifths of the whole male population of European Russia. In the year 1856 so many as 6,596,620 souls,—*i.e.*, 60·82 per cent., or three-fifths of the

Both Sexes.

total number of serfs,—were hypothecated to the crown-banks for debts of their holders, amounting to L.62,186,665. In Asiatic Russia, out of a population of 2,818,948 souls, there were 1844 serfs belonging to 153 proprietors, which gives a serf percentage of 0·06 on the whole population. A serf at present pays to his master a poll-tax (*obrok*) of from L.1, 5s. to L.4 yearly, subject to family considerations too long to enumerate; and to the government a capitation-tax of about 6s. yearly; of which part goes to the national treasury, and part to the communal fund, toward salaries for judges, road-repairing, &c. The government peasants, who are considered as free, pay only from L.1, 2s. to L.1, 8s., or L.1, 11s. yearly, including the capitation-tax. There are no poor-rates, but every proprietor is bound to provide for his destitute serfs. The government does the same. The schools for the crown peasants are as follows:—Under the first and second departments of the crown domains, in the settlements of the crown peasants, there are 2511 schools, with 2803 teachers, and attended by 90,178 boys, and 19,486 girls; of which number 488 were Mohammedan schools, with 511 teachers, and attended by 13,588 boys and 6016 girls.

In the number of crown peasants, it is noteworthy that there are 268,473 who live on crown lands, and possess, besides, land of their own in freehold; and that of the above number only 29,101 live on their own freeholds, without taking the benefit of the crown lands.

The serfs in Russia were not originally attached to the soil, or to the persons of their masters. It was when the Ruricks died out, and a boyar, Boris Godoonoff, ascended the throne, that the nobility got the ascendant, and that the peasants were deprived of the right to remove at will from master to master. By this *ookaz*, dated 21st November 1601, every peasant was thenceforth attached to the soil of that commune in which he might happen to be on St George's Festival; and "Yoorieff Den" has ever since been a day of wail and woe throughout the land. It should therefore be well understood that the people were first enslaved, not by their tsars, but by the nobility, whom they therefore look upon as their despoilers. The tsar is rather looked up to as a father. This circumstance explains many matters in Russia. By *ookaz* of the emperor, promulgated on the 5th December 1857, the serfs are to be finally liberated within twelve years after settling the terms to be resolved on between them and the proprietors. The intervening period is considered needful to prepare the serfs for the coming change in their position. In every government a committee has been appointed, consisting of two deputies from the nobility of every district, and to this number are adjoined two deputies as members for the crown. Their labours, with the opinions thereon of the provincial governors, and of the minister of the interior, are subsequently revised by the Central Committee of Serf Emancipation sitting at St Petersburg. It was originally the emperor's intention to convoke in the capital an assembly of proprietors; but whether from the probability of stormy discussions or dislike of anything resembling a representative system, a commission has been appointed, and now sits at St Petersburg, to collect opinions and to decide on the final plan. The chief difficulty lies in conciliating the conflicting interests of the proprietors and peasants. The former would willingly enough part with their serfs, but they wish to retain the whole of their lands, or to receive for them full compensation, according to their own estimate. The emperor, again, has decreed that the peasants shall be allowed 4 dessiateens (about 11 English acres) of land and a cottage in freehold, and this they are allowed to pay for during the twelve years intervening betwixt the settling of the rules and their final emancipation. The sum proposed is moderate enough (L.16); but this is the real point at issue: The rich landholders, 3917 in number, are on

Statistics.

Statistics.

the whole not so much against the measure, because aware that, although they lose the last remnant of their feudal rights, the ultimate gain to their descendants, through rent-income and tillage of their estates by free labourers, is certain. The Russian noble, however, looks more to the present than to the future, and has little public spirit, as in England. It is the minor landholders, 111,050 in number, who are most dissatisfied, and for the following reasons:—In some trading and manufacturing governments, the central in particular, land is very dear, and the proprietors have positively not enough disposable soil for portioning off to their peasants the number of dessiateens required, which it has been proposed shall be reduced to 3. Land in those parts, and about St Petersburg, Taganrog, &c., is fully worth L.16 the dessiateen; in other parts only from L.4 to L.8. Some proprietors, besides, who possess forty peasants, have but 60 dessiateens of land in all; so that to allow them only 3 dessiateens, the proprietors must purchase 60 dessiateens additional to make up the 120 dessiateens at least required. Other proprietors possess 1000 dessiateens, with 400 peasants, and they would be deprived of the whole of their lands, besides having to purchase 200 or 600 dessiateens more were they to give the 3 or 4 dessiateens demanded. Some, again, who are perfectly landless, possess as many as fifty house-serfs. What are they to do? In Little Russia, and some other parts, land is very cheap, and there the proprietors would be at an advantage; for they could easily afford to pay the peasants as free labourers. As Russia comprises different climates, soils, and peoples, the difficulty of settling rules in all their details becomes manifest; it is therefore believed that the country will be divided into *zones*. It is also noteworthy that in Siberia there are very few serfs, and they are mostly attached to the government foundries; so that this portion of the empire can be first freed. In order to develop national industry, Peter I. bestowed serfs both on nobles and merchants, in various manufacturing governments, on condition that these men should revert to the crown, in case the manufactories were closed. These people, who were called possession-serfs, are landless, and now amount to about 40,000. The Emperor Nicholas did all he could to diminish their number, which was 100,000. The position of this class was dreadful, and they were positively slaves. Fears are entertained that the peasants will desert their villages, and when no longer attached to the glebe, will turn more to trade than follow agricultural pursuits. When roused, these peasants are an intractable class. The great point is, that the matter is too far advanced to be withdrawn; and come of it what may, the reign of Alexander II., who is pledged to the measure, will be immortalized by a glorious act, that can best be contrasted with the barbarity of the one that reduced the peasants, 258 years ago, to their present condition.

Government.

The government of Russia is an absolute hereditary monarchy. The emperor, or White Tsar of his people, rules of divine right, and acknowledges no fixed law but his own will. Round his diadem is wound the pontifical tiara, and he bears the following titles:—By the grace of God, Emperor and Autocrat of all the Russias, of Moscow, Keeyeff, Vladeimir, Novgorod; Tsar of Kazan, Tsar of Astrakhan, Tsar of Poland, Tsar of Siberia, Tsar of the Tauric Chersonesus; Lord of Pleskoff, and Grand Duke of Smolensk, Lithuania, Volhynia, Podolia, and Finland; Duke of Esthonia, Livonia, Courland, and Semigallia; of Samogitia, Bielostock, Karelia, Tver, Yugoria, Perm, Viatka, Bulgaria, and other lands; Lord and Grand Duke of Lower Novgorod, Tcherneegoff, Riazan, Poldtsk, Rostoff, Yaroslaff, Bieloosersk, Oodor, Obdor, Condia, Veetebesk, Mstislaff; Dominator of all the Land of the North; Lord of Iberia, Cartalinia, Georgia, Cabardia, and of the province of Armenia: Hereditary Prince and Sovereign of the

Princes of Circassia and other mountain princes; Successor of Norway; Duke of Schleswig-Holstein, Stormarn, Dithmarsen, and Oldenburg, &c. The dynasty of his house is that of Romanoff the senior, and of Holstein-Gottorp the junior branch. The title of Tsar was first taken 1462–1505 by John III., the breaker of the Tartar yoke, the putter-down of the independent princes, and the conqueror of Novgorod, who married Sophia, niece of the last Greek emperor, Constantine Palæologus. It was he who in consequence quartered the Byzantine arms, the two-headed eagle, with his own of St George the Conqueror, although the tutelar patron of the country is St Nicholas. The Roman and Greek emperors being *Cæsars*, and Cæsar having been pronounced by the old Romans *Tsaysar*, by the Greeks *Kaisar* (*Kaïrap*), it is evident how from *Kaïsar*, by the ellipsis of a syllable, came *Tsar*, written by the ignorant *Czar*, which gives no idea of the sound, as it is Polish for *Char*. Previously to John III. the title of Tsar was unknown, and the Russian sovereigns were always called Grand Princes, which is the title of the emperor's own children; the other members of the imperial house are styled Imperial Highnesses. Princes, Counts, and Barons are the only titles of nobility; the latter being but seldom bestowed. Formerly the sole title was *boyar*, equivalent to feudal lord. These titles descend to all the children equally, and there is no right of primogeniture; although majorats, or entailed estates, have been created in favour of some families. The orders of knighthood are 7 in number. The highest is the purely military order of St George, with four degrees. The others are both military and civil: St Andrew the First-Called, 1 degree; Vladeimir, 4 degrees; St Alexander Neffski, 1 degree; the White Eagle, 1 degree; St Anne, 4 degrees; St Stanislaus, 3 degrees. There are military decorations, such as occasional medals of honour, and gold swords for courage. When any of the above orders are given to military men, *swords* are added to the insignia. For soldiers there is a particular cross of St George, also with 4 degrees, corresponding to the Victoria medal; and further a medal of St Anne, 1 degree. The officials, including teachers in the government service, are all classed as of certain *echins* or ranks, of which there are nominally 14, but really only 12; two having fallen into desuetude. These ranks rise in degree as follows:—14th, or lowest class, college registrar; 13th, does not exist; 12th, government secretary; 11th, does not exist; 10th, college secretary; 9th, titular councillor; 8th, college assessor; 7th, court councillor; 6th, college councillor; 5th, state councillor; 4th, actual state councillor; 3^d, privy councillor; 2^d, actual privy councillor; 1st, the chancellor of the empire. The rank of personal nobility is part of the privilege conferred by the lowest degree, upwards to that of actual state councillor, which confers the privilege of hereditary nobility. The highest department of the government is the council of the empire, established in 1810 to render the laws less changeable, and their application more correct. The other main objects are the revision and sanction of the budget. The number of members is not limited, but it generally amounts to 35 or 36. The council is divided into 5 departments:—1. Legislation; 2. War. 3. Church and civil affairs. 4. Internal political economy, or the administration of the public revenue. 5. The affairs of Poland. The emperor himself is the real president; but the council has further a permanent presiding member, selected by the emperor for life. Each department has its own president and state secretary; and the whole together have a common grand secretary of state, who is the principal director of the chancery, and the organ through whom the council makes known its decisions to the monarch. On receiving the emperor's confirmation of the council's decisions, this grand secretary communicates them

Statistics.

Statistics. to the respective authorities upon whom their execution devolves. Neither this secretary of the council, nor the council itself, receives from private persons any petitions, which must be presented to the Emperor's special state secretary for the receipt of petitions, who, after perusal, forwards them to the respective ministers. Without the monarch's sanction the decisions of the council are valueless. The directing senate is divided into 10 departments: 5 in Petersburg, 3 in Moscow, and 2 in Warsaw. It is the supreme civil and criminal tribunal of the empire, a guardian of the law, and a watcher over the inferior tribunals. The minister of justice is the chief *ober-procuror*, procurator or attorney-general of the whole senate; but every department of the senate has its own crown-attorney, dependent on the *ober-procuror*, or minister of justice. No laws can be promulgated without the senate, which prescribes their execution to all ministers and tribunals by separate edicts, or *oohâzes*, printed in the Senate gazette. The holy directing synod has for its object the management of ecclesiastical affairs. The ministries of state, whose members officiate in their several departments independently of each other, form the first instance of administration. Important affairs, purely administrative, are presented by every minister to the committee of ministers, and their collective opinion is then confirmed by the emperor. Each committee has its own state secretary, who bears to it the commands of the sovereign, and communicates them to the individual chiefs of the administration throughout the empire. The presiding member of the council of the empire is also the president of the committee of ministers. The ministries are as follows:—1. Foreign affairs and state archives; 2. War (artillery, engineering, inspection, audit, commissariat, victualling, and the medical department); 3. Marine and the colonies; 4. The Interior (police, municipal revenue and expenditure, interior administration, foreign religions, and medicine); 5. Public instruction; 6. Finances and trade (revenues and expenditure, trade, manufactures, treasury of the empire, customs, and mines); 7. The crown domains (crown-lands, peasants, and their management); 8. Justice; 9. The general direction of land and water communications; 10. Financial control; 11. Ecclesiastical affairs (Russian church); 12. The imperial household and appanages; 13. The post-office. The emperor's chancery, divided into four sections; one of which, the third, comprising the secret police, is another high organ of government; and there is, further, a special minister or state secretary for Poland, and a secretary of state for Finland. The governors and other authorities in the provinces receive their commands through the ministers and their departments. Every government has a civil governor, who is often also military governor.

Ministry of justice. The senate is the third instance, or supreme court of judicature. The nomination to places resting solely with the crown, and all presidents being removable at will, it follows that the courts are nothing but an organ of judicature, entirely at the command of the government; the nobility-assessors not being eligible *of right*, but nominated at the sovereign's will. In the middle courts of second instance, however, the nobility have a privilege of admission, being elected by their own order, and in some cases with merchants for assessors. These courts of second in-

Statistics. stance, which revise the law proceedings of the first instance courts, are the *palâta grazhdânskago soodâ* or civil court, the criminal court, the executive police, the court of conscience, and the commercial court; the last with no deputies from the nobility, but with merchant-assessors only. To the lowest or first instance belong the district court, which investigates, in legal form, all law matters appertaining to it; the *zêmskoy-sood*, or county police court, which is its executive; the nobility tutelage court, all with representatives from the nobility, merchants, burghers, and peasants; the *nadrôrnoy-sood*, or aulic court; the orphan's court; the town magistracies and town-halls, with no representatives from the nobility, but solely from the merchants, burghers, and peasants. There are judges only in the conscience and district courts. Finland and Poland have their independent codes and judicature. The torture is abolished, as are also the knout and slitting of the nostrils. Some criminals are *stamped*, but not branded. The corporal punishment inflicted is the *plet*, or cat-o'-nine-tails; and sometimes, when a criminal is exceptionally punished by military law, running the gauntlet. The nobility, clergy, and merchants are exempted from this punishment. Criminals are further sent to work in the mines of Siberia.¹ The secondary degree is simple banishment to the settlements in Siberia; and the third, infliction of the rod, imprisonment, confinement in penitentiaries and reformatories, public reprimands in court, sometimes entered on the official's commission, and fines.²

All proceedings are carried on in writing, which is the great evil of the system, leading to venality, delay, gorging of the prisons, and vexations innumerable. The administration of justice is indeed the department most requiring reform; for of no country can it be more truly said that there is one law for the poor and another for the rich. But this may be looked upon as a remnant of the old bad order of things which is now being rapidly amended.

The first book of laws was the *Rôsskâia Prâvda*, or Russian jurisprudence, issued by Yaroslaff in 1020, and continued in the thirteenth century. John III. next commenced a book of laws in 1497; and this was again revised by John IV. in 1550. In 1664 the Tsar Alexay Mikhailovitch issued his *Olozhânie*, or general book of laws; and this code formed the foundation of the later jurisprudence, supplemented by *oohâzes*, or edicts, of the successive sovereigns; the number of statutes, up to the time of Alexander I., amounting to 30,920. Many attempts were made regularly to codify the whole; and Peter I., in particular, appointed in 1700 a commission for this purpose. Elizabeth, Catherine, and Alexander I. followed up his plan; but it was Nicholas I. who, after a previous outlay of about L.900,000, partially succeeded in the purpose. Up to 1859, 15 tomes, containing 21 sections, have been published; but the work, although still continued in the second section of the emperor's chancery, is far from concluded, contains numerous errors, and by no means does away with the special edicts of the sovereign, which can at any time upset the written law. The school of jurisprudence was instituted by Nicholas, with a view of bettering matters, by forming legists, and appointing from among them and the law-students of the universities, crown-officials for the senate and law-courts, incorruptible, well-mannered,

¹ No atrocities equalling those of Norfolk or Cayenne are enacted in Siberia, where all the condemned are under the special supervision of the secret police. The town prisons, however, and even the police-stations, are sinks of horror; the condition of prisoners on trial being scarcely better than that of the condemned themselves.

² In 1856 there were (exclusive of Finland and Poland) 283,229 criminal, civil, and police cases; of these, 57,130 were convicted, 53,000 pardoned by manifests, 99,656 acquitted, 1574 sentenced to labour in the mines, 157 sentenced to the settlements in Transcaucasus, 3839 to Siberia. Among the above were 1124 cases of murder, 280 arson, 73 highway robbery, 6049 theft and robbery, 743 burglary, 101 false coining, 126 offences against religion. In Poland many crimes are committed, in Finland few, in Courland but one case occurred. In 1856 acts and obligations to the amount of L.31,353,758 for the sale and transfer of property were registered in the government courts, excepting those of Poland and Finland. In 1849, in 46 governments and 1 province of European Russia there were 1089 cases of murder, 1512 of suicide, 30 infanticide, 3114 child exposure, 804 personal insult, 194 unlawful gratification of the passions, and 690 horse stealing. There were, further, 27,694 vagrants, and 1183 vagrant and thief harbourers.

Statistics. and likely to exercise a beneficial influence on their confraternity. But "a little leaven leaveneth the whole lump;" and no radical good can result until a total sweep is made of the whole corruption, and trial by jury, with public pleading and a free press, introduced—not a licentious, but a public press, for exposing evil, and for giving a voice to the public wants. Trial by jury *did* once exist in the remoter ages of Russian history. The present monarch, Alexander II., who has begun so well, might do still better, would he but extend his admirable reforms to this vital object. When so many princes of the imperial house are appointed to public functions, it is to be hoped that the energies of some will be directed to the sword of justice as well as to the sword of war.

Religion.

The established religion of Russia is the Greco-Russian, nationally called the Orthodox Catholic Faith, and is professed by 49,099,717 souls. This church separated from the Roman in 1054, and from the Byzantine patriarchate in 1587. It has now its own independent synod, but it maintains, with the four patriarchates of Constantinople, Jerusalem, Antioch, and Alexandria, the intimate relations of a sister-church, possessing over them, as well as over the whole Slavonic race, a moral supremacy, which, though not despotic like that of the Roman Church, appears likely one day to rival that of the Pope over the Latins. It further maintains at Jerusalem a mission, with a bishop at its head. This religion was introduced into Russia by the Grand Princess Olga and the Grand Prince Vlodeimir in A.D. 955 and 988. Previously to the year 955, Christianity counted in Russia only a few followers at Keeyeff; but the general introduction into Russia of Christianity is reckoned from the year 988. Under Yaroslaff (1019–1054) Russia had her own metropolitan, but until that time the upper hierarchy came from Greece. In 1589 a patriarch was nominated head of the national religious establishment; but under Peter the Great the emperor was declared its spiritual head, the synod taking the place of the patriarchate. With it was vested the management of ecclesiastical affairs. An *ober-procurator* is its secular chief. The synod consists of permanent and temporal assessors, all selected from among the highest ecclesiastical dignitaries. It is generally composed of three metropolitans, several archbishops of the black, and, further, two assessors of the white clergy, the senior priests of the guards, and of the army and fleet. It never consists of less than three bishops. The ecclesiastical hierarchy, recruited mostly from its own ranks and the lower classes, although the upper also occasionally supply members, is divided into two orders,—the black or monastic, and the white or secular clergy. The following is a return of numbers of the black clergy:—4 metropolitans, of St Petersburg, Moscow, Keeyeff, and Lithuania, and 1 exarch of Grusia; 26 archbishops or archiereis; 39 bishops, also styled archiereis; 176 archimandrites or abbots, and 84 hegoumens or priors; 5612 monks; 2339 nuns; 5849 lay brothers and novices; 7091 lay sisters and novices. The black clergy has Basilus the Great for its tutelar saint, and it is entirely provided for by

the state. White clergy: 1400 protobiereis or arch-priests; 35,593 popes or priests; 12,804 deacons; and 63,358 sub-deacons, readers, sacristans, and low ecclesiastical servants. The secular clergy receive from L.16 to L.40 yearly salary from the state, with some income in fees and in kind, which altogether places them, as a body, above positive want, but no more. When a clergyman gets too old for service, his successor, should he be his son-in-law, is bound to maintain him. When he dies, a place is first found for his son, and his daughter is married off if possible to the successor. A retiring-fund has been instituted, to afford pensions, but it is as yet too trifling for mention. The fees are prescribed by usage, but the priest can be compelled to perform his functions without remuneration. There are 4 first, 19 second, and 27 third class eparchies or bishoprics; in Grusia, 10. Further, 463 monasteries, of which 44 of the first, 85 of the second, and 160 of the third class; the chief or laurel monasteries are the Keeyeff-Grotto, the Trinity-Sergius, the Alexander-Neffski, and the Potchàieffski. There are 129 nunneries and 36,697 churches, of which 145 are for the *Starover*, or Assimilated faith. Spiritual education is provided for by 4 ecclesiastical academies, at St Petersburg, Moscow, Keeyeff, and Kazàn, with 73 professors and 336 students; each with but 1 faculty for theology, although the Hebrew, the ancient and modern Greek, the Latin, and now even the English, German, and French languages are taught, besides mathematics *in extenso*, and the natural sciences in part. Further, 48 seminaries, with 708 teachers and 13,864 scholars; 183 clerical district schools, with 1054 teachers and 36,359 scholars; and 18 clerical parish schools, with 32 teachers and 1401 scholars: total, 253 schools, with 1867 teachers and 51,960 scholars. These church-schools were once the light of the land. Several schools have been founded for clergymen's daughters, but their number is not returned. The national church property cannot be valued, but its capital is stated at L.1,700,000 sterling, and its annual income suffices to defray all the church expenditure, besides leaving a large surplus, which is credited to the church account. It is chiefly derived from the candle-money collected for the wax tapers burned. The amount of free gifts derived from the church-boxes amply suffices to defray the building and repairing of churches. Each government has its archbishop or bishop, excepting the governments of Petersburg, Moscow, Keeyeff, and Vilna, in each of which there is a metropolitan in lieu of an archbishop; and under these metropolitans, archbishops, and bishops are placed all ecclesiastics and schools, excepting those of the war ministry, which has its own senior priests, standing under the synod and the war minister. The archbishop of every government is the president of the government consistory,—a spiritual college, consisting of five to seven members, according to the extent of the bishopric. It is composed of several archimandrites, protobiereis, and some of the worthiest clergymen. For punishment, monks are removed from a higher to a lower class monastery; the secular clergy are sent for a time to monasteries; and for more serious offences are either degraded by one degree, or are deprived of the *riassa*, their every-day upper vestment, their hair being cut off before final dismissal from the clerical function. Grave crimes come under the cognisance of the criminal law of the country; but the clergy possess a right of having deputies to see that they are treated fairly, and they are not sent to prison without the knowledge of the consistory or synod, where the sentence meets with approval or disapproval. The following distinctions exist for protopopes and popes:—Epigonations,¹ pàlitzas,² skull-caps, calottes, the synodal and cabinet *naperstnoy krest*, or

Statistics.

¹ *Epigonation*, a sacerdotal decoration of embroidered stuff, in the shape of a parallelogram, worn on the right hip, below the upper and above the under *reza* or sacerdotal vestment. It denotes the spiritual sword.

² *Pàlitzas*, a similar distinction, but now ranking higher than the epigonation. It is shorter, square, and richly embroidered.

Statistics. breast-slung cross,¹ and the orders of St Anne, 2d and 3d, and of St Vlodeemir, 3d and 4th classes. The same distinctions, excepting the skull-caps and calottes, are given also to the black clergy, from the hieromonach to the archimandrite inclusively; archihiereis and proto-presbyters receive the orders of St Anne, 1st; St Vlodeemir, 1st and 2d classes; of St Alexander Neffski; and of St Andrew the First-Called. All the black clergy indiscriminately wear beads.

Church. The Greco-Russian Church guards vigilantly against the introduction of any doctrine open to the slightest suspicion of heresy, and has its own censorship and journals. It is also very observant of hierarchical subordination. Generally, however, the Russian clergy, although jealous of their dignity, have not the spiritual pride or priestcraft of the Roman Catholic order, attributable no doubt in part to the kindly national character, and in part to the humanizing influence of marriage, which prevents the overwhelming concentration of all the human passions into one single channel. The Greco-Russian Church is mostly antagonistic to the Roman Catholic, and differs from it in the following essential particulars:—1. In not recognising the primacy of the Pope. 2. In denying that the Holy Ghost proceeds from the Son (*filioque*). 3. In rejecting a purgatory, predestination (except in the omniscience of the Deity), indulgences, dispensations, and works of supererogation, although admitting the intercession of saints by prayer. 4. It holds the necessity of complete submersion of the whole body at baptism, unless in urgent cases, when even lay-men and women may perform it; but they must immerse the infant with the baptismal words, "In the name of the Father, Son, and Holy Ghost," if the infant can bear the immersion; if not, then sprinkling or ablution is used. Should the priest arrive in time, he reads the supplementary prayers, and performs the mystery of anointing with chrism. 5. Whilst admitting the doctrine of transubstantiation in regard to the eucharist, it affirms that the holy bread (*προσφορα*) must be leavened; the wine and water being placed in the chalice; and it is only at the prayer of transubstantiation that part of the *agnus* is placed in the chalice. The element of wine with water, is alone administered to children up to the age of seven, for fear of the elements being ejected or falling to the ground. 6. Another important distinction, is that marriage is obligatory on the secular clergy, although monogamy is a strict tenet of the church. A priest may continue to serve after his wife dies. 7. No instrumental music is allowed, but vocal music forms a most attractive portion of the service. This church rejects all massive images of the Saviour or saints as idolatrous; but pictures, mosaics, bas-reliefs, and, in short, all that is represented on a flat surface, is not held a violation of the law which says, "Thou shalt not make unto thee any graven image!" Broadly stated, and besides some of the preceding tenets, the Greco-Russian religion differs from the Anglican in so far as the latter church approaches to the Lutheran. The general harmony, however, with the Anglican is greater than with any other church; and several attempts have been made, but not successfully, to unite them, particularly in 1723. Addresses still pass at intervals between the two churches; and independently of the Irvingites, the ritual of Hatherly's new community at Liverpool so strongly resembles the Greek service that it has attracted the notice of the Russian synod. There are

four great fasts:—1. Lent, or the great fast, between the carnival and Easter, of seven weeks' duration, and of which the first and last are the most rigidly observed, being more specially devoted to repentance, confession, and preparing for the sacrament; 2. The Petroff, or Peter's fast, before St Peter's day in June of two to five weeks' duration, accordingly as Easter Sunday falls; 3. The Oospenski, or Conception fast, called by the people the Gospòzinki, from the 1st to 15th August. 4. The Philippoff, or St Philip's fast, of six weeks before Christmas. The first fast or Lent is the most rigidly observed. Besides the above, the Wednesday and Friday of every week are fast days, and the common people scrupulously keep them all. Catechising and preaching are practised,—the latter frequently, the former at set intervals. Confirmation is not practised, the chrism used at baptism being held to comprise a mystery, rendering that ceremony supererogatory. The church festivals and saints' days, kept with eastern splendour, are numerous, and consequently form drawbacks to the business of life, although they greatly relieve the labouring classes. The venerative feeling of the people is profound, and they are zealous church-goers, early and late, being due observers besides of all the outward forms of religion, in which the essence is sometimes absorbed. There is, however, much genuine piety to be met with; pilgrimages to monasteries are frequent among all classes; donations, free gifts, offerings, and alms, being liberally bestowed by both rich and poor. There are no entrance-fees, no distinctions for great and little, no pews, no reserved places in Russian churches: the congregation stand: all are equal before God. The Sabbath is not much observed, except as a church-going day. The shops are shut during the hours of worship, but all public places of amusement are afterwards thrown open; visits are made, and business is but little affected by obedience to this salutary ordinance of the Supreme Lawgiver. The church service is performed in the ancient church Slavonic, and the lower classes cannot therefore completely follow it, except as a thing they take for granted, although they comprehend its general signification. The Bible, however, is now being translated into the vernacular Russ. The congregation fervently join in the choral parts, the responses, and the ejaculations. This portion of the service, and the great pomp investing the whole system of worship, together with the procession of banners, pictured saints, and relics, have no doubt been the great means of originally impressing on a rude people the holy awe they entertain for tsar and church; which two, with them, are identical. Church service usually consists of the *vòzglass*, or call to worship; singing of psalms or hymns; the *Ektenia*,² a series of prayers, mostly intoned, for the welfare of the church and her chiefs, for the peace and union of the Christian churches, and for every separate member of the imperial family; the reading of the epistles and evangel; choral and part singing of unexampled harmony; a sermon, always in the common language, explaining the evangel read; prayers, preparing for the communion, and during which the priest prepares himself; the consecration of the elements, and the administration of the sacrament, which the clergyman takes every time, and the congregation at will; then, thanksgiving for the sacrament, and parting benediction; the chanting and incense-burning throughout being frequent. Asperging with holy water is also used.³ The Old Testament is read only during evening

¹ *Napèrstnoy krest*, a gold cross slung over the breast, a mark of distinction common to all the black clergy. The imperial family often give, besides, for distinguished services, so-called *brilliant crosses* (diamond). The other crosses for proficiency in the learned degrees are 2 in number: one, a small square gold cross for the degree of *Magister Scientium*; and the other a more elongated, light-blue, enamelled one, for the degree of Doctor of Divinity. The last reward for a member of the white clergy is a mitre.

² The *Ektenia*: there are several forms of prayer so called. Some portions of this service resemble that of the Irvingites.

³ A foreigner is mostly struck by the constant signing of the cross, the repetition of the *Gòspodi Bòmdelooi*, or "Lord be merciful!" the genuflexions, and the semi or entire prostrations.

Statistics. service, which is intended to prepare for the morning or principal service, and it therefore has a prophetic tendency, the psalms and hymns being all appropriate. The morning service represents the fulfilment of these prophecies. Service much of the same kind is often performed—sometimes exorcisms too—at private houses, on special occasions; and the remembrance-service, or *Poménki*, forty days after a person's death, is a pious custom; as is that of the yearly visitation of family graves, although this often degenerates into revelling. It is another laudable custom of the Russians to remove their hats, in the streets, before *all* funerals that pass. Every Russian is obliged to take the sacrament at least once a year. The calendar in use is the Julian or Greek, which is twelve days behind the Gregorian or Latin. The antagonism of the two churches is perhaps the chief objection to a reform in this respect. The superstitious belief of the common people in good and bad spirits, in house-spectres, forest and water demons, is fast dying out, although too much credence is still given to omens and witchcraft. All decent creeds are liberally tolerated,—a beautiful contrast to Roman Catholic usage; and no civil disabilities attach to those who profess another faith, except to the most hateful of the sectarians. The chief attributes of pre-eminence assigned to itself by the Russian Church are the ringing of the larger church-bells—the smaller ones being allowed to the foreign denominations,—and, further, the *public* processions. The Roman Catholics are permitted to walk in state round the outside of their churches when walled in, or within them when not. The host must be carried in coaches. Funerals may be publicly followed by the clergy of all persuasions. Collisions with the populace are thus prudently avoided, whilst perfect toleration is granted. In towns and places where the Roman Catholic faith is predominant, greater public display is permitted. There exists, too, a species of church police, in the form of visitation, at times, of foreign churches by a deputed person. The confine where toleration touches on persecution is in the ordinance, that the children of a foreigner, man or woman, married to a Russian, must, unless specially exempted, be brought up in the national religion. Apostasy to any other faith is strictly prohibited; but Mussulmen and Jews, on the contrary, who go over to the Russian Church, are allowed many immunities,—the latter, a consideration in money! The empress, too, and foreign princesses marrying into the imperial family, must likewise embrace the national religion, but they are not re-baptized, being only anointed with the holy chrism. None but Jews, Mohammedans, and those baptized in one person of the Trinity are re-baptized.

Sectarians.

Since the first introduction into Russia of Christianity, many schisms have taken place, such as the Adrianites and the Self-Mutilators; but the chief separations were:—(1.) In 1649, when a considerable number of Greco-Russians went over to the *Unia*, which was formed

by orthodox believers abandoning the ritual of the national church, and accepting the dogmas of the Roman Catholic faith. The Uniats, 2,000,000 in number, were again forcibly taken into the bosom of the mother church in 1839. (2.) Under the Tsar Alexay Mikhailovitch (1645 to 1676), when the amendment of the church-books occasioned a new separation. Many who believed not in the right correction of the church books of worship, which had become full of errors, formed a community holding to the ancient order of things, and they were called *Stàro-Obriàd-tsi* or *Starovèri* (Old Ritualists or Old Believers), because opposed to all innovations, even in non-spiritual matters. Latterly, some of them have consented to accept priests from among the orthodox hierarchy, on condition of their performing church-service according to the ancient ritual. This section is called the Assimilated Church, and it counts 145 places of worship. Their church-service is very coarse and unimpressive. Those sectarians who accept no such clergy are called the *Bezpopòfstchina*, or Popeless. There are at least 40 different sects, officially stated at about 2,000,000 in number; but the well-informed calculate them as amounting to nearly 8,000,000; and they all conceal their profession as much as possible. The most respectable are the *Staro-Obriàdsti*. The *Dook-hobòrti*, or Soul-Strugglers, and the *Molokhàne* (so called from the locality they inhabit), are schismatics, living, as do the Mennonites, mostly in the south of Russia, and their tenets have much in common with those of the Protestant dissenters, particularly of the Anabaptists. The other sectarians dwell in the remoter governments and in Siberia. Many of their tenets are horrible; the *Skoptsee*, or Self-Mutilators, in particular, who are met with even in St Petersburg, and include some Germans and Fins; but they are rigidly put down, and must eventually finish by becoming absorbed into the national church. Many converts are annually made both from them and other religions,—Mohammedans, Jews, Buddhists, Lamaites, and pagans; the Russian Church prudently confining its charity to its own home-circle of heathen; but there are no sufficient data for specifying the number christianized. This was partly the reason why the Foreign Bible Society-branch, together with free masonry in Russia, was put down by Alexander in 1824. Another reason was jealousy of Protestant interference with the Russian translation of the Bible, which is that of the Septuagint. The Evangelical Church counts many adherents, called *Hernhuters*—United Moravian Brethren,—living mostly in the German colonies on the banks of the Volga, in the town of Sarepta, in Southern Russia, and about Tiflis. The Jews abound mostly in Poland and in the semi-Polish governments. The Karaim Jews, a peculiar sect, dwell in the Crimea.

The Armenio-Gregorian church in Russia has six epar- Armenio-
chies, of which five are under archbishops, and one is ruled Gregorian
by a supreme patriarch. Church.

The present patriarch, Matheos, is the 141st supreme patriarch of the Haikan people since the time of St Gregory, the Enlightener. He has his throne at Etchmiadzin, in Armenia. Church affairs are administered, under him,

Statistics. by a synod consisting of four archbishops or bishops, and four archimandrites. These members are chosen by the patriarchs, and confirmed by the emperor, who likewise sanctions the nomination of the eparchial archbishops. The synod is further assisted by several consistories and spiritual directories. This church is wholly supported by voluntary contributions, the government adding only a sum of about L.1150 yearly for some particular expenses. The Lazareff Institute of Oriental Languages, at Moscow, provides for the education of twenty youths, who are afterwards either ordained as priests, or appointed

as teachers in the seminaries, or to situations in the synod, consistories, and spiritual directories. The Armenio-Gregorian Church considers itself the most ancient in Christendom. It differs from the Greek—with which, however, it has much similarity—in the doctrine of Jesus Christ's humanity; the Armenio-Gregorians maintaining that his two natures, of divinity and humanity, are blended into one; the Greeks, on the contrary, that they are distinct. The Armenio-Gregorian supreme patriarch, or Katholikos, styles himself in consequence *Αυτοκεφαλῇ*, or *independent head*.

* In this number are included 40 parish churches of the Armenian Catholics, and 4 chapels; 54 white parish clergy, and 14,345 parishioners of both sexes.

† Of the total number of these monasteries (72), 49 are on the government civil list, and 23 on the supernumerary list, which implies that they are doomed ultimately to suppression, as has been already the case with many.

Mode of support.

The Roman Catholic clergy are supported from the income of their immovable property and funded capital, which accrued to the government when they were deprived of them in 1841. The reason assigned was, that they were thus only placed on a footing similar to that of the Russian clergy, who are paid by the government, likewise out of the church income. All expenses relating to the church, and amounting to L.110,000, are defrayed by the government out of the above income, the state treasury adding only, of its own, L.6000. Every eparchy has its seminary, and there is one ecclesiastical academy at St Petersburg. There are three tribunals: the eparchial direction, the spiritual college, and the ministry of the interior. This college consists of assessors chosen by every eparchy, and is presided over by the metropolitan. A government procuror, or superior crown-attorney, always attends. This church has its chief seat in Poland and the neighbouring governments. It has two metropolitans: one of Warsaw, for Poland; and one of Mohileff, for the whole empire of Russia. He is the primate, and resides mostly at St Petersburg, which is the seat of the chief ecclesiastical academy.

Lutheran Church.

The consistorial sessions, formed of deputies, take place twice a year, and a government procuror assists at them. As a means of learning the wants of the Lutheran Church, a general synod, consisting of members and deputies of the consistories, is sometimes convened at the pleasure of government. Many evangelical Lutheran churches have large funds, amply sufficient for defraying all their expenses; others, again, receive assistance from government, to the amount of L.9000. All these churches have the undisturbed management of their property. Theological faculties for this confession exist at the universities of Dorpat and Helsingfors. The Bible Society at St Petersburg had distributed 13,000 copies of the Book among members only of the Reformed Church, and had 30,000 more remaining. Its fund amounted to nearly L.2000.

The Reformed denomination counts in all 31 churches and chapels, with 26 officiating clergy. All matters relating to this church, excepting those of the Reformed denomination in the governments of Vilna, Kovno, Grodno, Minsk, and Mohileff, are regulated in separate Reformed church-sessions, held at the Lutheran consistories. The Vilna Evangelico-Reformed synod takes cognisance of all church affairs relating to these last-mentioned governments. There is, also, a spiritual college for this church at Vilna. Of Hebrews, Mohammedans and Pagans, there are as follows:—

Hebrews ¹	1,322,936
Synagogues	345
Rabbis, readers, and teachers	4,935
Mohammedans	1,948,817
Mosques, called metchëds	4,718
Muftis, mullahs, and teachers	7,924
Pagans ²	374,574
Places of worship	490
Priests	4,778

The philanthropic institutions of Russia are mostly under Charitable institutions

¹ We believe this number to be more correct than that given in Koppen's returns of the foreign races. It is a year later.

² In this number of pagans are included,—Lamartes, 190,390; Places of worship, 386; Priests, 4,410.

Statistics. the direction of the Philanthropic Society, composed of various classes, and particularly of merchants. Its chief curator is the metropolitan of St Petersburg. Under this society are many establishments for widows, orphans, the deaf and dumb, cripples, &c. There is also a committee of prison inspection. Besides these, and the alms-houses maintained by the towns, there are numerous establishments supported by the government; such as the foundling hospitals, and the Widows' Home at the Smolna convent. Several more are supported by private charity; as the Demidoff Institution, for orphan girls, and Zoddoff's Asylum, for minor orphans. There were also, in 1851, 75 infant asylums in the whole empire, attended by 7980 children of both sexes.

Education. *Public Instruction.*—Education was introduced into Russia conjointly with Christianity in the tenth century. The first school for boys was founded by the Grand Prince Vlodeemir, Russia's Alfred, about 988; and the first school for girls, under Yaroslaff, 1019 to 1054, by his sister Anne. Public schools were afterwards founded in different parts of Russia during the eleventh century, yet little had been done when the great Peter first flung his mighty intellect into the work before him, and by his rough but useful lessons forced civilization upon his unwilling subjects. This sovereign was indisputably as much the primary teacher of his people as the founder of Russia's present greatness. He began by making education compulsory on the nobility and officials, and each succeeding sovereign after him did more or less in furtherance of his views. The sole honourable record, indeed, of Elizabeth Petrovna's reign is the founding, at Shoovàloff's suggestion, of the Moscow university in 1755, and two years later of the Academy of Fine Arts at St Petersburg, afterwards completed by Catherine II. It was Elizabeth who first showed the first leaning towards Gallic ideas. Catherine II. zealously continued Peter's labour, and was properly the founder of the national schools. Her action is mostly evidenced by the marked introduction, in moral culture, manners, and dress, of an exclusively French system, which continued down to the time of Nicholas. Russia still owes much to Catherine, both in point of learning and refinement of manners; but it is a question whether her system has not been in other respects hurtful by diminishing the national self-respect, and perhaps by corrupting the national morals. Alexander I. greatly contributed to the advancement of learning. He founded the universities of Dorpat, Kharkoff, Kazàn, and St Petersburg, as also the Alexander Lyceum, aidently carrying out the work of reform, much on Catherine's plan, with steady perseverance and great success. His system was chiefly marked by the introduction of a soldier-like discipline in the training of youth. This system was yet more rigidly carried out by Nicholas, to whom still belongs the credit of having been the first to re-Russianize his empire. With this view, he gave a more national direction to the course of studies pursued, by making the Russian language, literature, history, geography, statistics, and knowledge of Russia the chief objects of study. He further prohibited the young gentry from being educated abroad, except by special permission, and even laid restraints on their stay in foreign countries, in order to counteract their inoculation of too liberal ideas. He also made it imperative to obtain his sanction for staying abroad, inflicted passport duties so heavy as to be equivalent to a prohibition from travelling, and sharpened the action of a severe censorship. He still vigorously carried out the work of improving the national education, and, like all his predecessors, considerably increased the number of the learned establishments. This sovereign was vastly superior to any of his predecessors after Peter. His personal gifts, mental and physical, were of the highest order; and few men in his position have possessed so much mastery of the mind over the body.

The accession of the present emperor Alexander II. has been marked by an abatement of his father's restrictions, by a comparative liberty of the press, and, strangely enough, by a happy revulsion in favour of English principles, but without any exaggeration of the sentiment. Already the healthful impulse given in particular to literature surpasses expectation, and promises the happiest results, although in so vast an empire education has of course not yet had time to permeate the masses. The Russian system of education is on the whole too much intended for the eye; too hollow; too superficial; embraces too many objects at once; and does not sufficiently provide for the education of the body. The education of females is the one most requiring reform. Girls of all classes are superficially taught all that they least want to know; whilst the real objects for which woman was created are precisely those mostly left out of view. In the female government establishments an undue luxury prevails, that totally unfits the poor girls for the rude families into whose bosoms they return; and worst of all, their long stay in those semi-conventual establishments damps in them the faculty of love, by severing them from the bonds of family affection. As regards the general *direction* given to learning, it was mostly the scholastico-ecclesiastical spirit that prevailed up to the time of the minister Oovarov, in Nicholas's reign. The system followed in the universities and gymnasia was bad to a degree, having besides the old seminaristic tendency. Oovarov abolished this, and gave to learning a more German or philologo-philosophical direction, in which it now continues, although Nicholas interrupted it awhile by stopping in 1848 the teaching of many branches of philosophy in the universities, retaining only the lectures on logic and psychology, and confiding them to priests, who still occupy these chairs.

The fine arts came into Russia with Sophia, the Greek spouse of John Vassilievitch III. The learned establishments of Russia, religious, military, naval, civil, and special, are severally placed under particular chiefs at the head of these different departments,—Poland and Finland being separately administered,—and are mostly divided into three classes, which take rank according to the degree of distinction that attaches to them, regard being had to the importance of the schools, and to the social position of the scholars. These classes confer on the pupils various advantages, which are held out as inducements for parents to send their children to them for education, it having been found both impossible and needless to carry out the system of compulsory education first enforced by Peter. The academies of sciences and of fine arts, the liberal, charitable, and many special institutions, are under the immediate protection of the imperial family, who further provide for the instruction of their servants' children, as do also several of the separate ministries. By this special superintendence for each branch of education, the object in view is no doubt best attained; but the fault lies in over-government, and in nothing being left to the generous action of public spirit, which is thus destitute of a high moral tone. Teachers in public schools are very properly subjected to examinations as to their competency, but when once this is certified, they partake of the advantages bestowed on the schools in the shape of pay,—which once was liberal, but is not so now,—a gradually rising rank, and subsequently a pension for their old age. Domestic tutors, private teachers, and governesses, are all alike subjected to tests, varying in proportion to the degree they may wish to take, and are thus all equally under the control of the government. Female teachers in the numerous government establishments for young ladies, have advantages corresponding to those of the men. Generally speaking, the social standing of a teacher is, as it ought to be, highly respectable. Not to detail the minor establishments existing under the different

Statistics.

Statistics. ministries, a minute return of which would be of little interest, we shall hereafter give the most important tables when we touch the several heads to which they respectively relate. The following summary will meanwhile answer all needful purposes:—*Æsthetics*, and their affiliated branches, are fostered by an Academy of Fine Arts,—the noblest in Europe,—with its splendid sculpture and picture galleries, and its collection of engravings; the Hermitage, with its countless treasures of sculptures, paintings, and coins; the National and the Roomiantsoff museums; the museum of sculpture in the Taurida Palace; the permanent exhibition of works of art near the Exchange; four porcelain, glass, bronze, and tapestry manufactories; four theatres, including a national and an Italian opera, with a ballet, and where French and German pieces are also performed; one summer theatre, and one court-angers' school,—all at St Petersburg, or near it. A marked feature of the time is the introduction of parks and public squares; some of the bridges, too, in the empire, are of unparalleled magnificence; and generally the improvement in architecture is striking to the dull eye. In architecture, it is the Indian, the ancient Russian, the Russo-Byzantine, the renaissance, and mixed styles that mostly prevail. Moscow has but little to boast of in point of art, unless in the quaint architecture of its Kreml and its countless churches. It possesses a branch-school of the Academy of Fine Arts, and, further, Yablonoff's cabinet of art-curiosities, two theatres, and one theatre-school. Near that city are the picture-galleries of Mr Narishkin, Count Strogonoff, Count Bezborodko, and Prince Yoosoooff. Science is provided for by more numerous establishments: the Academy of Sciences, with its cabinets of natural curiosities and oriental coins, and its costly library; the public library, with 802,717 volumes, 28,536 manuscripts, and 63,503 engravings, independently of the libraries of the universities and ecclesiastical academies; the magnificent astronomical observatory at Poolkova; numerous other observatories at Moscow, Kazan, Nicholaiëff, Dorpat, Riga, Mitau, and other places; the physical observatory at St Petersburg; the cabinets of natural curiosities at Moscow, Vilna, Dorpat, Riga, and Mitau; the scientific collection and models of marine apparatus in the Naval College of St Petersburg; Loder's anatomical museum at Moscow; the museum of South Russian antiquities at Odessa and at Kertch; the Geographical and Imperial Mineralogical societies; the botanical garden; the Free Economical and Horticultural societies; the Society for Mutual Instruction; another for the encouragement of artists,—all at St Petersburg; the Society of Friends of Russian Literature, for Russian history and antiquities; the Medico-Physical Society, for the discussion of the natural sciences, and of pharmaceutical knowledge; the Agricultural and Antiquarian societies: the Literary and Lettish societies; one for rural economy; the Livonian societies of Public Instruction and of Agriculture at Riga; the Courland Society for Literature and the Fine Arts at Mitau; the Literary societies of Kalooga and Zitomir; the Philotechnic and Scientific associations of Kharkoff; the societies of Friends of the Russian Language at Yaroslaff; of Friends of the National Literature and of the Sciences at Kazan; and the Physiological Society at Abo; one of which might have been advantageously replaced by a society for the prevention of cruelty to animals. A society for the acclimation of animals has been recently formed at Moscow, and Mr Lamanski has projected one for the diffusion of useful knowledge.

Among the special institutes, the most noteworthy are the learned section for the oriental languages, under the minister of foreign affairs, instituted to qualify young diplomatists for their vocations; and the Lazareff Institute for the oriental languages at Moscow.

Statistics.

By a decree of the emperor, promulgated in January 1859, the upper pedagogical institute, as it now exists, will be suppressed, and replaced by special courses of pedagogy. Similar pedagogical courses are to be established in all university-towns. The other educational establishments are—2 lycea, the Richelieu at Odessa, and the Bezboioko at Nezin; further, 84 gymnasia, each government and every important town having at least 1; 458 district, 1090 parish, 19 primary, 654 private, 2 veterinary, and 107 Hebrew schools. Total under this ministry, exclusive of Poland, 2434 schools, with 7472 teachers, and 104,164 scholars, at an annual outlay to the state of L.475,000.

Educational matters in Poland are under a curator, who reports both to the lieutenant of the kingdom and to the minister of public instruction. The Warsaw learned circle is the only one in the country, and under it formerly stood a university at Vilna; but it was suppressed in 1833 on account of the political troubles, and removed in 1839 to Keeyeff, the Vilna professors being bodily translated thither, and the former university at Keeyeff re-established under the name of St Vlodeemir. There exist at present in Poland 1 medico-chirurgical academy, 1 nobility institute, 1 government ladies' boarding-school, 1 school of arts, 6 philological gymnasia, 1 practical gymnasium, 2 practical high schools, 1 school of agriculture and forest economy, 181 private and 9 practical district schools; 17 district, 1 Sunday commercial, 1 primary teachers, 1119 primary, 93 Sunday artisans, 1 rabbinical, and 5 Hebrew schools. Total, 1441 places of education in Poland, with 74,343 scholars, the number of masters not being shown.

Education in Finland is under the secretary for that grand principality. It is provided for by 1 university at Helsingfors, 1 cadet corps at Friedrichshamm, 6 gymnasia, 14 upper elementary, 53 lower, and 25 Sunday-schools; further, 3 navigation, 3 technico-practical, and 3 commercial schools; 1 institute for rural economy, several people's schools, and 6 girls' schools; the total of masters being about 300, and of scholars 9000. Girls are mostly taught at home. No Fin is admitted to the sacrament unless he can read.

In 1849, only 917 books were printed in the whole empire, against 1626 printed in 1857, in the Russian, Polish, Finnish, Lettish, Esthonian, Gruzian, Armenian, German, French, Italian, and English languages. The number of

journals and periodicals issued in 1859 forms a total of 204. Piracy of literary property is punished by heavy fines, and copyright is inalienable for fifty years. Typography, as an art, although improving, is still in a backward state, and printing is dear. The greatest darkness prevails in the Caucasus and in Siberia; the greatest enlightenment, in the capitals and the Baltic provinces. It was through this German section of the empire, not to speak of the foreigners who co-operated in the work, that the country became permanently civilized.¹ Russia is still the great barrier against Asiatic barbarism, and the great means of Asiatic civilization.

Summary from the Statistical Tables of 1856.

	Schools.	Scholars.	Percentage of scholars of both sexes.
In the European governments and provinces	7841	432,889	0.75
In the Caucasian lieutenantcy	74	5,505	0.19
In the Siberian governments and provinces	312	11,608	0.35
In the whole empire	8227	450,002	0.70

On an average there fell to every government and province of the empire from 126 to 127 schools, and 6329 scholars; to every school 55 scholars; and in the whole empire 0.70 scholars to every 100 inhabitants of both sexes, —otherwise expressed, 1 scholar to 143 inhabitants.

Army.—The general direction of this branch of the service rests of course with the emperor; but the detailed direction is under the management of the Staff-Office, corresponding to the English Horse-Guards. In its organization the staff adheres mostly to the French. The officers of the staff are well versed in foreign languages; still their education calls for some amendment. There are many abuses of management, as well as much speculation, existing in the army generally; although, to the credit of the government be it said, commissions are nominated in regiments and elsewhere to inquire into and uproot abuses. The hospital service, during the recent war, was open to indignant animadversion. Promotion goes by seniority, favour, and for distinguished services; there is no putting of demerit over the head of merit by purchase; and every officer must serve from the rank of under-officer upwards. Young men educated in the military colleges come out as

¹ The discharged soldier in Russia is an important agent in the communication of that floating knowledge which goes so far to instruct a people.

Statistics. officers. The whole army is under a minister of war, assisted by a colleague and a military council. The office of Master of the Ordnance is generally filled by a grand prince. The total amount of the regular forces, reduced as it has been since the war of 1853-55, may be taken at 500,000 men; and the total of the irregular troops, consisting of the Kozzack forces and different militia troops, at 150,000 men. The following is a view of their composition:—

Regular Troops.—The active army consists (1.) of the separate corps of the Guards, comprising the infantry and reserve cavalry corps of the Guards; (2.) of the separate grenadier corps; (3.) of the 1st, 2d, 3d, 4th, 5th, and 6th corps, the three first forming the 1st army, and subordinate to its commander-in-chief; (4.) of the separate reserve cavalry corps; (5.) and of the following separate corps—the Caucasian, Orenburg, and Siberian; (6.) lastly, of the forces stationed in Eastern Siberia and in Finland.

Statement of Army.

Guard Corps.

2 Divisions of heavy cavalry ¹	Men.
1 " light "	4,000
3 " infantry	2,000
9 Batteries of foot artillery	36,000
4 " horse "	
The grenadier corps, and the 6 army corps, are each composed of—	
3 Divisions of infantry	252,000
1 " light cavalry	14,000
1 " foot artillery	
To each infantry corps is attached a division of foot artillery, and each division has 3 brigades, of which 1 brigade, composed of 4 batteries, is attached to each division of infantry.	
1 Brigade of horse artillery, composed of 2 batteries	4,000
The separate corps of reserve cavalry consists of 2 divisions of cuirassiers, which form the cadres for war-time; to this reserve cavalry are attached—	
6 Horse batteries	
1 Division of horse pioneers	250
<i>Separate Caucasian Corps.</i>	
4 Divisions (strong ones) of infantry

18 " " Grusian line	
6 " " Black Sea line	
Forming a total of 139 battalions, equal to..	
170,000	
Grand total	482,250

The regular troops included in the separate corps of Orenburg, Siberia, and Finland, with the artillerists, &c., will swell this amount to about 500,000 men. The irregular troops cannot be estimated with any degree of exactness on account of their peculiar organization, no permanent contingent being fixed, and the whole male population being in some parts liable to serve when summoned.

The recruiting is effected by alternate levies made in the different governments, and ordered by imperial command, designating the classes and the number of men to be taken from every thousand. Recruits are chosen by the communes or selected by lot, and are received by a commission in the presence of an imperial aide-de-camp. The nobility, officials, clergy, and merchants, are exempted from serving; the recruitment thus falls mostly upon the serfs between the ages of 18 and 35. The term of service is 20 years for the Guards, 22 for the line, and 25 for the train and military servants, although unlimited furloughs are given earlier. Every year after the manœuvres, which take place at different times and places, the minister of

war demands of the regimental chiefs what soldiers may be dismissed; but the principles on which furloughs, limited or unlimited, are granted, do not, from their complication, admit of detail. The general rule is, in case of war being expected, to give leave of absence only to such soldiers as are natives of the nearer governments, in order that they may be promptly called in when needed; but if war should not be expected, then the soldiers are dismissed to the remoter governments, though always liable to be summoned to the ranks so long as physical capacity allows. The furloughed soldiers must, on arrival at their homes, report themselves at the dépôt of the nearest regiment, no matter that it is not their own, and every year appear at the nearest place appointed for manœuvres and drill, which never last beyond a few weeks. Little or no pension is given, but the old soldiers are emancipated as serfs, and provided for by being preferentially appointed to situations as doorkeepers, watchmen, overseers, and so forth, in government establishments and public institutions. There are but few hospitals for invalided soldiers; the chief one is at Tchesma, near St Petersburg. The Russian soldier of the Guards is tall and well made; but the line-soldier is often narrow-chested, has not so much strength or stamina, and he is but very indifferently fed in war, which explains why he dies so fast on march and in hospitals. The Russian is hardly beyond compare, and most unquestionably brave; but his bravery is of a stoical kind, totally differing from the fury of the French, and more resembling the intrepidity of the English soldier, which has no equal. His favourite weapon is the bayonet, which, like the Englishman, he takes to naturally, because used from infancy to the hatchet and to chopping. The Russian soldier can be his own cook, tailor, and bootmaker; he is handy to a degree, and enduring to martyrdom; but he wants that high tone of spirit which is imparted only by moral superiority, and this is the reason why his education is now being more attended to; the officers themselves being made, throughout the Guards and army, the schoolmasters of their men, who learn, good-humouredly and successfully, reading, writing, and the rudiments of arithmetic. The men are now also taught gymnastic exercises, besides bayonet and sword-play. Every battalion has a proportionate number of special marksmen with rifles, who are taught musketry-practice. The men are much more liberally treated than before the war of 1853-55, and the drill and exercise system is greatly altered, the automaton system having been found of bad effect, serving only to stupify. The Kozzacks, the artillery, the cavalry, and infantry regiments of the Guards, are composed of fine men. The favourite mode of attack is in column; in Soovòroff's time it used to be in line, like the English. The immense spaces to be traversed, and the distance from dépôts, neutralizes one-third of the active force. Railways, however, are altering this state of things.

The engineers are perhaps the most learned of all the army. The Guard officers are gentlemanly in tone, and well educated, the artillery and staff particularly. Krupp's steel cannon is used in the Caucasus, and has proved itself a good weapon of war, although a costly one. The percussion-lock has long been adapted throughout the army to a plain bore, with the Minié ball. The artillery is very fine, and the horses are strong; but the powder is bad. This arm manœuvres well, is bold in advance, and fires quickly. The cavalry is admirable, the Kozzacks making excellent light troops, through the hardness of their horses and their equipment being suited to its purpose. It is the Kozzacks of the Caucasian line and of the Black Sea who are the best and bravest; the other Kozzacks are but indifferent

Statistics troops. The arsenals, powder-mills, and great military manufactories are at St Petersburg, Systerback, Toola, and Petrozavodsk. Dark-green is the prevailing colour, often with red facings, but blue and other colours are also affected. One-half of the income of the empire was supposed to be applied to the former war budget, but retrenchments of great magnitude have been made since the last war. The numerical amount of the army is rigidly kept secret, as a supposed means of strength.

§ Memory of Azoff.

It is asserted that the light craft in the Black Sea are so built as to be easily convertible into vessels of war. There are, further, a few steamers, corvettes, and transports built in the United States for the Amoor service.

As hereby appears, the Baltic fleet is at present the only

important one in the empire, and forms the nucleus of the Russian navy. The life of a Russian-built ship is ten years, and no more. The American-built vessels ordered for Russia, though infinitely dearer, live at least three times that term. The number of men actually serving in the

children of soldiers were forcibly brought up as scribes, and for service in the line, thus forming a positive caste, from which there was no escape. The military schools provide education for the same class without entailing any such bondage. The military colonies have also been done away with, as a mighty failure, candidly avowed, and the colonists are merged into the population.

Statistics.

Russian fleet may be computed at about 38,000; but in point of fact the number is next to illimitable, for it can be augmented at will by drafts from the land force. Regard is certainly, in some degree, had to the provinces from which ships' crews are taken, but little positive good, through different causes, is on the whole derived from this measure; the chief reason being, that Nature herself is against Russia's ever being a great naval power, although she may be, and is, a considerable one. So long as her ports freeze up for half the year, so long will Russia possess only a second-rate navy. The fleet itself is now divided into three divisions,—the blue, white, and red. Cronstadt is the permanent harbour. The national navy flag is a blue cross transversing a white field. The marine is presided over by a minister, assisted by a colleague and an admiralty council. This forms the highest administration of the navy. The other departments are,—the general auditoriat, which is the highest naval court; the auditoriat department is its executive branch; the minister's chancery serves to link the administration with the departments, and transmits orders to them; the inspector's department checks accounts, exercises a general supervision over the navy, and is the managing section. The other divisions are,—the medical, building, ship-building, hydrographic, and commissariat departments; a scientific committee; a committee for the steam-engine service; and besides these, at Nicholaeff, a hydrographic section, but on a small scale. The ship-timber department is under the minister of crown domains. The hospitals are numerous, well provided, and sufficient, were they only well conducted.

There are now no English officers in the Russian fleet: formerly, under Peter, Catherine, and Alexander, they contributed to make the Russian navy what it now is.

Ministry of the Interior.

This ministry, answering to the English Home Office, is one of the most important branches of state-administration, embracing internal economy and police superintendence, besides the management of the medical department and of matters relating to the foreign religious denominations. It consists of the following departments:—(1.) General matters and the minister's chancery, in which are concentrated all affairs relating to the persons composing this extensive ministry,—i.e., the nomination of governors, town-chiefs, and so forth; to peasants applying for their emancipation, and to the sectarians. (2.) The executive police, charged with the correspondence relating to the repairing of roads, the prisons, alms-houses, the arrangement of corn-magazines in towns and manors, excepting the lands of the crown peasants, the land-rates and their outlay, the recruitment, the town and land-police, the nobility elections, and generally to events occurring in all parts of the empire, excepting Poland and Finland. The economical department has the management of all matters relating to the financial economy of the towns throughout the empire, again excepting Poland and Finland; to the town-halls, the merchant guilds, arti-

zans' companies, and burghers' corporations. This department has also the management of the committees of public supervision and of their funds. It is here necessary to explain that these committees manage the affairs of the charitable institutions, such as alms-houses, hospitals, &c., in every government; and at the same time form financial credit establishments, which receive sums of money on interest, and lend them out again, the profits on which transactions are made over to the charitable institutions. Under the department of foreign religious denominations are placed all their consistories, schools, and other establishments. This ministry has further a council for very important affairs, and a statistical committee. To the latter are entrusted all matters relating to statistical information, and the reports of governors concerning the state of affairs in all parts of the governments confided to their rule.

Statistics.

The highest instance in medical administration is the Medicine. medical council in St Petersburg, under the minister of the interior. The medical service is divided into three parts: (1.) The civil medical service. For this there exist a medical department, and a separate department for supplying all the medical establishments with drugs and other means of treatment. To this department belong a manufactory of surgical instruments, and five warehouses for medicaments in different towns, and with botanical gardens. In every governmental town there is a medical administration, consisting of three members, an inspector, an operator, and an accoucheur; in every smaller town, a district physician; and in most of them a physician for the town hospital. In both capitals spacious hospitals are founded, either at the expense of the crown or of private individuals and societies. (2.) The army medical service has a medico-chirurgical academy, with a scientific committee. Each army—the northern, southern, and the army of the Caucasus—has a general staff-doctor; and each corps, division, brigade, regiment, and battalion, also each military educational establishment, has its physician. (3.) The naval medical service resembles that of the army. There is a department, and a medical inspector for the Black Sea navy; and each naval division, ship, and sea-port hospital has one or more physicians, as required. The crown and appanage peasants, the manufactories and foundries, are all provided with physicians depending on the respective ministries. At each of the universities, with the exception of St Petersburg, there are faculties for medical students, with professors, anatomical cabinets, and clinical institutions. In lieu of the medical faculty there is in St Petersburg a medico-chirurgical academy. Another such academy has recently been established at Warsaw. Both in the universities and academies there are students of pharmacy. The veterinary schools are three in number; and there are schools for hospital-dressers connected with all the larger hospitals. Every one desirous of obtaining a license to practice in medicine or the veterinary art must pass an examination in one of the universities or academies. The lowest degree is that of *lékar* (medical practitioner); then follows that of doctor of medicine; and the highest is that of doctor of medicine and surgery. As for pharmaceuticals, young persons are engaged by private apothecaries as apprentices for a term of four or five years, and they afterwards pass an examination as pharmaceutical assistants, then as provisors. The highest degree is that of magister of pharmacy: the two latter degrees entitle them to keep an apothecary's shop of their own. There are two principal lunatic asylums; one near St Petersburg, with 240, and the other at Moscow, with about the same number of beds. Besides these, in every governmental town there are hospitals under the inspection of the committee of public supervision, with separate rooms for the reception of the insane. The large asylums are well provided with all the means requisite for the successful treatment of patients. Not so the hospitals

Lunatic asylums.

Statistics. in the provincial towns, which are totally destitute of every needful appliance. Private asylums, under strict government control, have been established at different times in both capitals, but they never succeeded, and have seldom lasted long. The number of persons attacked with mental derangement having increased of late years to an awful extent, especially during and after the war, the attention of the government was directed to this point; and in the winter of 1857-58, a committee, consisting of medical men and some superior civil officers, under the presidency of Dr Marcus, was formed, in order to deliberate upon the measures to be taken for the future. The opinion returned was, that eight central lunatic asylums were indispensable in Russia, besides those already existing in the greater provincial towns; that these asylums should be provided in the best manner, and considered as practical schools for young medical men in order to prepare them for their future calling,—*i.e.*, physicians-in-chief of lunatic asylums, to be subsequently founded in each governmental town. It is not yet known whether government will confirm the measures proposed. In 1856, no fewer than 3616 cases of mental derangement were medically treated throughout the empire, both in the lunatic asylums and other civil hospitals. Of these, 2078 either recovered, or were dismissed as such, 288 died, and 1150 remained. This most happy result must surprise every one who is conversant with such matters; but it may be partly explained by what is designedly said in the report, that a sixth of the cases were such as are called in England brain-fever of drunkenness, or *delirium tremens*; a disease which in Russia is considered as insanity, and the treatment of which is generally successful. Still the veracity of the report is to be doubted.

Canals.

The navigable water-ways of communication, uniting the Baltic and White Seas with the Caspian, form the so-called eastern system. Of these water-ways, the most important is the one uniting the Baltic with the Caspian. It consists of three systems: the Veeshni-Voldtski, the Tèekhvín, and the Maria. (1.) The Veeshni-Voldtski system is formed by the Neva, the Ladoga Canal, the Novgorod or Siever's Canal, the Alsta, Lake Alstino, the Veeshni-Voldtski Canal, the Tvertsa, and the Volga. Its length from Petersburg to Ribinsk is 868 miles. (2.) The Tèekhvín system is formed by the Neva, the Ladoga, and Siasski canals, the Siass, the Tèekhvinka, Lake Èglino, the Tèekhvín Canal, the Voltchina, Lake Sòmino, the Sòmino, Lake Vozensk, the Gorioon, Tchagodòstcha, Mòloga, and Volga. Its length is 561 miles. (3.) The Maria system is formed by the Neva, the Ladoga, Siasski, and Sveer Canals, the Sveer, the Onega Canal, the Vcetegria, the Maria Canal, the Kovza, the Bielozèr Canal, the Sheksna, and the Volga. Its length is 699 miles. The water-way from the White Sea to the Baltic and Caspian is formed by the Northern Dveena, the Sookhòna, Lake Kòðensk, the Porogovètsa, the Duke of Wurtenberg Canal, and the Sheksna; whence it branches off on the right to the Neva, and on the left to the Volga. The Moscow Canal has been dug betwixt the upper courses of the Moskvà and Volga.

The water-way from the Baltic to the Black Sea is formed by three systems: the Berèzina, the Ogheen, and the Dniepro-Boog, and is called the western system. (1.) The Berèzina system is formed by the Western

Dveena, the Oollah, Lake Leppel, the Essa, and Berèshita, Lake Berèshita, the Berèzina Canal, Lake Flavio, and the rivers Sergootch, Berèzina, and Dniepr. (2.) The Ogghinsk system is formed by the Niemen, the Shara, the Ogghin Canal, the Yasselda, Priepetz, and Dniepr. (3.) The Dniepro-Boog system is formed by the Vistula, Nareff Boog, Mookhaletz, the Dniepro-Boog Canal, the Peena, Priepetz, and Dniepr. The Vistula and Niemen are also united by the Augustovo Canal betwixt the Netta, which falls into the Bobr, an affluent of the Nareff, and the River Gàntcha, which runs into the Niemen. There are many smaller canals in Finland and the Baltic provinces.

The national debt of Russia amounted on the 1st January Finance. 1859 to a sum of L 140,000,000, viz. :—

(a) Dutch loan at 5 per cent	L.3,752,375
(b.) Foreign loans, at 5, 4½, and 4 per cent, without a term	53,119,622
(c.) Interior loans, to credit institutions, at 4 per cent.	68,830,000
(d) Exchequer bills, at 4½ per cent.	14,500,000

Total L.140,201,997

The 4 per cent. consolidated bill issue, announced on the 23d March 1859, is not a new loan, but only a consolidation of deposits, or substitution of one kind of value for another. A part object is to reform the vicious system which prevails at the banks. The amount, intended to reach 125 millions sterling, can be liquidated at the end of 56 years. Should the present measure succeed, the old order of things may be looked upon as superseded, and special mention of the banking returns is therefore superfluous, because the old system is now antiquated. The curious on this subject, as well as on the paper system of the country, would do best to consult at length Lamanski's very able works on Russian finance.

Statistics.

The national income is presumed to be from 36 to 39 millions sterling. The expenditure amounts to the same sum, and for the last twenty years has generally exceeded it. This order of things gave birth to continual loans of the public banks, and to an unexampled emission of paper money, which amounted on the 1st January 1858 to a sum of more than 115 millions sterling, having been increased during the late war, and up to 1857, by more than 62 millions sterling. Since that year no fresh issues have been made. The amount of bullion formed, at the same period, a sum of 18 millions sterling, both in gold and silver. The exchange of the so-called credit bills, notwithstanding the large amount of bullion, takes place not, or only exceptionally, from a fear on the part of the government that a large portion of it, were the bills payable at call, would be exported.

The chief sources of revenue are :—1. The monopol-right of selling brandy. This right is sold for a term of four years by auction, which takes place at St Petersburg, where the prices for every province are settled separately. This monopol-right has been sold for the next four years, 1859–63, for an annual revenue of 18 millions sterling. 2. The capitation-tax, paid by every person, of all ages, of the male population, and by all classes except the nobility, clergy, and merchants inscribed in guilds, or by special classes. This personal tax is laid on the male population found in life at the period of the census, and its amount is never changed until a new census is taken. Children born after the census pay no taxes. The survivors pay for the dead. The amount of this tax is L.8,000,000. 3. The import duties give a sum of L.4,000,000. 4. Miscellaneous

unfixed taxes, L.3,270,000,—viz., (a.) Patents for trade, L.590,000; passes and road passes, L.310,000; (b.) Stamp-duties, L.1,070,090; (c.) Court and chancery duties, L.680,000; and (d.) Post revenue, L.620,000. 5. The salt taxes, and mineral taxes on gold and other mineral productions, 4½ millions sterling. The civil list, or court expenditure, is supposed to amount to L.1,700,000, towards which the peasants of the appanages and crown domains contribute about L.600,000.

The trading ports on the German coast of the Baltic are St Petersburg, with its port of Cronstadt, Narva, Revel, Arensburg, Pernau, Riga, Windau, and Liebau. Of these ports, the first two are frozen up for six months; but the latter are much longer open to navigation, according to the season, generally for ten months, more or less. On the Finnish coast, Wyburg, Lovisa, Helsingfors, Abo, Nystad, New Carleby, and Torneo; on the Arctic Ocean, Kola; on the White Sea, Arkhangel and Onega; Petro Pavlovsk, on the Kamtchatkan Sea; and on the North Pacific, Sitkha, the capital of the possessions of the American Company; on the Sea of Azoff, Taganrog, Mariúpol, Kertch, Berdiansk; on the Black Sea, Odessa, Theodosia; on the Caspian, Astrakhan, Bakoo, Derbent. The port of Nicholaieff, at the mouth of the Amoor, on the Gulf of Tartary, has just commenced its prospectively splendid career. The chief articles of export are corn and grain, hemp and linseed; also hemp and linseed oils, tallow, hemp, flax, iron, copper, timber, potashes, bristles, furs, hides, and isinglass. There are no free ports at present in Russia except Nicholaieff, on the Amoor. Odessa was, but is no more.

Foreign trade.

A Statement of the Quantities and Value of Merchandise imported into Russia from Countries in Europe, and from America, in the year 1857.

Description	By the Tariff of 1857 Quantities.	Value. ¹
Merchandise imported paying no duty.		L.1,538,289
Merchandise on which one and the same duty is levied at 20 cop. (=7½d.) per pood (36 lb) (cwt)	38,374	156,172
Merchandise paying different duties:—		
Provisions and victuals (colonial merchandise:—		
Coffee, raw sugar, pepper, &c. (cwt)	365,576	1,008,093
Wines, liquors, porter, beer, mead, &c. (cwt.)	159,064	
Kirschwasser	9,675	
Champagne and other	736,385	881,668
Wines	222,153	
Mead, porter, beer.	149,061	
Vegetables and fruits (cwt.)	15,629,606	415,500
Oranges, lemons, &c. (No.)		
Cherries, pears, apples, &c. . . (casks)	7,744	
Fish and herrings (cwt.)	147,944	312,010
Herrings (casks)		
Cattle (heads)		
Grain,—wheat, rye, barley, groats, &c. (cwt)	33,463	62,764
Do. do. (qrs.)	1,239	
Salt (cwt.)	1,447,082	357,317
Olive oil	176	607
Tobacco	30,842	343,992
Various provisions and victuals, such as cheese, mustard, vinegar, oysters, mushrooms, treacle, sweet-meats, &c.		93,819
Total		L.5,170,231
Raw materials and other articles for manufacturing and agricultural produce:—		
Dyestuffs and colours (cwt.)	316,466	1,158,765
Metals	136,654	205,357

Description.	By the Tariff of 1857. Quantities.	Value.
Chemical materials and produce (cwt.)	196,417	L.248,326

Manufactory and other produce:—		
Gum-elastic and gutta percha (cwt)	1,307	24,765
Wooden articles, playthings, furniture, &c. (cwt.)	4,727	32,805
Instruments,—musical, mathematical, astronomical, &c. (cwt.)	407	
Do. do. (No)	5,763	50,458
Leather produce. (cwt)	487	37,053
Metal articles	69,631	362,824
Glass and crystals.	4,281	
Bottles (No.)	4,667	57,651
Plate-glass and mirrors	10,561	
Woven produce of cotton, silk, wool, hemp, &c. (cwt.)	29,458	
Coarse linen bags (No.)	10,552	
Turkish fez caps	5,978	1,650,283
Turkish cotton and silk stuffs . . (yds)	106,753	

¹ In translating Russian values into English, the L.1 sterling has been calculated throughout at 6 roubles 40 copecks, its average equivalent; the pood, or standard of weight, at 36—113 lb. avoirdupois; and the arscheen, or unit of length, at 2333 feet. The immense labour which attends the reduction of foreign values into corresponding English might be entirely spared to the compiler of statistics by the adoption of a universal system of decimal measures, weights, and coins.

St Petersburg, 1858	L 647,743
Exported.....	3,565,136

The tables of foreign trade show that from 1843 to 1857 the value of importations, as well as of exportations, has constantly augmented, both for Europe and Asia; and that in the European trade, excepting the years 1851, 1854, and 1855, the Russian exports have constantly surpassed the imports.

In 1857 the amount of confiscated merchandise sold was L.118,183; and as contraband trade could not subsist if more than 20 per cent. of fraudulently-imported merchandise were to be confiscated, it must be supposed that at least L.600,000 worth was introduced into the country. The sole means of preventing contraband trade is to lower the tariff.

Total.	L.34,756,268	L 23,799,407

This table shows that, as regards the trade with Asia, the value of the exports has constantly been inferior to that of the imports, and that for these fifteen years the difference amounts to a total of L.10,956,961. This, however, is more than compensated by the larger amount of exportations over importations in the European trade, the former exceeding the latter by L.47,290,240; so that the total difference in favour of Russia is L.36,333,243, on an amount of capital turned over of L.452,739,853, of which sum L.208,213,805 go to the account of importations, and L.244,526,548 of exportations.

Peter would perhaps have done better had he founded his capital at Windau or Liebau, for the sake of more open water; but political considerations no doubt prevented him, as all his designs show foresight enough. Nearly the same result will now be attained by the railroads in course of construction.

The first company in Russia was established in 1790. The number of existing companies now amounts to 90. The original capital of all these companies amounts to about L.69,669,016, in which sum the chief company of Russian railroads figures for L.48,437,500.

The number of Russian merchant-vessels is supposed to be about 2000, including coasters, small craft, and steamers; but there are as yet no reliable returns; and until these be issued by the proper authorities, it would be entirely vain to aim at anything like a correct estimate of the Russian shipping.

Number of Russian and Foreign Vessels entered and cleared at the Northern and Southern Ports of Russia in 1857. Statistics.

It is now only in consequence of Count Renaud de Chevancy's recent invention of an international marine telegraph, indicated by numbers, that Russian vessels are at last being counted, measured, and formally tabulated. The following returns are authentic:—

Grand Total of the Russian Commercial Fleet at 1st January 1858.

	Sea Going.		Coasters.		Total.	
	Vessels	Lasts	Vessels	Lasts.	Vessels	Lasts.
In the Black Sea	25	5,070	160	9,580	185	14,650
„ Sea of Azoff. ...	13	1,330	291	10,670	304	12,000
„ White Sea	128	4,781½	212	4,922½	340	9,704
The colonial fleet (vessels of the Russo-American Company) }	13	2,368	13	2,368
On the German side of the Baltic	107	9,451	150	4,107	257	13,558
	286	23,000½	513	29,279½	1,099	52,280½
¹ Or, 104,560 tons.						

In this total, for want of data, are not included the vessels belonging to the port of St Petersburg, to Finland, and to the Caspian Sea. The total number of registered sailors was only 5000, viz.:—In the Black and Azoff seas, 2300; in the White, 1620; in the employ of the Russo-American Company, about 300; in the Baltic, 1000. This number of sailors is most likely much below the mark. In the Baltic there were 30 foreign masters, mates, and pilots, besides 112 foreign sailors registered; but the legal proportion of foreign to native sailors (1 to 3) is never observed, the law obeyed being solely that of necessity. The causes of the little progress made in ship-holding affairs are insufficient education, vexatious over-government, the stupid passport system, the want of sea-insurance companies, and generally the manifold reasons which impede the development of the foreign trade. Compared with every other branch of national economy, the shipping interest may be said to have progressed in a ratio inverse to them. It will be observed from the above table, that the number of sea-going vessels is exceeded by the number of coasters in the proportion of nearly three to one; while the tonnage or lastage of the two are pretty nearly equal. But one can scarcely venture with safety upon any remarks regarding the state of the Russian shipping, while the exact returns remain undeclared for St Petersburg, Finland, and the Caspian Sea.

The following return of figures will best show the state of the manufactures, internal trade, and productiveness of the empire. Productive Industry.

The value of cotton-twist produced in 1858 was at least L.10,937,500, and it continues to increase rapidly. At present there are 480 mills, with 1,500,000 spindles. The linen manufactures, however, are rather declining. The woollen productions are estimated at L.7,031,250, and there are 640 cloth manufactories. The flax and hemp produce amounts to L.9,375,000, with 290 manufactories. Silk produce, L.937,500 (this return is obviously exaggerated); manufactories, 250. Tanneries and leather manufactories, 2060; produce, L.1,562,500. Paper manufactories, 180; produce, L.781,255. Distilleries, 800; brandy produce, 46,800,000 gallons; value, L.2,560,000. Licensed public-houses, 1899. At present, in consequence of the temperance movement, mostly beer and mead are drunk there.

It should be observed that, not as in France, where from vanity the manufacturers exaggerate the amount of their produce, the Russians generally return figures below the actual amount, perhaps from a fear of additional imposts.

Trade returns at Neezhne-Novgorod fair:—In 1857, of L.13,435,050 value brought, there was sold L.12,247,100; in 1858, of L.44,838,180 brought, was sold L.13,719,190.

Fair of Irbit (in Western Siberia):—Value of merchandise sold in 1859:—

Horses	3,400
Total..	L.6,660,600

In the government of Keeyeff a common plant, called the *Asclepias syriaca*, is being cultivated for the cotton-like tissue it produces.

Tcheffkin's work (written in 1851) gives the following statistics of the mining produce:—The whole quantity of pure gold won from sands and mines since the middle of the last century up to 1850, was 869,630 lb. troy. It is in the Asiatic governments of Perm, Orenburg, Tomsk, Yeniseysk, Irkootsk, and the Keergheez lands, that the gold is mostly found. In the government of Orenburg at present, in 1859, so many as 10,000 workmen are employed in this branch of industry, and the yearly produce for private account is 4370 lb. troy of the metal.

Lead and Silver Ore.—The lead produced barely suffices for the extraction of the silver required; in aid of which purpose 402 tons of foreign lead was not long ago sent up on trial to the Altai foundries, at a cost-price of L.15, 10s., and a further charge for carriage of L.10, 8s. per ton. Improvements are taking place in the working of these mines. and the veins of silver-lead ore lately discovered promise well for the future. The ore at Nertchinsk contained 9·7 oz. of silver, and about 168 lb. of lead in the ton.

Up to 1850 the whole quantity of pure silver won from the mines in Russia, chiefly in the Altai and Nertchinsk foundries, was 4,704,418 lb. troy.

Between 1826 and 1850, in the course of 24 years, the value of the gold and silver won was	L.41,478,750
Imported from abroad in bars and foreign coins.	7,072,800
Exported	27,229,690
Deducting this export there remained, won and imported	61,635,640
Of which were delivered to the Mint	59,104,400
Coined	L.48,258,400
Cast into medals	240,300
Re-delivered in bars.....	6,097,300
	54,596,000

The difference between the in- and out-going amounts is accounted for by the circumstance of the Mint retaining a considerable portion of the metal which it receives, either for re-coinage or for delivery in the next year.

The whole amount of Russian bullion up to 1850 may be taken at:—

In gold	L.26,625,000
In silver.....	20,781,000
Total	L.47,406,000

And adding hereto the amount coined in 1850, at the average rate of the five years preceding, say L.3,281,000, the sum total of Russian gold and silver bullion may be taken, up to the beginning of 1851, at L.50,687,000.

Of this amount more than fifteen millions are deposited in the expedition of credit-bills (bank-notes or assignats), the current paper-money, and more than L.34,375,000 must be in circulation. Considering the national custom of hoarding and burying money, particularly bullion, this amount, although large, is not perhaps sufficient.

Between 1826 and 1850 the amount of foreign bullion imported was	L.16,196,250
Exported	3,999,060

Balance..... L.12,197,190

This remarkably larger import of foreign bullion, compared to the export, is the more noteworthy that it did not decrease during 1843 and 1848, when the demand abroad for Russian gold and silver was so unusual as to cause the

Statistics.

government partially to prohibit the export, which was again permitted only in November 1849. A large portion of the foreign bullion, however, is converted into bars for purposes of trade, re-coined into Russian money, or used in articles of jewellery; so that the amount remaining in circulation can hardly be taken at more than one-fourth of the above quantity,—i.e., L.3,000,000. Including this latter sum, the whole mass of gold and silver coin at present circulating in Russia may be estimated at L.53,687,000.

Platina.—Since the time of its discovery in 1824 up to 1858,—89,563 lb. troy had been won, at the rate of 3·7 lb. avoird. from every ton of sand. The disuse of this metal as money has induced the owners of platina-yielding deposits to abandon the search, although much more might yet be obtained.

Copper.—The average of the ten years between 1841 and 1851 showed that about 14,872 cwt. of copper are yearly smelted in all Russia.

Lake-Salt.—The same decennial period showed a yearly return of 6,601,000 cwt. of lake-salt.

Coal.—The quantity yearly won was only 1,017,520 cwt., chiefly in the south of Russia, and in the land of the Don Kozzacks. Numerous veins have been discovered in Central Russia, the Caucasus, and Siberia. The import of English coal was 4,830,000 cwt. This mineral will soon be produced in larger quantities.

It is conjointly with coal that the production of other metals, excepting gold, takes place; and as the coal branch of industry has not yet attained to so much as the first stage of its proper development, the other metals are in a similar backward state. Russia produces gold, silver, copper, iron, lake-salt, and, in a small quantity, platina, lead, coal, and anthracite. In the Nertchinsk district there are indeed mines of tin, cinnabar, and zinc; but they are not worked on account of their distance and poorness. To speak now of iron, as of that metal on which the successful cultivation of the chief branches of industry is to such an extent founded, that the quantity of iron won and consumed might be taken as the best gauge of a country's industrious development:—

By the decennial average of 1840–50, the government foundries produce annually of	Cwt.
cast-iron about	644,000
And the private foundries.....	3,570,336

Total..... 4,214,336

Of which latter quantity, 2,973,140 cwt. were forged into iron. Of late years this branch of industry is increasing; the difference between 1832 and 1849 being 30 per cent. The demand for iron in the interior is so great that, notwithstanding the increased import from Poland and Finland, as well as the sensible falling off in the exportation abroad of Russian iron, prices have still risen.

In 1838 the average wholesale price of bar-iron throughout the empire was.....	Per cwt. 15s. 2d.
Retail.....	16s. 0d.
And in 1843 wholesale.....	15s. 6d.
" " retail.....	16s. 4d.

Consequently in five years the average price had increased by 4d. The price for sorted iron was yet higher; and subsequently to 1843 prices had gone on rising; as, for instance, in Moscow, for 1846 and 1847, iron cost 14s. 2d. per cwt., but in 1848 and 1849 it cost 17s. 8d.; at Taganrog the proportion was 11s. 6d. to 13s.; and in Odessa 15s. to 15s. 6d. The average price of bar-iron in 1851 was in Prussia 12s. 4d., in France 10s. 6d., in Belgium 9s. 6d., and in England 5s. 2d. per cwt.; Welsh iron costing there only 4s. 4d. per cwt. Experience shows, as well in Russia as abroad, that no marked increase in the production of cheap iron can take place until coal is called in to aid this branch of industry. The difference in cheapness between the cost of iron produced by the agency of pit and charcoal

Statistics. was in France alone 30 per cent. In Russia this want of charcoal fuel is becoming more and more sensibly felt; and the foundries in the governments of Toola and Tamboff have already been closed on account of the thinning of the woods; but Providence seems likely to help the country in this respect, as coal veins will soon be largely worked in the government of Yekaterinoslaff, on the Sea of Azoff. The Ooral foundries possess the finest ore, particularly magnetic; yet notwithstanding its adaptation to steel and wire, the importation from abroad increases; as does also that of machinery, which in 1841 was for L.35,780, in 1846 for L.201,720, and in 1849 for L.293,590.

Husbandry is still in a very backward state. Rotation of crops is the system mostly followed, but ignorantly, and

not by any means so profitably as might be the case. As many crops are taken out of the soil as it will yield, and then it lies fallow for a year or two. The Russians say that this state of things is best suited to the ignorance of the peasants, who have no instructors, and to the great quantity of land allowed them to till. The model farms established in most of the governments are slowly doing a small amount of good. In a few of these agricultural schools, steam apparatus have been tried; but the application of steam to husbandry is known only by hearsay. That agriculture might be rendered a very profitable branch of industry, is evident from the results obtained by the German colonists, who thrive prodigiously; and by the Quakers who have cultivated land in the neighbourhood of St Petersburg. All have succeeded eminently in their undertakings.

According to calculations carefully collated in 1849 by the agricultural department, the quantity of winter and spring corn produced in Russia amounted to 168,000,000 qrs. There were 189,000,000 acres of arable land; 63,750,000 acres were used for winter and 63,750,000 acres for spring corn. The medium return of corn throughout the empire was four-fold, or about 10 bushels to the acre. The return of crop-produce may be calculated as follows:—Rye, 83,000,000 qrs.; wheat, 23,000,000 qrs.; oats, 42,000,000 qrs.; barley, pease, chives, buckwheat, and maize, 31,000,000; potatoes, 14,000,000 qrs.; linseed, 1,500,000 qrs.; flax, 432,000,000 lbs. avoird.; hemp, 288,000,000 lbs.; sugar beet-root, 11,000,000 cwt.; tobacco, 354,200 cwt.; silk, 9660 cwt.

Table showing the Quantities of Horses, Horned Cattle, Sheep, and other Animals in Russia in the year 1856.

Horses and Horned Cattle.	In the European Governments and Land.	In the Caucasian Lieutenantcy.	In the Siberian Provinces.	Total.
Horses.	15,065,750	469,522	3,030,011	18,571,283
Horned cattle.	21,732,787	2,024,022	2,463,013	26,219,822
Stags.	139,760	..	292,582	432,342
Camels.	31,023	24,885	3,929	59,837
Asses, mules, &c.	2,026	24,322	..	26,348
* Sheep.	41,484,938	4,425,443	6,250,651	52,161,032
Swine.	8,808,435	428,375	516,990	9,753,800
Goats.	1,364,962	108,662	220,505	1,694,129
Grand total.	88,629,681	7,505,231	12,783,681	108,918,593
* Of this number about 8,000,000 were of the so-called fine-fleeced sort.				

The Russian is charitable, kindly of nature, and hospitable. Respectful, obliging, and content with little, he is honest enough in the country, but in town he sadly alters, losing most of his good, and acquiring none but bad qualities. He possesses the imitative faculty in an extreme degree, but not the inventive. An early riser, he can work well when put to it, and has but few wants. He is better than his master the noble. The dark side of the picture is, that he will lie remorselessly; is sly, false, and insincere; lazy when possible; fond of drink; and he rather enjoys uncleanness, although his hot bath once a week is an example well worthy of being followed, because greatly contributing to his extreme longevity. Civilized, the Russian becomes a great thief. The temperance movement that has lately taken place in the semi-Polish and central governments is very remarkable, and is spreading widely. It originated with the Polish clergy (to their honour be it spoken), and was favoured by the badness of the brandy. Tall of stature and straight-limbed, the Russian is tolerably strong, robust, hardy, and not much subject to disease, through his out-of-door life during the greatest part of the year, and the continual exercise which

Statistics. the vastness of all things Russian,—embracing as well every object as every degree of distance,—forces him, against his will, to take. He is mostly fair of complexion, hairy, and bearded, pug-nosed, and rather small-eyed; but his good-humoured bearing and healthy look lend him a degree of handsomeness. The women are, alas, inferior to the men, being far from pretty; and even the beauty of youth fades with them much earlier than they could wish. The female population is likewise weakly, and much earlier broken down, through excessive labour in the fields, which, though a shame to the men, is a forced consequence of the imprisonment called conscription. Some few governments, however, are noted for their healthy, pretty-faced girls. Many men and women of huge proportions are to be met with; but there is more fat than muscle about them. Several of the strongest men of modern times were, however, Russians,—Orloffsky and Lookeën. The Russian man is the best specimen of the Slavonian race; the woman, not. The Russian has more real patriotism, too, than the vapouring Pole, who will sacrifice his country to his personal loves and hatreds; the Polish women, however, are superior to the Russian.¹

Dress and food. A red or blue linen shirt, linen drawers, boots worn over very wide trousers, often mat or bast sandals, a cloth kaftan bound by a sash, the national sheep-skin *tooloop* or body-coat, with various descriptions of head-coverings, form the simple dress of the men. The hair is cut round. The women wear boddices, coloured jackets called *sarafans* or *katsavaykas*, and *kokòshniks* for the head. This national dress is exceedingly becoming, and is very properly used at court. The *kokòshnik*, set with brilliants, is a magnificent head-dress, and the other parts of the costume admit of much elegance of display. Girls wear *kossàs* or plaited tails to their heads. Married women tie up their hair, which is mostly coarse, in gaudy-coloured handkerchiefs. In one word, the national garb is pretty, useful, and has a peculiar type. The food is simple. It chiefly consists of rye bread called *black*, always soup, curds, much milk, seldom meat, many vegetables, different farinaceous dishes, sundry *peerògs* or pasties, jams, preserves, and marmalades. The *kwas*, a sour small beer, unhopped, is a horrible drink; but the *bràga* and the *mors* (cranberry juice sweetened—the mead of the country), the *donskoy*, and various home-made wines, are delicious beverages. Tea and coffee are becoming more and more used. The former is said to be better than in England, through its being transported over land; but it is more likely that it is a different sort. The white-flour bread is excellent; the meat and mutton small, but sweet. The cabbage-soup, called *stohee*, the Little Russian *borstch*, the *porosòdnok*, or pickled sucking-pig,—all used with sour or clotted cream; the *koolibràk*, an egg and fish or meat pie; the *rastiagài*, a little meat pasty; the *pelmènni*, a small chopped-meat pudding-tart, eaten warm; and the *caviar*, are well worthy of adoption into the English kitchen.

Amusements. The Russian is fond of dancing and music, and sings at his work the plaintive ditties of his country, in a high, falsetto key, accompanied by indescribable quavers. The women's shrill skirl is extremely unpleasant; but both sexes are mirthful, and much given to amusements, which are innocent enough, consisting of eating nuts and gingerbread of holidays, and at their carnival shows, the *Verbi*, or Feast of Palms, and the Easter festival; of gliding down ice-hills in sledges; and swinging. The *khoroòdis* are women's dances, accompanied by singing. A characteristic dance is the *kazatchòck*. Strangely enough, skating is next to unknown. The indigenous musical instruments are the *balalarka*, a sort of guitar, and the *goosli*, a sort of spinnet, now falling into disuse. Public amusements in the capi-

Statistics. tals are too dear and rare. The upper classes follow the usual European fashion. They love display; are graceful, polished, and urbane; but supple and false, not scrupulous in keeping his word, and with no manly love of exercise, the Russian nobleman is frequently one thing in public and another in private life. When the Russian noble is at the same time a gentleman, he is unsurpassed. Card-playing is the great social vice; but excessive drinking is now next to unknown. Higgling and dishonesty in trade are common in buying and selling. All classes take pride in rich furs and fine horses. Sledge-racing supplies the place of our English horse-racing, which, however, has lately been encouraged. High and low have a singular love of proverbial sayings, and all take a personal pride in the outward magnificence of the court.

Language. The Russian language, one of the most beautiful existing, is a dialect of the Slavonian, the common tongue of a large family of nations descended from the Scythians, but whose earlier origin is unascertained. If the language of a people were to be taken as an index of its destiny, a still brighter career than that already run might be augured of the country under review. In point of copiousness, flexibility, harmony, and grace, the Russian language has but few superiors, and not many equals. From the separateness of its roots, it is, however, but little assimilative; which must prevent its ever becoming so universal as English. Many of the modern roots are Sanscrit, Greek, Latin, and German. When the church-books of worship were translated, in the tenth century, into Slavonian-Russ, Greek forms, both alphabetical and of construction, were introduced, and thus was created a written church-dialect existing up to the present time, side by side with the vernacular, which it has greatly affected. The spoken language meanwhile incorporated many words from the Polish and other Slavonian dialects, the Tartar, and Mongolian; but Peter's reform of the alphabet, adoption of technical terms, and introduction into printed use of the vernacular, in lieu of the church-language, contributed the most to give the Russ that form which later culture has refined, and which it at present wears. The want of an article renders extreme precision less attainable than in those languages which possess one, otherwise than through the general sense of a phrase; but this is tolerably balanced by an avoidance of constantly-recurring particles, the great defect of the English and other languages. Adjectives, nouns, and pronouns are richly declinable in their various genders, persons, and numbers; and verbs, besides denoting in their inflections the numbers, persons, and genders, have further so-called *modes*, which clearly determine the frequent and unfrequent, the precise and unprecise modes of every action. A flexibility of construction, perhaps unsurpassed, is thus obtained; for, transpose the words as one may, sense can always be made of them. The prepositional verbs, mostly with prefixes, are a mine of wealth for the determination of action; but an insufficiency of this part of speech consists in its having but one compound tense, with *shall*, and, strictly speaking, only one past tense; through which defect a past action cannot be defined with such precision as in French. In consequence of the verb showing the gender, the personal pronouns may be dispensed with or used, at will. The great richness of the language consists, besides its inflectiveness and the copiousness of its roots, in the number of the derivatives; nouns, adjectives, and verbs, mutually giving and receiving, and all possessing this attribute to an inconceivable degree. The written character is a very neat one; and the printed has much resemblance to the Greek, some also to the Latin.

¹ It was a just retribution of Providence that visited the iniquitous tyranny in old times of Poland over Russia with eventual subjugation to the latter, not that the punishment should be eternal. It testifies, besides, historically and undeniably, to the existence of a moral principle as positively pervading the unseen as the seen world of the senses.

Statistics.

The alphabet is as nearly phonetic as can be desired, and has the advantage of expressing complex consonantal sounds, such as *ts* in *tsar*, *teh* in *child*, *sh* in *shall*, *stch* in *question*, *kh* in *ladakh*; each in one character. The Celtic guttural *kh*, the Greek χ , is the only consonantal sound in which the Russian language has the advantage, of the English; but it has not the English nasal *ng*, the *th*, the *j* as in *join*, nor the *w* as in *will*. All the vowels are neither long nor short, but properly between the two; neither have the Russians the long diph- or triph-thongal sounds of the English, as in *meed*, *mound*, and *queen*. The *a* sound in *fat* and *fall*, and the short *i* and *u*, as in *bit* and *but*, are totally wanting; whence follows that the English has several more sounds than the Russian. A set-off against this is the more frequent occurrence of liquids and of united vowel-syllables; the *a-yah*, *e-yah*, *e-ay-yah*, *e-a-u*, lending extreme harmony to the music of the rhythm. A harsh semi-vowel, which the English have not, is the quick contraction of the *oo-ee* into one sound. The most favoured letters are *p* and *r*; the ugly *s* is not so much used as in German or English; the vowels most affected are *a*, as in *far*; *yah*, and *e*. The diminutive, augmentative, and deprecativ terminations are next in expression, strength, and grace only to the Italian. Another distinctive feature of the language is, that through the peculiar inflectiveness of its nature, the purely Russian race, from the White Sea to the Black, from Poland to the farthest confines of Siberia, speak with a grammatical correctness perfectly delightful to ears that care for such niceties. There are of course vulgarisms, and here and there some slight shades of difference in the pronunciation; but they are inconsiderable indeed, when contrasted with the barbarous idioms met with in all the countries of Europe. The Little Russian is certainly a marked deviation from the rule, but this is not the pure Russian race. Russ is spoken most elegantly in Moscow and Petersburg. The points of beauty in this language are so striking that much might be taken from it as first principles for a universal language, were any such possible; and an unbeliever in the great advantages derivable from these varied inflections would best be convinced by contrasting the cumbrous phraseology of an English law document with that of a Russian one. There is little intonation of whole phrases—raising or sinking of the voice—compared to English, the most intoned of living languages, and which is a remedy for its large number of monosyllabic words. Russian words, on the contrary, are egregiously long, in proportion to the graduated short words; a result of which is, that one page of Russian print, despite the saving of particles and repetitions incident to the varied inflections of the Russ, would make on an average no more than three-fourths of an English page. There are, however, much fewer ellipses in Russ than in English, the most elliptical language spoken; and this is partly another cause of English concision. For poetry, the language is beauty itself, being hard and soft in due proportion; and it admits of all rhythmical measures, besides affording every imaginable facility for rhyme. And it was for nasal French that the upper class of Russians could abandon their own far more beautiful tongue! What can not fashion in its folly do?

Mythology.

The Russian mythology is common to that of the whole Slavonian race. Their thunder god Peroñ answers to the Greek Zeus, or the German Wodan. His statue stood, in times of old, in the yard of Vladeimir's court at Keeyeff, and was of wood, with a silver head and gold moustache. The annalist Nestor (1060) makes mention of the gods Kors, Dàshbog, the god of fruitfulness (*boy* signifies *god*), Shreebog, called also Samergl, and Mòkosh. The name of Vòloss, denoting hairiness, occurs in the Grand-Prince Oleg's conversations with the Greeks, as the protector of

herds, and it was by his and Peroñ's name that the Russians confirmed their sayings by oath. The goddess of love, friendship, and unity, was Tada; lovers and the newly-married sacrificed to her, praising her name in songs. Her sons Lelia and Palelia were also honoured as the gods of love and marriage. Kupàlo was the name of the god of harvests, and sacrifices were made to him before harvest, on the 23d of June; this festival was called the Kupalaizta. Young people decked themselves with flowers, lit fires in the evening, danced round them, and sang in honour of the god. The memory of this feast may still be traced in the fires lit to this day on St John's Eve. In the government of Arkhangel, many of the peasants still heat their baths on the 23d of June, strew their floors with *kupalinka* (*Ranunculus acris*), and then bathe. The root of the word implies bathing. Deèvo was the name of the Evil One. The 24th of December was holy to the god of peace, Kolèda; the rejoicings of Christmas Eve, consulting the future, and the custom called Koledovànie, now existing in Little Russia, are living remnants of this festival. Forest-demons, house-spectres, and good spirits were also supposed to exist. The Roossàlka, a naad, though no more seen, is still believed in; and the ancient Russians further venerated trees, particularly hollow ones, and bound linen cloths round their branches. They had temples and priests; they burned their dead, and held feasts in their honour.

Statistics.

Briefly outlined, Russian literature has undergone three Literature.

marked changes: 1. The literature developed under Greek influence by the introduction of Christianity, 988–1689; 2. That first improved by Peter the Great on the general European model, from 1689–1801; 3. And the more polished, lasting from Alexander I. till the present time. The first period is long as regards duration, but poor as regards matter. Tales and songs, mostly oral; chronicles, and spiritual books describing the miraculous doings of the saints, reviling the Latins, or disputing about the sectarian heresies, were its chief products. The subsequent invasion of the Tartars, 1238–1480, not only checked the advance of civilization, but threw it back by many centuries; and during this period the learned sought refuge in the cloisters. The incorporation with Russia, in the sixteenth century, of the grand principality of Lithuania, naturally operated on the letters, such as they were, of the country, by introducing the more advanced literature of Poland. John IV. established the first printing-office at Moscow in 1564. Dramatic art dawned late. It was in the seventeenth century that the students of the Keeyeff academy began to perform religious mysteries in Polish and Slavonian; and under the tsar Alexay Mikhàilovitch, 1645–1676, the boyar Matvayeff invited German actors to Moscow, where they performed pieces, with music and singing. Throughout this period, but no later, the whole literature of the country was in the hands of the clergy, who were thus the centre of the refinement that existed. The second period is marked by Russia arousing from her intellectual stupor. Peter had appeared; and from this time the country enters within the pale of European civilization. He invited learned foreigners to his dominions; sent young Russians to Germany and Holland for the acquirement of useful learning; and such was the impulse he gave, that in a few years Russia made more progress in civilization than in many preceding centuries. Relations had indeed been maintained with Europe under John III., but their influence had been unfelt. It was under Peter, too, that the first newspaper—*The St Petersburg Gazette*—was issued, in 1703. It contains matter very interesting for the present age. Peter's own time was not marked by any distinguished writers; but most of the successive sovereigns only executed what he had originally conceived and planned. Lomonosoff, the son of an Arkhangel fisherman, a learned prosaist, although an indifferent poet, under Elizabeth Petrovna, was the earliest

Statistics.

classical writer of his country, and the great practical reformer of her letters. He first introduced *measure*, in lieu of the pre-existing Polish *quantity*. Kantemir, Soomardkoff, Kniaznèen, and Kheràskoff are names of secondary note, intervening between this time and Catherine's more glorious epoch. Derzàvin, the first great poet of his country, and who flourished in her reign, stands higher than all before and after him until the appearance of Pooshkin and Lermontoff. His *Ode to God* has been translated into English by Bowring, whose *Anthology*, containing specimens of the Russian poets, is deserving of commendatory notice. Von Wisin, the successor of Kantemir as a satirist, still retains possession of the stage. His comedy of the *Spoiled Minor* would alone throw more light on the manners and customs of his country than many books of history. This second period, although unmarked by many gifted writers, was still rich in translations from the ancients, French literature, and works of science, which circumstance had a vast influence upon the mental refinement of the people. There even existed under Catherine II. a department for translations. In this respect the country owes much to Novikoff, who, under Catherine II., founded the Literary Society of Moscow, the precursor of the Academy of Sciences, and devoted his whole life and fortune to this object. The earliest illustration of the third period is Karamzin, who, as a prosaist, first broke through the rules of ancient classicism, and introduced the romantic school. He is best known as the historian of his country, although his fame as such now suffers diminution; but his style is still deservedly celebrated for its purity, and he has been followed by Oostriàloff and Solovioff. In universal history, Grandffski and Koodriàvtseff are the best representatives of Ranke's school. Dmeetrieff is a fable-writer of merit; but Kreeloff's fables, for point, satire, raciness of style, and adaptation to life in his country, are equal to those of any age or land. The best tragic dramatist is Ozeroff, but he is pompous, and writes too much in the French style. Greeboyedoff's comedy of *Sorrow Comes of Sense*, a social satire on Moscow society, may be classed with Beaumarchais' *Marriage of Figaro*, or Sheridan's *School for Scandal*. Gogol's *Revisor* is a satire of like eminence, on the corruption of his time. The only other dramatists of distinction are Pooshkin, and Ostròvski, a contemporary author. The Russian drama was originally formed on the declamatory French model; but Shakspeare has long beaten French tragedy off the stage. For vaudevilles the French style still prevails, because the best. Independently of the earliest national poetry, of which numerous collections have been made, and not to dwell here on the claims, as poets, of Bogdanovitch, Khèmnitzer, Bàtiushkoff, Kozloff, Countess Rostoptchin, and others, all of more or less distinction, the names of Pooshkin and Lermontoff speak for themselves as the greatest. Pooshkin, in particular, is the poet of his country, from his identification with the national mode of feeling. His prose is a model of polite style. The living poets of mark are Maikoff, Tiutcheff, Nekràssoff, and Stcherbina. It is remarked of Russian poetry, two-thirds of which is imitative, that, with much melody of versification, it has but little substance. More tender than impassioned, more graceful than energetic, the unseen spirit of song rather glides over the surface of feeling than issues from poetry's true home, the well of passion, lying deep within the heart. Russia is a land of song, and numerous collections therefore exist of national, Little Russian, Finnish, Lettish, and other songs, well meriting attention. The first novel was written by Kheràskoff, under Catherine II., not that it was a good one; but of the later novelists and belletrists, the oldest are Lazèchnikoff and Zagòskin; then follows the inimitable Gogol; and afterwards come Peèsemski and Gontcharoff. Pooshkin, Kookolnik, Count Sòlohub, Greegorovitch, Count

Asiatic Russia.

Tolstoi, and Toorghènieff, the last and best, are delightful story-tellers. Translation, which now supplies the place of civilizers from abroad, is cultivated in every branch to an immense extent. A remarkable production in this art was Gnèditch's translation of the *Iliad*, which, though heavy, is still correct. It was from 1820 to 1840 that translations began chiefly to be made from the German. Zookoffski, in particular, gave the impulse to translations from that language and from English. The most distinguished in this department, not to speak of purely scientific works, are Bàtinshkoff and Zookoffski. The other names are Kozloff, Huber, Vròntchenko, Kronberg, and Min. Ketcher is a very accurate translator. Most of Shakspeare's plays, and indeed many of the best English productions in verse, including several of Byron's poems, have been beautifully done into Russ; besides numerous translations from the ancient and living languages. In philology, the chief names are Booslàieff, Sjogrén, Castrén, Schiffner, Wiedemann, Bòthlingk, Dorn, Pavski, Vostòkoff, Gretch, Kasembeg, and Davidoff. Statistics, including finance and political economy, have lately made immense progress. We need only allude to Arsènieff, Koppen, Tengobolski, Nebolsin, and Lamànski. In medical surgery, Peerogoff is known to all Europe. Philosophy is yet a barren field, and many departments of letters are still unrepresented; but in the higher walks of science it is sufficient to cite Pallas, Frèhn, W. Struve, Bar, Ostrogradski, Kupffer, Jacobi, Pander, Abich, and Vesseloffski. The fine arts have had, and still have, distinguished disciples in Kokòrin, Marthus, Count Theodore Tolstoi, Baron Klodt, Bruloff, Bruni, Basen, and Evànoff. Bortnianski's church music is abstract beauty tangibly revealed to the senses. As travellers and navigators, we have Golovnin, Kotzebue, Krusenstern, Bellingshausen, Lütke, Wrangel, Tchikatchoff, Yermòloff, Demidoff, Middendorff, and Kovalèffski. The church literature is perhaps the most popular and widely diffused. Platòn, Innocent, and Philarèt are the most eminent sermonists. Prokopovitch, Yavòrski, Philarèt of Moscow, Philarèt of Kharkoff, and Macarius, are eminent as theologians. Periodical literature has made immense strides, and at present absorbs nearly all the intellect of the country. Belinski, as a critic, exercised over it a lasting influence. Herzen's *Kòlokol*, or *Bell*, and his *Northern Star*, both published in London, form a remarkable feature in the journalism of the day. An encyclopædical lexicon is being published by Kraieffski; and a movement has been made towards furthering the introduction of the decimal system. Generally, it may be truly said that purely intellectual civilization has lately advanced with the step of a giant. That Russian literature has not yet contributed its full quota to the great hive of human learning should be mainly ascribed to over-government, to its being yet in the youth of its existence, and still in a condition which compels it to borrow much. When civilization shall have taken firm root in all classes, then Russia will no doubt enlarge her pretensions; but the time is coming, and the minds to do the work are ripening.

Asiatic Russia.

Russia in Asia comprehends the whole northern portion of that continent extending from Lat. 38. 25. to 78. 26. N., and from Long. 37. 14. to 190. 22. E. from Greenwich. It is bounded on the west by European Russia and the Black Sea, on the south by Asiatic Turkey, Persia, the Caspian and Aral Seas, the territories of the Turkomans and Keergheez, and by China; on the east by the Pacific Ocean and Behring's Straits. The Frozen Ocean extends along the whole of its northern limits. Its greatest extent from west to east is about 4142, and its greatest breadth from north to south 2622 English miles. This vast dominion

Asiatic
Russia.
General
aspect.

is larger than the whole of Europe. Siberia, which occupies the whole north of Asia, from the Ooral Mountains to the Great Ocean, has a general inclination towards the Northern Arctic Sea. It presents an immense plain, bounded on the south by ranges of mountains. In the northern part this plain gradually inclines into a low flat. Siberia is divided by the Yenisey into two regions, the western and eastern. Western Siberia is one entire level, unbroken by any hills whatever. The north-western region is covered by forests; the other part consists of steppes. 1. The Barabinskaiâ steppe, between the rivers Irtysh and Ob, has large birch groves, and is suited to agricultural pursuits. 2. The Ishim, to the south of Omsk, along the rivers Irtysh and Ishim, consists of sands and salt-marshes. 3. The Kheergheez steppes, extending from the left of the River Ooral to the Caspian and Aral seas, form a wilderness whose eastern and north-eastern parts alone are intersected by hills, forming a continuation of the centre chain of the southern Ooral. The soil consists of clay and sand, but in the south-west it is overspread with salt-marshes and bogs. 4. The Abakan steppes lie along the River Abakan, which falls into the Yenisey. Their soil is so fertile that it requires no manure. 5. The Sagai, lying between the left bank of the Abakan and Lake Teletski, and extending in the north to the River Tchoulim, serve as excellent pasture-grounds for the countless herds possessed by the natives. Eastern Siberia affords a much more diversified aspect. The plains are here intersected by numerous offshoots of the high Altai and Sagan mountains, as well as by the Yablonnoy and Stanovoy ranges. The northern Siberian flat, from the Northern Arctic Circle to the Polar Ocean, and from the Ooral Mountains to Behring's Straits, may be divided into three portions. The first, from the Oorals to the Yenisey, does not rise above the level of the sea; the second, from the Yenisey to the Lena, is a little above that level; and along it, from south to north, extends the Poostinnoy range of hills, which, terminating in Cape Severo-Vostotchnoi, serves as the dividing water-shed of the Yenisey and Lena. The third portion, from the Lena to Behring's Straits, is considerably higher than the water-level; and more eastwards it is intersected by branches of the Stanovoy Mountains, which never reach above 3000 feet. The whole of this flat has a dreary character, and the magnificent forests which cover the whole south of Siberia become gradually thinner. At 70 N. Lat. all vegetation ceases, and nature seems as if deprived of life. The soil of this northern Siberian flat is one continued moss-grown tundra.

Mountains.

The Siberian mountains extend from the River Irtysh at first eastwards to the upper sources of the Aldan, which falls into the Lena, and hence through Kamtchatka towards the north-east. They terminate in two branches, of which one extremity is called Tchoukôtskoi Noss, and the other Cape Lopâtka. That part of the Siberian mountains which passes from west to east consists of the Altai, Sayan, and Daoorian chains. The Altai sweeps along the southern confines of the governments of Tobolsk and Tomsk, and, by means of the Yablonnoy and Stanovoy ridges, unites in the north-east with the Okhotsk Mountains. This Altai range is 450 miles long and 230 miles broad, having numerous offshoots. Its general height is 7000 feet; but the pinnacle of one, called the Beldokha, attains the height of 12,000 feet. The snow-line is from 6000 to 6500 feet above the horizon of the water. The Altai serves as the dividing-line from which flow the rivers of that region, on one side into the Arctic Ocean, and on the other into the streams of the Keergheez, Turkestan, and Zoonghôi steppes. The Sayan mountains extend betwixt the Yenisey and Baikal, a distance of 1260 versts. The Daoorian extend from the Sayan mountains,

touch the Yablonnoy range, and run into the Chinese dominions.

Asiatic
Russia.

Rivers.

The rivers of Asiatic Russia that discharge themselves into the Arctic Sea are amongst the most considerable of the ancient world. The most remarkable of these are,—1st, The Ob, whose course is 2170 miles in length, during which it receives the great rivers Tom, Tcholeem, Ket, Vakh, the Irtysh, Sosva, and all their tributary streams. 2d, The Yenisey, which has a course of 2000 miles, with fewer sinuosities than are usually observed in other great rivers. It is formed by the confluence of the Great Ket and Angarâ, which latter is the greater river of the two. The upper Toongoozka or Angarâ rises in the government of Irkootsk, joins the Eeleem, and flows for 1000 miles. The right affluents are the Middle and Lower Toongoozkas, and the left are the Abakan and Toorookhan. 3d, The Lena, one of the largest of the Russian-Asiatic rivers. It rises in the Baikal Mountains, in the government of Irkootsk; is from half a mile to 2 miles broad, at Irkootsk about 6 miles; and falls into the ocean in Lat. 70. 40., and Long. 164. 26., after a course of 2666 miles. The Lena is navigable at Verkholsensk, 200 miles from its source, until it receives the Aldan. Its tributaries on the right are the Vetcem, Olekma, and Aldan; on the left the Velui. Besides the Ob, Yenisey, and Lena, whose lower courses water the northern flat of Siberia, along the tundras flow the following considerable rivers:—The Taz, Khatanga, Anabara, Olenek, Yan, Indighinka, and Koleema. The rivers flowing from the eastern declivity of the Stanovoy hills into the great ocean and sea of Okhotsk are mostly unimportant and rapid, because this range is steep, rocky, and often closely approaches the shores. The chief are the Anadir, Kamtchatka, and Avatcha, remarkable as forming the bay of Avatcha, surrounded on all sides by mountains, and 9 miles in diameter; Port Peter and Paul, the Penzzena, Gizeeghina, Okhôtâ, and Amoor.

The Amoor is formed by the confluence of the Argoon Amoor and Sheelka, in the south-east angle of the Trans-Baikal River. region, at a point called the Oost-Strelka. The Trans-Baikal region spoken of borders on Chinese Daooria, of which latter a vast portion has been silently incorporated with Russia, and called Russian Daooria. From the Strelka mouth to the last Russian station on the Tartar Gulf, called the Petrofskoië Winter Quarters, the entire length of the Amoor is 1880 miles. The chief tributaries of this river are the Zayâh, Newman, Amgoon, Soongari-Oollah, and the Oossoori,—all mighty streams. The Soongari-Oollah, called in Chinese Khoon-Taon-Tsian, unites with the Amoor 950 miles below the Strelka mouth. The Soongari runs through Chinese Mantchooria, and the Amoor may rather be said to fall into it. In many places from a mile to a mile and a half broad, the Amoor is navigable throughout its whole course, the depth being considerable, often averaging ten fathoms; and there are few rapids or shallows to impede navigation. It must, however, be observed, that the last exploring expedition took place in May, when the waters were at their highest. The current generally runs at the rate of 2½ miles an hour. No forts are as yet laid down along the river's course, and it is only near the mouth of the Amoor that there are fortifications; but they have not yet had time to become important. The left river-bank is being permanently colonized. The sole considerable position at present held by the Russians on the right bank is the Mareeinski station, near Lake Keezi. Sakhalen-Oollah-Khotôn is the only large town on the Mantchoorian or right bank of the Amoor. On the left bank there is not a single town. Toongooz tribes inhabit the whole of this region, which is extremely fertile, the soil and climate being both excellent.¹

¹ The rapid extension of the Russian empire at present taking place in this region, and the political results that are likely to ensue

Asiatic
Russia.

Lake Keezi, at the Mareeinski station, on the right bank of the Amoor, is 26 miles long, of varying breadth, and in parts tolerably deep. It naturally forms a convenient harbour, and the idea has therefore been entertained of establishing a way of communication, either by canal or rail, across the hilly ridge—only 13 miles in breadth—which separates Lake Keezi from De Castries' Gulf in the Sea of Okhotsk. When one takes into account that the Mareeinski station is 290 miles higher up the river than its mouth, the utility of the plan becomes obvious. A railway from the Amoor, to be connected with the internal lines of road, has been more than once projected; but either the demands made for a cession of bordering crown-lands were so unreasonably exorbitant, or the offers made so unsupported by sufficient guarantees, that the plan has been rejected. The railroad will yet be effected, though on another basis, and then the results will be of high interest to England. The chief considerations which suggest themselves are,—1st, That Russia has now managed to acquire a vast portion of Chinese territory, with a valuable harbourage and sea-board, on the North Pacific; 2d, That a vast amount of trade in Central Asia is being opened out to her merchants: and, 3d, That she is hereby obtaining a direct water communication with India, which is thus in process of becoming more and more closely hugged by Russia both by land and sea. Two rivers, of great interest to England, remain yet to be noticed: the Oxus, or Amoo-Daria, which rises in the western extremity of Lake Sir-i-Kol, Lat. 37. 27., and chron. Long 69. east of Greenwich, in the table-land of Pamir in Central Asia; and the Jaxartes, or Sir-Daria, which rises in China, and passes through Kokan, Turkestan, and Tashkent. Both fall into the Aral Lake, the Amoo-Daria, after an approximative course of 800, and the Sir-Daria of about 520 miles.

Lakes.

The lakes in Russian Asia are very numerous, and some of them so extensive as to form inland seas. One of the largest is the Baikal or Holy Lake, between Lat. 52. and 55., and Long. 104. 26. and 109. 56., extending over 11,180 square miles. Its water is clear and bright, and the depth varies from 18 to 500 feet. The River Angara, which runs into the Yenisey, issues hence. It contains a great number of rocky islands. The other is the Aral Lake, or Blue Sea, situated on a parallel with the northern part of the Caspian. It is 250 miles long by 150 miles broad. The lakes next in extent are the Tchani and the Piasenskoe, both in the government of Tomsk; but there are one or more lakes in every province. A large number of steamers already ply on these inland seas and rivers of Asiatic Russia.

Climate
and pro-
ductions.

From the Ooral Mountains to the Yenisey the climate differs little from that of European Russia, but beyond that river the difference is marked. The general severity, however, of the climate in Russia—apparently so inimical to health and comfort—is considered by the inhabitants as one of their greatest blessings. The vast expanse of frozen snow that environs them both shortens distances and facilitates travelling. Ice-cellars also form a positive necessary of life, for by their means provisions, which could not otherwise be kept from putrefaction, are preserved during summer. The fine fresh air engendered by a bracing

Asiatic
Russia.

frost is likewise most conducive to health. The intense cold, however, that prevails in Siberia beyond the Yenisey, like every extreme, is an evil, and forms one of the great obstructions to travelling, as does also the plague of mosquitoes in summer. The natural wealth of the country consists at present in its minerals, timber, furs, produce of the chase, fisheries, and cattle. The southern territory, which is often covered with luxuriant pastures, might be made to yield very rich crops, if the inhabitants would but change their taste for nomadic life, and till the ground. For some time past, indeed, the Kheergheez have shown indications of commencing agricultural pursuits; yet notwithstanding the general neglect of tillage, the produce is in some parts extremely plentiful, and crops are raised even without the aid of manure. The rearing of sheep for wool is a branch of industry lately much increased in Siberia, and the Kheergheez steppes supply countless droves of cattle for the Russian market. Pasturage, indeed, and agriculture will ultimately form the chief riches of the land, because inexhaustible. The mineral productions are gold, silver, lead, platina, copper, dendritic and stalactitic copper or malachite, iron, coal, anthracite, tin, cinnabar, and zinc; bismuth, arsenic, sulphur, alum, sal-ammoniac, nitre, naphtha, and natron, are met with in abundance; and a few precious stones are also found. Near the River Argoon are found the common topaz, the hyacinth, the Siberian emerald, the beryl, onyx, and beautiful red and green jaspers. Near Yekaterinburg are the gem-mines of Moorsinsk, where are found the beryl and chrysolite. Near Lake Baikal red garnets are very common; and *lapis lazuli*, as well as the baikalite of Keervan, are also met with. The Altai Mountains furnish the opal.

The mineral springs of Russia are found principally in the Asiatic part, especially in Kamtchatka. The only European mineral waters that merit particular notice are the hot spring near Selo-Klitchy in Perm; a chalybeate spring in the village of Singovo, Olonetz; an assemblage of springs strongly impregnated with iron near Sarepta, on the Volga; the Sergius sulphur waters in the government of Orenburg; several naphtha springs in the Taurida; and at Piatigorsk, on the Terek in the Caucasus, warm springs, that serve as baths. Similar baths exist in the province of Nertchinsk, and springs impregnated with naphtha and petroleum are also found near Lake Baikal. Chalybeate waters likewise are met with among the iron mines near Yekaterinburg, and a few in the province of Daوريا. The principal hot baths of Asiatic Russia are in Kamtchatka. Those near Natchikhin, containing vitriolic and nitrous salts, fall in a rapid cascade, about 300 feet below which they are collected into a basin 6 or 7 feet broad, and 18 inches deep.

The territory which stretches along the southern Asiatic Frontiers, border alone deserves particular mention, as the most favoured district of Siberia. This vast space is chiefly inhabited by Kozzacks, whose number has been lately much augmented, under a system perfected between the years 1852-59 by Count Mooravieff-Amoorski. There are three descriptions of Kozzacks—the inhabitants of towns, foot regiments, and horse Kozzacks, who form the chief military

therefrom, warrant us in here giving a short account of the Amoor acquisition. It was in 1845 that Academician Middendorff, appreciating the necessity of an outlet for Siberia into the North Pacific, crossed the frontier despite Chinese prohibition, and found during his four months' travels in this quarter, that the Russian government erroneously considered the Stanovoi mountains as their boundary by the treaty of Nertchinsk, the Chinese themselves having erected boundary-posts much more southerly, among the left affluents of the Amoor; and that thus an immense extent of territory would accrue to Russia, besides the desired outlet into the Pacific. About the same time Captain Nevelskoi, after sailing round South America, entered unbidden the mouth of the Amoor, being the first European navigator who had ever done so, and proved that Sakhalin was not a peninsula, but an island. Delighted with the discovery communicated to him by Academician Middendorff, Nicholas immediately acted upon it. Captain Achte was despatched to execute the idea, and political circumstances being favourable, the result has at length been the acquisition by Russia of the whole left bank of the Amoor, its right and left banks from the Osoori downwards, the dependent sea-board on the Gulf of Tartary, its outlet into the Pacific, its prospectively boundless trade, the whole island of Sakhalin, and nearly one million square miles of territory. Russia now wants only an outlet into the North Atlantic by the acquisition of a seaport in Swedish Finmark.

Asiatic
Russia.

arm of the country. In their capacity of soldiers, they mount guard in turn at the different posts assigned them; and their leisure time is employed in the rearing of cattle, gardening, hunting, and fishing. The territory they occupy is for the most part very fertile, especially between the forty-ninth and fifty-first degrees of latitude, where the soil spontaneously produces fruit trees, melons, tobacco, &c.; whilst in the most easterly part the picturesque and fruitful valleys of the Altai, rich in every description of odoriferous flowers, enable the inhabitants to rear innumerable swarms of bees, which furnish the greater part of Siberian honey. Several manufactories, especially of leather, have been established in the towns. The progress of trade will doubtless hereafter enhance the value of the natural productions of these regions, amongst which must be reckoned the lakes of salt water so numerous in the steppes. Important as they are in relation to commerce, these lakes likewise present to the naturalist a series of interesting phenomena. Their waters hold so great a quantity of salt in solution that the action of the summer heat is of itself sufficient to convert it into crystals, which, carried towards the banks, form there immense shoals of salt. Magazines have been formed upon the borders of Lake Koriak, and the salt therein preserved generally amounts to many thousands of tons. But however rich this lake may be, it is less so than three others, the Karoshak, the Kolkaman, and the Djémanton, situated in the steppes on the right bank of the Irtysh. Each of these basins is from 12 to 15 miles in circumference, and the action of the solar rays produces in them during the summer season crystals of salt so numerous that, by mutual contact, they at length form solid arches, which, like winter ice, cover the surface of the lakes. These masses are frequently nine inches thick. The action of the air whitens the upper layers; the lower ones preserve a bluish tint, which in some places assumes a beautiful violet hue; and the solidity of these crystal fields is such that horses, camels, and chariots pass over them with the greatest safety.

Mines.

The mines of Russian Asia are by far more productive than those of any other portion of the empire, as from them is extracted the whole of the gold, silver, platina, and lead, nine-tenths of the copper, and eleven-twelfths of the iron which is brought into use. These mines are mostly situated in the Ooral and Altai mountain ranges. It is in those parts which face Siberia—that is, the eastern slope of the Ooral, and the northern declivities of the Altai, with its secondary branches—that are found the veins of precious metal. The best account of these mines is that contained in Tcheyffkin's able work on the subject, published in 1851, and to which we call particular attention, as well worthy of translation. The original discovery of gold—and that, too, in its native state of veins—occurred in 1743, near Yekaterinburg; but the subsequent discovery, in 1814, of auriferous sand-fields afforded a much cheaper means of obtaining this metal, and caused the working of gold-mines to be nearly abandoned. The Berezzoff mine gold, containing $1\frac{1}{2}$ oz. troy to 100 cwt. of ore, cost, for working expenses alone, 18s. an oz.; whereas the sand-gold of the same mining district, containing only $\frac{1}{2}$ oz. in 100 cwt. of sand, cost but 10s.; so that, supposing the yield to be equal, the extraction of sand-gold would be ten times cheaper than that of ore-gold. The working of auriferous sand-fields was first introduced by the Ooral government mining foundries; but in 1819 it passed into the possession of private foundries. In 1829 private companies began to work these fields in Western, and about 1838 in Eastern Siberia. An extension of the gold produce in Russia is scarcely to be expected. For several years no new discoveries of importance have been made, excepting only in the Nertchinsk foundry district, where, indeed, such promising deposits have been found among the affluents of the

Sheelka that the yield of this district, which amounted from 1846 till 1849, to about 8 cwt. a year, rose in 1850 to 24 cwt. The love of exploitation, however, has subsided; the former deposits are becoming exhausted; the yield of the auriferous sands is perceptibly diminishing; and the gain of the private Siberian companies, particularly of Eastern Siberia, has sensibly decreased. The average yield of the sands washed in the Oorals, which, from 1814 to 1839, was 12 dwt. of gold to 100 cwt. of sand, fell in 1846 to less than 5 dwt.; and there are whole districts where the yield of the sands has fallen to below 4 dwt. In the Verkh-Issetski foundries of Mr Yakovlieff, for many years, about 50 cwt. of ore are won, at a yield of only 2 dwt. With regard to diamonds, only small stones are found. These regions, as yet but little known, are now explored with systematic regularity. The two chains, the Ooral and the Altai, are divided into several mining districts. In each of them, the officers to whom is confided the direction of the works send out every summer detachments of discovery, whose duty it is to examine in detail the mountains assigned to them; and the point at which the expedition stopped the preceding year is generally that of departure for the next year's expedition.

Asiatic
Russia.

Asiatic Russia, independently of Transcaucasia, has recently been distributed into the following divisions:—
Western Siberia, comprising the governments of Tobolsk and Tomsk, and the provinces of Semipalatinsk and Omsk; Eastern Siberia, comprising the governments of Yakootsk, Yenisey, and Irkootsk, and the Transbaikal and Kamtchatka provinces. It is further intended to divide the Amoor region into two new provinces.

Divisions.

The population of this territory amounts to 5,361,234 inhabitants, and consists of Slavonians, called Siberiaks, settlers from the interior of Russia; Siberian Kozzacks, Finnish races, Samoyeds, Ostiaks, Toongooz, Yakoots, Booriats, Gheeliaks, Mongols, Tartars, and Keergheez. It is rapidly increasing; and here, as in the Caucasus, it was religious questions, much more than political causes, which contributed most to the colonization of the country. In 1765 alone, 40,000 sectarians, called Polish settlers, were exiled to Siberia from Starodoub and other towns in the government of Tchernegeoff; and fully two-thirds of the Ooral Kozzacks are also sectarians, whose superstitions are extremely absurd, and often noxious. In ten years, from 1832–42, seventy thousand peasants, male and female, were sent to Siberia for bad conduct by their proprietors, the town corporations, and rural communes. Except for crimes, however, none can be sent without their families. The Swedish officers who fell into the hands of Peter the Great, and a regular succession of recruits furnished by the empire itself, formed another part of the population. The lowest class of exiles are condemned to the mines; a class whose offences are of a milder character, are distributed amongst the distilleries; a third class receive grants of lands, for which a trifle is paid to government. The individuals comprising this section are formed into settlements, under the superintendence of a strict police. Siberia has its schools, gymnasia, and other institutions of the kind, which have lately been much increased. Irkootsk is the centre of the greatest civilization, and it possesses a section of the Russian Geographical Society, very important for statistics. The Keergheez steppes are supposed to contain about 750,000 inhabitants, divided into the Great, Middle, and Little Ordes.

The manufactures are few, and unimportant, with the exception of spirits and leather, which are made to a considerable extent in various parts. There are several establishments for soap-boiling, the melting of tallow, and making of stearine candles. Cotton and wool are manufactured in some parts into coarse stuffs. The chief trading towns are Irkootsk, Kiakhta, Krasnoyarsk, Omsk, Tomsk, and

Manufac-
tures and
commerce.

Asiatic
Russia.

Tobolsk. Irkootsk, the principal city of Eastern, and Omsk, of Western Siberia, being the seats of the respective governors, are of course emporiums for the sale of European commodities, which are also largely dealt in at the fairs of Ibit and Tiumen. This latter place is rapidly rising in importance. Independently of the sale of colonial and other goods, the produce of European Russia, such as corn, meal, and iron, tools and utensils, are exchanged for the skins, cattle, caviar, fish (salted and fresh), and game, brought to them from the interior by the Ostiaks or Tartars. Every year the merchants of Tobolsk, Tiumen, and other towns send boats laden with flour up the Irtysh and Ob to Berezhoff and other small towns situated farther to the north, and these boats return freighted with fish. It is, however, on the Caspian that the most productive fisheries are established. One alone is farmed for L.34,375 yearly, and there are several others; but, like its waters, the productiveness of this sea is declining. Measures have been proposed to remedy this evil by piscicultural enactments. The Oural river yields also great quantities of *belooga*, or large sturgeon, which furnishes the delicate Russian caviar. The agents of the merchants, established in the small towns upon the banks of the Ob, purchase also of the Ostiaks valuable furs, which, together with soap, tallow, and leather, they afterwards export, partly to the fair of Neezni-Novgorod, and partly to the Keergheez of the steppes, who pay them in horses, cattle, and cotton stuffs, purchased by themselves of the Bookharians; the remaining produce of the government of Tobolsk is exported by the way of Kiakhta into China, whence are brought in exchange silks and tea. Kiakhta is the sole point of commercial intercourse between the two great empires of Russia and China. Almost all the principal tea-dealers in Russia have agents at that place, whilst the Chinese traffickers consist chiefly of temporary visitors without their families. The Russians there receive the staples of China, for which they give in return the productions of their own country. The nature and extent of the commerce of Kiakhta will be seen from the following statement:—

There is a school at Kiakhta for teaching the Chinese language. The trade with China is a great source of wealth to Siberia, as will also be that carried on by the Amoor; for now that Siberia has an outlet on the navigable Pacific, it will flourish like California.

Another great commercial line is that which branches from Irkootsk, down the Lena, into the heart of the frozen regions and the shores of the Arctic Ocean. Yakootsk, situated about 800 miles down the Lena, is the emporium where the furs and other products of these desolate regions are collected. They are brought from the remotest extremities of the land which borders on Behring's Straits, and from the American territory. A considerable proportion consists of the tribute which is paid to government, and the wandering traders exchange tobacco, spirits, cutlery, beads, and toys for the remainder. The wild animals of this country are the polar bear, wolf, lynx, Arctic fox, wild boar, beaver, sable, ermine, squirrel, sea-lion, walrus, seal, otter, and sea-cat. Stray tigers and panthers have likewise been met with.

A geographical and statistical account of the Caucasus at large having been already given in the general description of Russia, we need only add the following complementary remarks. That part which extends from the southern governments of European Russia up to the central mountain range of the Caucasus belongs to Europe, and is called Ciscaucasia; the part beyond belongs to Asia, and is called Transcaucasia. The latter is divided into the following governments:—1. Tiflis; 2. Derbend; 3. Tchekmakha; 4. Erivan; 5. Kutais,—each with a chief town of the same name. Tiflis is the capital. These governments comprise the former provinces of Gruzia, Armenia, Imeritia, Daghestan, and some other lesser ones. Small as this territory is, compared with the vast extent of Russia, it is of no trifling importance to her in a commercial, financial, and political point of view. Its geographical position appears to us the happiest possible for a power prosecuting gigantic schemes of commercial intercourse and of territorial aggrandizement. Climate, soil, natural capabilities, situation, and political relations, all prove that, whatever it has cost Russia to acquire and maintain her Transcaucasian dominions, their value, which as yet is developed only to a small extent, justifies her policy. A history of the Caucasus, with a full account of its productions, by Colonel Usar, being about to appear under the auspices of the Russian government, we would rather call attention to this fresh source of trustworthy information than give returns which are both incomplete and antiquated. The following general account we know to be true:—

The cultivation of the mulberry tree is now very much improving, and as much as 9660 cwt. of raw silk were forwarded in 1858 to Moscow alone for manufacture there. Silk.

The natural capabilities of the country afford a possibility of immensely increasing the production of this valuable commodity. It has lately been very much developed. The quality is still rather inferior; and although cotton is produced in some of the other southern or Asiatic possessions, it will be long ere Russia becomes independent of the United States for this article, more particularly since her own internal demands are extensively increasing. Cotton.

The wine is indigenous to these regions, and presents a great variety of kinds. The vineyards are numerous and rich, the country being well adapted for the cultivation of the plant. All the wine and brandy produced are entirely absorbed by the internal consumption, which is incredible. Among the natural products likely to become important articles of trade, but which are at present nearly all consumed at home, are rice, saffron, madder, and cochineal. The Armenian or southern parts of the Transcaucasian provinces, produce a kind of cochineal which is said to yield a dye equal to that of Mexico. The mountain off- Wine.

Asiatic
Russia.Transcau-
casia.

Asiatic
Russia.

shoots of the Kazbeck and Elbrooz are rich in silver-lead ore, which has been found in fifty different places. Parts of this country also produce coal.

Live stock.

Extensive herds might be reared in these provinces, which afford great facilities for their maintenance. Great numbers of cattle and sheep are indeed raised, but the wool of the one is bad and the breed of the other inferior. Merino sheep have been successfully introduced into this quarter. There is a fine race of horses, and an abundance of camels, asses, mules, and swine. The natural capabilities of these provinces are very great, affording facilities for the production of the most valuable commodities, exclusively furnished by southern climates. These have only been developed to a partial extent; but the government displays so much laudable zeal in encouraging such branches of industry as are best suited to the various divisions of the empire that, after a certain time, she will be nearly independent of what are called colonial goods,—silk, cotton, and the like.

This is not the place to enter into the important question relative to the political influence which Russia is likely to exercise over the East by thus firmly establishing her dominion beyond the Caucasus; but her far-sighted policy has two main objects, which will be promoted by rendering the Caucasian isthmus a commercial country, securely incorporated with the rest of the empire. These are the creation of a manufacturing industry that will in time render her independent of other countries, particularly of England, and the establishment of her power in Asia, whence great advantages are not unreasonably expected. Now these provinces will at once supply the raw material necessary for manufactures, and at the same time open out a market for them in the East. It is true that the Caucasian mountains almost totally sever this limb from the great body of the empire, the passes of Mozdak being difficult of access, and the country infested with predatory hordes. But there are other and more eligible means of communication,—viz., the Caspian on the east, and the Black Sea on the west. Over the former Russia now reigns paramount, no other vessels of war but her own being allowed to navigate there. In this vast reservoir the Volga, which is the great artery of Russia, pours its waters, collected during a navigable course of 2055 miles through some of the most fertile regions of the empire, and including in its tributaries those most distinguished for manufacturing industry, which is the main object. This noble stream communicating with the Baltic, there is an easy transport of goods insured from the remotest governments of the empire to the Caspian, and thence to the Transcaucasian territory. There is also on the other side a communication by the Black Sea, but it does not present so many advantages as that by the Caspian.

Islands of
Russia.

In the Baltic Sea are,—1. The Aland Islands, more than 100 in number, forming a group at the entrance of the Bothnian Gulf. They are almost all rocky; and the largest are Aland, Lemland, Eckerö, Fegle, and Brende. 2. Hochland, nearly in the middle of the Finnish Gulf, is a high granite cliff. 3. Kotlin, on which is situated the fortress of Cronstadt, one of the strongest in Europe. 4. Oesel. 5. Dago. 6. Worms. 7. Mon, on the western coast of Esthonia. 8. Runo, in the Gulf of Riga. Besides these, on the northern coast of Finland, lie a countless number of rocky islets called *scheeren*, often affording very picturesque scenery. In the Caspian Sea the islands are generally rocky. The most remarkable on the western coast are the Tiulën or Seals' Island, and the Zeeloy, on which the vine is cultivated. In the White Sea is the Solovetsky group, abounding with Muscovy glass or mica (*vitrum ruthenicum*.)

The islands in the Northern Ocean are,—1. Kolgooiëff, opposite Tchesk Bay, visited by the inhabitants of the go-

vernment of Arkhangel for its great quantity of geese and eider-down. 2. Novaia Zemliä, consisting of two large islands, separated by the Matotchkin Strait, and of several smaller ones. In June the Russian hunters resort hither for chasing the morse, sea-hares, and seals. 3. Waigats, at the north-eastern point of European Russia. 4. The Spitzbergen Archipelago. 5. The Lena Archipelago, situated at the mouth of the Lena, and the principal of which are New Siberia, Thaddeus, Kotèlni, and Liakhoff. 6. To the north of the Koleema lies the Bears' group. These islands are covered with snow during nearly the whole year. Their surface is generally rocky, and on some of them there are marks of volcanoes. They are chiefly remarkable for the teeth of the mammoth, rhinoceros, buffalo, and other animals found upon and beneath the surface of the ground. It was the search for ivory which originally induced the Russians to visit these regions, and their first exploring expedition was despatched in 1820. These islands are not inhabited, though traces of human beings have been discovered by the Russians engaged in the fisheries. Several kinds of shrubs are found, but no trees, although the shores are covered with drift wood. The southernmost point of these islands is in Lat. 69. 5., and they extend to Lat. 76. 20. Their longitude is between 154. and 183. 50. E. of Greenwich.

Asiatic
Russia.

These consist of the N.W. coast of America, extending on the south of Behring's Straits to 127. 30. W. Long. from London, with a narrow stripe of coast reaching as far south as 55. 30. of N. Lat. Further, of the islands lying to the south and east of Kamtschatka, enumerated as follows:—1. The Kurile group, twenty-two in number, and of which nineteen belong to Russia. They are all volcanic, and the few inhabitants are of Japanese origin. 2. The Commander's Group, comprising Behring's and Copper islands, on the latter of which Behring himself was buried. 3. The Aleutian Islands, divided into four groups,—the Bleezni or Near, the Rat, the Andreanoff, and the Fox groups. The largest of the Aleutian Islands is Oonalashka, 100 miles by 35. The volcano of Agazedan, on Ooni-mak, is 9000 feet above the water-level. 4. The Shoomagin; and 5. The Eudoxian, both to the south of the peninsula of Alaska. 6. Kadyak, to the east of Alaska. 7. Sitkha and the adjacent islands, lying on the extreme southern confine of the Russian coast. 8. The Prebecloff, to the north of the Aleutian. 9. St Matthew's Island; and 10. St Lawrence's, both to the north of Prebecloff's group. 11. Gvozdieff, or St Diomed's Island, in Behring's Straits. Every one of these islands is either a distinct mountain or the continuation of a chain. On the American continent the whole interior of the stripe extending from the southern border to Mount St Elias, is one continued mass of mountains, which sensibly declines as it approaches the Polar Sea and Eastern Ocean. The eastern parts of these possessions are covered with marshes and forests. The soil is mostly stony and the climate cold, though not so much so as in Kamtschatka. It is even warmer than the province of Yakootsk in Northern Asia. Thick fogs brood over these inhospitable shores; and the produce of the chase or fishing forms the sole source of riches to the natives. The population, on the 1st January 1858, in the American colonies of New Arkhangel, Kadyak, Oonalashka, Akhtinsk, the Kurile Islands, and Kenaisk Bay, amounted only to 5322 males and 4743 females, making a total of 10,065 souls; of which number 746 were Russians, 688 being males and 1838 Creoles, of whom 910 were males.

Russo-
American
possessions.

There were further in America 9 orthodox Greek churches and 35 chapels, besides 1 church at Ayan in Asia, altogether with 12,000 parishioners, of whom 9050 natives, called Koloshes, Kadyaks, Oonalashkins or Aleuts, Akhtins, Kenaitses, Tchoogatches, Alegmutes, and Koikhi-paktses, besides some Esquimaux. Five Creoles were or-

Rustchuk
||
Ruth, The
Book of.

dained clergymen. Not one crime had been committed during the last forty years. Many religious books had also been translated into the native tongues. The Spiritual Seminary of New Arkhangel had been transported to Yakootsk in Asia, and several schools existed at some of the colonial churches. A general colonial school was also about being established at the chief town, New Arkhangel, on the Island of Sitkha.

This, the progress of a country which, at the accession of Peter the Great in 1689, only 170 years ago, contained but 5,636,000 square miles, with 10 millions of inhabitants, and a revenue of L.403,125.

(Chief sources of reference applied to in the compilation of this article :—The Statistical Tables of 1858; the Statistical, Geographical, Military, and Naval *Sborniks*, or Gatherers of 1857 and 1859; Orsenieff's *Statistical Outlines of Russia*; Köppen's *Ethnographical Chart and Ninth Revision*; the Russian and Caucasian Calendars of 1859; the Government Chart of the Empire, besides sundry others; Kooznetsoff's *Geography*; *Views of Foreign and Internal Trade*; Tengoborski's *Productive Strength*; Lamanski's various works on Russian Finance; Nebolsin's

Internal Trade, and Thörner's continuation of this work; Rutherford Aksakoff's *Fairs of Russia*; Troinitski's pamphlet on the Serfs, and Statistical Chart; Oostrialoff's *History; Dissertations on the Eastern Catholic Church*, by Palmer; *Unterscheidungslehren der Christlichen Bekenntnisse*, by Graul; Hanusch, *Slavonian Mythology*; Ritter's *Asien*; *L'Asie Centrale*, par A. de Humboldt. The rest is completed from the writer's own personal knowledge. The best foreign writers on Russia are Schnitzler and Haxthausen, although their works contain numerous errors, and are becoming antiquated; the best national writers are Tengoborski and Tcheffkin. The works edited by Demidoff are also noteworthy; but Russia is still much in want of an able expositor in several points of view, as the country is much misrepresented. We are much beholden to Professor Oosoff, Colonel Uslar, and Councillor Tetera; besides being particularly indebted for unwearied attentions to Baron von Behr, Academicians Vesseloffski and Kupffer, State-Councillors Lamanski, Khvostoff, Gaieffski, and last, though not least, to the Rev. E. E. Law, D.D., and R. Winkler, M.D., both of St Petersburg.) (J. H. B.—P.)

RUSTCHUK, a town of European Turkey, in Bulgaria, on the right bank of the Danube, here about 2 miles broad, opposite Giurgevo, and 55 miles below Nicopolis. It stands on a series of low hills, among extensive orchards, from the midst of whose foliage it rises conspicuous with its white chimneys and minarets. Extensive fortifications surround the town, and a citadel commands the passage of the river. The buildings are generally mean-looking, but there are several mosques, Greek and Armenian churches, synagogues, bazaars, and baths. Rustchuk is the seat of a Greek archbishop and of a Turkish pasha. There are some manufactures of woollen and cotton cloth, silk, leather, linen, and tobacco: while an active trade is carried on with Constantinople and Wallachia. For river navigation there is a harbour under the walls of the citadel. A battle was fought here between the Turks and the Russians in 1811, after which the town was taken by the latter. Rustchuk is inhabited by Turks, Wallachians, Greeks, and Jews. Pop. 30,000.

RUTH, THE BOOK OF, is inserted in the Scripture canon, according to the English arrangement, between the book of Judges and the books of Samuel, as a sequel to the former and an introduction to the latter. Among the ancient Jews it was added to the book of Judges, because they supposed that the transactions which it relates happened in the time of the judges of Israel (Ruth i. 1). Several of the ancient fathers, moreover, make but one book of Judges and Ruth. But the modern Jews commonly place in their Bibles, after the Pentateuch, the five Megilloth—1. The Song of Solomon; 2. Ruth; 3. The Lamentations of Jeremiah; 4. Ecclesiastes; 5. Esther. Sometimes Ruth is placed the first of these, sometimes the second, and sometimes the fifth. The true date and authorship of the book are alike unknown, though the current of authority is in favour of Samuel as the writer. That it was written at a time considerably remote from the events it records, would appear from the passage in ch. iv. 7, which explains a custom referred to as having been "the manner in former time in Israel, concerning redeeming and concerning changing" (comp. Deut. xxv. 9). That it was written also at least as late as the establishment of David's house upon the throne, appears from the concluding verse—"And Obed begat Jesse, and Jesse begat David." The expression, moreover (ch. i. 1), "when the judges ruled," marking the period of the occurrence of the events, indicates, no doubt, that in the writer's days kings had already begun to reign. The canonical authority of

Ruth has never been questioned, a sufficient confirmation of it being found in the fact that Ruth the Moabitess comes into the genealogy of the Saviour, as distinctly given by the evangelist (Matt. i. 6). The principal difficulty in regard to the book arises, however, from this very genealogy, in which it is stated that Boaz, who was the husband of Ruth, and the great-grandfather of David, was the son of Salmon by Rachab. Now, if by Rachab we suppose to be meant, as is usually understood, Rahab the harlot, who protected the spies, it is not easy to conceive that only three persons—Boaz, Obed, and Jesse, should have intervened between her and David, a period of nearly 400 years. But the solution of Usher is not improbable, that the ancestors of David, as persons of pre-eminent piety, were favoured with extraordinary longevity. Or it may be that the sacred writers have mentioned in the genealogy only such names as were distinguished and known among the Jews.

The leading scope of the book has been variously understood by different commentators. Umbreit ("Ueber Geist und Zweck des Buches Ruths," in *Theol. Stud. und Krit.* for 1834, p. 308) thinks it was written with the specific moral design of showing how even a stranger, and that of the hated Moabitish stock, might be sufficiently noble to become the mother of the great king David, because she placed her reliance on the God of Israel. Bertholdt regards the history as a pure fiction, designed to recommend the duty of a man to marry his kinswoman; while Eichhorn conceives that it was composed mainly in honour of the House of David, though it does not conceal the poverty of the family. The more probable design we think to be to pre-intimate, by the recorded adoption of a Gentile woman into the family from which Christ was to derive his origin, the final reception of the Gentile nations into the true church, as fellow-heirs of the salvation of the gospel.

RUTHERFORD, SAMUEL, a divine celebrated for his piety and learning, was born about 1600 at the village of Nisbet in Roxburghshire, and was educated for the church at the university of Edinburgh. Being appointed in 1627 to the parish of Anwoth in Kirkcudbrightshire, he addressed himself to his work with a holy zeal. He rose in the morning at three o'clock to meditate and pray. The care of his poor, ignorant flock occupied his every thought. Many of them by name were made the subject of his frequent wrestlings with God. Even his very dreams were disturbed with anxiety on their account. Nor after he had been deposed and banished from his office in 1636, for

Ruther-
glen
||
Ruthin.

preaching against the Articles of Perth, did he forget his charge. No sooner was Episcopacy overthrown in 1638 than he hastened home from Aberdeen to Anwoth. After his settlement in 1639 as professor of divinity in St Mary's College, St Andrews, Rutherford began to take a prominent part in the politics of the church. He was sent up to London in 1643 as one of the commissioners from Scotland to the Westminster Assembly. Remaining there at his post for four years, he did great service to the cause of his party. He exerted himself to get his peculiar views embodied in the *Shorter Catechism* which was then drawn up. So great also were his efforts in favour of Presbyterianism that Milton attacked him by name in the poem entitled *On the New Forcers of Conscience under the Long Parliament*. At the same time, his pen was busily employed in the same cause. He published *The Due Right of Presbytery*, 1644; *Lex Rex*, 1644; *The Trial and Triumph of Faith*, 1645; and *The Divine Right of Church Government*, 1646. The last days of Samuel Rutherford were assailed by the persecution which followed the Restoration in 1660. His *Lex Rex* was burnt in front of his own windows. All his offices were taken from him. He himself would also have been arraigned before the Parliament had he not been summoned away before a superior judicatory on the 20th March 1661. (See *The Letters of the Rev. Samuel Rutherford, accompanied with a Sketch of his Life*, by the Rev. A. A. Bonar, Edinburgh, 1848.)

RUTHERGLEN, or RUGLEN, a parliamentary, municipal, and royal burgh of Scotland, county of Lanark, on the left bank of the Clyde, 2 miles S.E. of Glasgow. It has one main street of considerable breadth, extending from E. to W., and many smaller streets and lanes diverging from it. There are no public buildings of any importance except the town-hall, parish church, chapel of ease, Free and United Presbyterian churches. The parish church is ancient, and it is said to have been here that the treaty was made in 1297 between Edward I. of England and Sir John Menteath, by which the latter agreed to betray Wallace to the English. The castle that formerly stood at Rutherglen was demolished by the Regent Murray. The town contains a court-house, prison, and several schools. The inhabitants are very generally employed in hand-loom weaving. There are chemical works, print and dye works here; and in the vicinity several coal mines. Formerly the town was of considerable importance, and had a large trade on the Clyde; but this has been absorbed by Glasgow, with the suburbs of which Rutherglen is connected by an old narrow bridge. Several annual fairs are held. The burgh was first chartered by David I. in 1126, and is governed by a provost, two bailies, and eighteen councillors. It unites with Kilmarnock, Dumbarton, Port-Glasgow, and Renfrew in returning a member to Parliament; and the constituency is 194. The value of real property, 1858-9, was L.23,304; and the corporation revenue, 1857-8, L.1633. Pop. (1851), 7104.

RUTHIN, a market-town, parliamentary and municipal borough of Wales, in the county and 8 miles S.E. of Denbigh, 195 N.W. by W. of London. It stands on the sides and top of a hill on the left bank of the Clwyd. The ancient castle, which was founded by Edward I., was taken after a siege of two months by the parliamentary forces in 1646, and afterwards dismantled. Recently a castellated mansion-house has been erected on the site. In the market-place of the town stands the town-hall, a substantial building of the seventeenth century. Ruthin has also a handsome court-house, a grammar and other schools, and a jail. The church is ancient, and has a much-admired oak roof. The other places of worship belong to Baptists, Independents, and Methodists. The inhabitants are chiefly employed in farming. Markets are held twice a week, and there are several annual fairs. The borough is governed

by a mayor, three other aldermen, and twelve councillors; and it unites with Denbigh, Holt, and Wrexham in returning a member to Parliament. Pop. (1851), 3373.

RUTILIUS LUPUS, a Roman rhetorician of the time of Cicero, has left behind him a treatise *De Figuris Sententiarum et Elocutionis*. This treatise was merely an abridgment from the work of a contemporary, Gorgias of Athens. The one book of which it originally consisted was divided into two by some of its subsequent editors. Its chief value in the present day is derived from its numerous quotations from the works of Greek authors now lost. The *editio princeps* of Rutilius was printed by Zoppinus at Venice, 8vo, 1519. The best edition is that of Ruhnken, 8vo, Leyden, 1768.

RUTILIUS NUMATIUS, *Claudius*, a Latin poet of the fifth century, was a native of Gaul, and, sojourning in Rome for some time, held the high office of *præfectus urbi*. His style was formed after the best models in the language, and his spirit was truly poetical. The subject of his verse was his return by sea from Italy to his native country. He described the scenery which he saw as he coasted along the shores, and the people whom he met in the towns at which he touched. Among other subjects, he attacked the monks, and lamented the ravages committed by the barbarians of the north. This poem of Rutilius has come down to us in an imperfect state, under the title of *Itinerarium* or *De Reditu*. The *editio princeps* was printed at Bologna, 4to, 1520. The best edition is that of Zumpt, Berlin, 1840.

RUTLANDSHIRE, an inland county of England, the smallest in size of the whole, bounded on the N.E. by Lincolnshire, S.E. by Northamptonshire, W. and N.W. by Leicestershire: length, from N.E. to S.W., about 20 miles; greatest breadth, 16; area, 150 square miles, or 95,805 acres. It is divided into five hundreds, and contains two market-towns, Uppingham and Oakham, and fifty-seven parishes, besides two extra parochial districts.

It gives only one title at present, that of duke, to the family of Manners; two former peerages, that of Ferrars of Okeham, and Noel of Exton, being extinct. Only two members are returned to the House of Commons from the county, and none from either of the towns. In judicial affairs it is on the midland circuit of the judges; and in ecclesiastical matters it has formed, since the year 1541, a portion of the bishopric of Peterborough.

The appearance of this small county is pleasing to the traveller. It is much diversified by ranges of moderate hills running from east to west, in some parts well wooded. Between these ranges of hills, the valleys, of about half a mile in breadth, are luxuriant and verdant. The principal vale, called Catmoss, is in the centre of the county, having to the north a tract of table-land overlooking the well-wooded plains of Leicester, Lincoln, and Nottinghamshire. The rivers of Rutlandshire all discharge their waters into the estuary called the Wash. The largest of them is the Welland, which flows in a N.E. direction along the border of the county, separating it from that of Northampton. The Chater, the Wash, the Eye, and the Wreak are all affluents of the Welland, flowing from W. to E., through various valleys in Rutlandshire. The geological formations of the county belong to the lower part of the oolite series of deposits. Limestone is the prevailing rock in the table-land that occupies the northern and also in the south-eastern part of the county. The south-western portion is mostly occupied by the reddish sands that separate the oolitic formation from the lias that underlies it. There are good stone quarries at Ketton, on the south-east border of the county.

The soil on the eastern and south-eastern parts is chiefly shallow, resting upon a basis of limestone, composed of clays and loams. The other parts consist principally of a

Rutilius
||
Rutland-
shire.

Rutna-
gherry.

tenacious but fertile loam; but the vale of Catmoss enjoys a most fertile soil of good clay, or red loam, or a grateful mixture of both these earths. A peculiarity of the soil is a redness, which generally prevails, and which tinges all the waters of the country. A great part of the area, especially in the west, is laid out in pasture; the eastern portion is mostly occupied by farms; and hardly any part is waste.

The woods of this county were far more extensive in former ages than they are at present, but they are still estimated to cover nearly 3000 acres. The climate is generally accounted peculiarly soft and healthy; and the elevation is of that medium kind which equally exempts it from the pernicious effects of moist exhalations and cold mountain fogs.

The agriculture, though it has partaken of some modern improvements, is not upon the whole conducted in the best manner. Large crops of wheat and barley are reared; but it is chiefly for its pastures that Rutlandshire is remarkable. The cattle are for the most part shorthorns; but other breeds are also to be met with. The cows are remarkable for the richness of their milk, though they yield but a small quantity. The rich cheese commonly known as Stilton is chiefly made in the dairies of this county. Most of the sheep are of the Leicester breed. Hogs of the Berkshire and the Suffolk breeds are raised; and many strong dray horses are sent from Rutlandshire to London. The farms have for the most part an extent of 15 acres and upwards, and the farm-houses are good old-fashioned buildings.

Rutlandshire is neither a manufacturing nor a mineral district, but depends exclusively on its agriculture. It is traversed by numerous roads, by a canal from Melton Mowbray to Oakham, and by lines of railway connecting Peterborough with Leicester and Rugby. The principal seats of noblemen and gentlemen in the county are Exton Park, belonging to the Earl of Gainsborough; Normanton Hall, to Baron Aveland; Cottesmere, to the Earl of Lonsdale; Glaiston, to the Earl of Harborough; and Burley, to G. Finch, Esq. The last-mentioned place belonged at one time to the Duke of Buckingham, who entertained here on several occasions James I. and Charles I. It was afterwards purchased by the Earl of Nottingham, who erected the present splendid mansion. There are few remains of antiquity in the county; and these are mostly to be found in the churches, some of which are of Norman architecture, and beautifully ornamented. According to the census of 1851, the county contained in all 91 places of worship, with 17,399 sittings. Of the former, 53 belonged to the Church of England, 18 to Wesleyan Methodists, 12 to Baptists of various denominations, 6 to Independents, and 1 each to Quakers and Mormonites. According to the same returns, Rutlandshire contained 39 public day schools and 74 private ones,—in all, 113; attended by 3405 children. Of the public schools, 2 were workhouse schools, supported by taxation, 15 were supported by endowments, and 22 by the Church of England. There were also 58 Sunday schools, with 3038 scholars. The only literary institution is the Rutland Farmers' and Graziers' Club, which has 40 members, and a library of 80 volumes. By the returns of 1801, the inhabitants were 16,300; in 1811 the numbers were 16,380; in 1821 they were 18,487; in 1831 the numbers were 19,385; in 1841, 21,302; and in 1851 22,983.

RUTNAGHERRY, a collectorate of British India, in the presidency of Bombay, stretches along the shore of the Indian ocean, bounded on the N. by the collectorate of Tannah, E. by those of Sattara and Kolapore, S. by Sawunt Warree and the Portuguese territory of Goa, and W. by the sea. It lies between N. Lat. 15. 44. and 18. 6., E. Long. 73. 6. and 73. 58: length, from N. to S., 167 miles; greatest breadth, 40; area, 3964 square miles.

The surface is in general very rugged, being occupied in many parts with mountains and jungle, and intersected with torrents, which rush down from the western ghauts to the sea. Only a small part of the soil is arable, but the facilities for water communication with the coast, where a ready market is found for agricultural produce, induce the peasant to make the most of his available ground. But this region is almost entirely cut off from the Deccan by the mountains, through which there are only a few passes, while communication is greatly impeded by the want of good roads and bridges. Rice and grain are the principal crops raised in the district; no great success has attended the efforts made to introduce more valuable kinds of produce. Pop. 665,238.

RUTULI (Ρούτουλοι), a people of ancient Italy, who settled at an early period in a portion of Latium adjoining the sea-coast, their capital city being Ardea, have acquired considerable celebrity from the prominent part which their king, Turnus, played in the settlement of Æneas, as poetically told by Virgil. An old tradition representing Ardea as founded by a colony from Argos has led Niebuhr to conjecture the Pelasgic origin of the Rutuli. (Nieb. vols. i. and ii.) Schwegler again considers them as Etruscans (*Röm. Gesch.*, vol. i.); but the whole subject is so bound up with poetical invention, that it is almost impossible to extract the smallest grain of truth from it.

RUYSCH, FREDERIC, one of the most eminent anatomists of which Holland can boast, was born at the Hague in 1638. After making great progress at home, he repaired to Leyden, and there prosecuted the study of anatomy and botany. He next studied at Franeker, where he obtained the degree of Doctor of Physic. He then returned to the Hague, and, marrying in 1661, dedicated his whole time to the study of his profession. In 1665 he published a treatise entitled *Dilucidatio Valvularum de variis Lymphaticis et Lacteis*, which raised his reputation so high that he was chosen professor of anatomy at Amsterdam. This honour he accepted with the more pleasure, because his situation at Amsterdam would have given him easy access to every requisite help for cultivating anatomy and natural history. After he settled in Amsterdam he was perpetually engaged in dissecting, and in examining with the most inquisitive eye the various parts of the human body. He improved the science of anatomy by new discoveries; and, in particular, he found out a way to preserve dead bodies many years from putrefaction. His anatomical collection was curious and valuable. He had a series of fœtuses of all sizes, from the length of the little finger to that of a newborn infant. He had also bodies of full-grown persons of all ages, and a vast number of animals of almost every species on the globe, besides a great many other natural curiosities. Peter the Great of Russia, in his tour through Holland in the year 1698, visited Ruysch, and was so charmed with his conversation that he passed whole days with him; and when the hour of departure came, he left him with regret. He set so high a value on Ruysch's cabinet of curiosities that when he returned to Holland in 1717 he purchased it for 30,000 florins, and sent it to St Petersburg. In 1685 he was made professor of medicine, an office which he discharged with great ability. In 1728 he got his thigh-bone broken by a fall in his chamber. Ruysch is said to have been of so healthy a constitution that, though he lived to the age of ninety-three, yet during that long period he did not labour above a month under the infirmities of disease. From the time he broke his thigh he was disabled from walking without a support; yet he retained his vigour both of body and mind without any sensible alteration, until in 1731 his strength at once deserted him. He died on the 22d of February of the same year. His anatomical works are printed in 4 vols. 4to. His second collection in natural history and

Rutuli
||
Ruysch.

Ruysdael
||
Ruyter.

anatomy was sold at his death to the King of Poland for 20,000 florins.

The style of his writings is simple and concise, but sometimes inaccurate. Instruction, and not ostentation, seems to be his only aim. In anatomy he undoubtedly made many discoveries; but from not being sufficiently conversant with the writings of other anatomists, he published as discoveries what had been known before. The Academy of Sciences at Paris in 1727 elected him an honorary member, in place of Sir Isaac Newton, who had lately deceased. He was also a member of the Royal Society of London.

RUYSDAEL, or RUISDAEL, JACOB, the prince of Dutch landscape-painters, was born at Haerlem in 1630, and is said to have studied under Berchem. Settling in his native country, he commenced to paint landscapes with unsurpassed success. His eye sought for subjects under every aspect of nature. He selected a wide sweep of meadow-land, a wooded hamlet, or a frozen canal with unfailing artistic skill. His lively fancy imparted to the scene its appropriate poetic feeling, and his hand copied the whole with exquisite fidelity. But it was especially in the wild and the magnificent that Ruysdael was at home. His ardent imagination loved to exercise itself in imitating the lawless strength of nature. Tempestuous seas and rude forest landscapes came out upon the canvas with all the striking effect of reality. Ruysdael died at Haerlem in 1681. Specimens of the works of this great painter are found in most of the principal collections in Europe. There is a landscape in Worcester College, Oxford, a church interior in Lord Bute's collection, and two landscapes in the National Gallery of Scotland. His masterpiece, a "Stag-Hunt," is in the Dresden gallery. The figures in his pictures are painted by Philip Wouwerman, Adrian Vanderveelde, or Berchem. Jacob Ruysdael's elder brother Solomon was also a landscape-painter.

RUYTER, MICHEL ADRIAN, a distinguished naval officer, was born at Flushing, a town of Zealand, in the year 1607. He entered on a seafaring life when he was only eleven years old, and was first a cabin-boy. Whilst he advanced successively to the rank of mate, master, and captain, he acquitted himself with ability and honour in all these employments. He repulsed the Irish, who attempted to take Dublin out of the hands of the English; he made eight voyages to the West Indies, and ten to Brazil; he was promoted to the rank of rear-admiral, and sent to assist the Portuguese against the Spaniards. When the enemy came in sight he advanced boldly to meet them, and gave such unquestionable proofs of valour as drew from the Portuguese monarch the warmest applause. His gallantry was still more conspicuous before Sallee, a town of Barbary. With a single vessel he sailed through the roads of that place, in defiance of five Algerine corsairs who came to attack him.

In 1653 a squadron of seventy vessels was despatched against the English, under the command of Admiral Van Tromp. Ruyter, who accompanied the admiral in this expedition, seconded him with great skill and bravery in the three battles which the English so gloriously won. He was afterwards stationed in the Mediterranean, where he captured several Turkish vessels. In 1659 he received a commission to join the King of Denmark in his war with the Swedes. As a reward of his services, the King of Denmark ennobled him and gave him a pension. In 1661 he grounded a vessel belonging to Tunis, released forty Christian slaves, made a treaty with the Tunisians, and reduced the Algerine corsairs to submission. His country, as a testimony of her gratitude for such illustrious services, raised him to the rank of vice-admiral and commander-in-chief. To the latter dignity, the highest that could be conferred upon him, he was well entitled by the signal victory which he obtained over the combined fleets of France and

Ryde
||
Rye.

Spain. This battle was fought in 1672, about the time of the conquest of Holland. The battle was prosecuted between the English and Dutch with the obstinate bravery of nations which were accustomed to dispute the empire of the ocean. Ruyter having made himself master of the sea, conducted a fleet of Indiamen safely into the Texel; thus defending and enriching his country, whilst it had become the prey of hostile invaders. The next year he had three engagements with the fleets of France and England, in which, if possible, his bravery was still more distinguished than ever. But he did not long enjoy the triumphs which he had so honourably won. In an engagement with the French fleet off the coast of Sicily he was defeated, and received a mortal wound, which in a few days put an end to his life. His corpse was carried to Amsterdam, and a magnificent monument to his memory was there erected by the command of the States-General. The Spanish Council had bestowed on him the title of Duke, and transmitted a patent investing him with that dignity; but he died before it arrived. When Louis XIV. was congratulated upon De Ruyter's death, he replied, "Every one must be sorry at the death of so great a man." (See the *Life of M. A. Ruyter*, by G. Brandt, Amsterdam, 1690.)

RYDE, a market-town of England, Hampshire, on a hill on the N.E. coast of the Isle of Wight, 7 miles N.E. by E. of Newport, and 75 S.W. by S. of London. It is a modern place, and has broad, straight, and well-paved streets. The houses, which are considerably varied in their appearance, and generally surrounded with gardens, rise tier above tier from the sea-shore, and have, when seen from Portsmouth, a striking and picturesque aspect. One of the finest public buildings is that which includes the market-house and town-hall, a Doric structure, 198 feet by 56. There are numerous places of worship in the town, of which 3 belong to the Church of England, and are under the parish church of Newchurch, 7 miles distant. The others belong to Independents, Baptists, Methodists, and Roman Catholics. Ryde has also several schools, a literary and scientific institution, and a dispensary. One of the most elegant buildings is that of the Royal Victoria Yacht Club, recently erected. There are also a theatre, baths, public libraries, and reading-rooms, assembly-rooms, and a fine arcade. The pier, which has been recently built at considerable expense, is 1740 feet in length, and forms a favourite promenade. Ryde is a much-frequented resort for visitors during the summer months, and the accommodation it affords to strangers has been recently much increased. Steamers ply regularly between this and Portsmouth. The neighbourhood is very beautiful, and contains many fine mansions. There are at Ryde building-yards for boats and yachts; and the town exports, among other articles, corn, flour, calves, sheep, and lambs. Vessels bound for the East and West Indies often touch here for provisions. Pop. (1851) 7147.

RYE. See AGRICULTURE.

RYE, a market-town, municipal and parliamentary borough of England, one of the cinque ports, in the county of Sussex, on the right bank of the Rother, at its mouth, 38 miles E.N.E. of Lewes, and 63 S.E. of London. It is built on the northern and eastern slopes of a hill, and has some regular streets lined with old, substantial, and not very uniform houses. The houses are for the most part built of brick, as also is the town-hall, a neat edifice, raised on arches, beneath which is a market-place. The parish church is a large building in the form of a cross, with a central tower. It is partly in the Norman and partly in the early English style. There are also places of worship belonging to Methodists, Independents, and Baptists. The educational establishments comprise two endowed schools, a free grammar school, and national schools. The town has also alms-houses and other charitable institutions. Rye

Rymer. has always depended very much for its prosperity on the harbour. This was at one time very good; but the gradual deposition of sand in the mouth of the Rother, where the harbour is, went on to such an extent that in the sixteenth century it was nearly choked up. In 1750 an attempt was made to form by a canal a new mouth to the river; but this proved unsuccessful, and was abandoned in 1778. The old harbour was then improved by a wooden pier at one side and embankments at the other, which narrowed and deepened the channel; but even with this improvement it can only admit of vessels of 200 tons burden. The entrance, too, is difficult, and the harbour is dry at low water. The number of sailing-vessels registered at the port, 31st December 1857, was 120, tonnage 7218; of steamers 1, tonnage 21. In the year ending on that day the number of sailing-vessels that entered was 484, tonnage 40,849; those that cleared 133, tonnage 9024. The principal articles of export are wool, oak timber, bark, and hops. Coal, corn, and Dutch produce are imported. The fisheries are somewhat productive. In the town are ship-building yards, and in the vicinity lime-kilns. The borough is governed by a mayor, three other aldermen, and twelve councillors. It returns a member to the House of Commons. Rye is a very ancient place, and is supposed to be the *Novus Portus* of the Romans. In the reign of Stephen a castle, which still remains, and is now used as a jail, was erected here; and by order of Edward III. the town was walled on all sides, except where steep cliffs defended it towards the sea. One of the gates of this period still remains. Pop. of the borough (1851) 8541.

RYMER, THOMAS, the author of that well-known and important work the *Fœdera*, was born in Yorkshire in 1638 or 1639, and was educated at the grammar-school of Northallerton. He was admitted a scholar at Sydney Sussex College, Cambridge; then became a member of Gray's Inn in 1666; and at length was appointed historiographer to King William, in place of Shadwell, in 1692. He wrote a *View of the Tragedies of the Last Age*, and a tragedy named *Edgar, or the English Monarch*. For a critic he was certainly not well qualified, for he wanted candour; nor is his judgment much to be relied on who could condemn Shakspeare with such rigid severity in his *Short View of Tragedy*, 1693. His tragedy will show that his talents for poetry were by no means equal to those whose poems he has publicly censured. In 1694 appeared his translation of Rapin's *Reflections on Aristotle's Treatise of Poesie*. But though he has no title to the appellation of poet or critic, as an antiquarian and historian his memory will long be preserved. His *Fœdera*, which is a collection of all public documents of the kings of England with foreign princes, is esteemed one of our most authentic and valuable records, and is oftener referred to by the best English historians than any other book in the language. It was published at London in the beginning of the eighteenth century, in 17 vols. folio. Three volumes more were added by Sanderson after Rymer's death. The whole were reprinted at the Hague in 10 vols., 1739. They

were abridged by Rapin in French, and inserted in Le Clerc's *Bibliothèque*, a translation of which was made by Stephen Whatley, and printed in 4 vols. 8vo, 1731. Rymer died on the 14th of December 1713, and was buried in the parish church of St Clement Danes. Some specimens of his poetry are preserved in the first volume of Nichol's *Select Collection of Miscellaneous Poems*, 1780.

RYOTS, the name given to the cultivators of the soil in Hindustan. (See HINDUSTAN.)

RYSBRACK, RYSBRAECK, or RYSBRECHTS, PETER, a Flemish painter, was born at Antwerp in 1657, and received his rudimentary instruction in the studio of Francis Milé, whom he afterwards accompanied to Paris. He made a special study of the works of Gaspar Poussin, and received flattering encouragement to remain in Paris. He returned, however, to his native country, and exercised his talents in Antwerp with great reputation. Rysbrack possessed great harmony in the distribution of his colours, had a broad and free touch, and great facility of execution, but there was a monotony and want of variety about his pictures, which placed him on a much lower level than the master whom he imitated. He died about 1716.

RYSBRACK, *Michael*, a distinguished Flemish sculptor, was born at Antwerp according to the testimony of Charles Rogers, who knew him well, on the 24th of June 1693. His father, Peter Rysbrack, the painter, already noticed, placed him early with Michael Vander Vorst, with whom he remained till 1712. He came to London in 1720, and was for a time obscurely engaged in executing monumental works for Gibbs, who industriously farmed out these ornamental works to the lowest bidder. Having rid himself of Gibbs, he soon brought himself into notice, so that there was no piece of monumental art executed in England of any importance that did not pass through his hands. He gave a great impulse to sculpture in England, and so great was his reputation, that men used to recount in remote districts of the country, as the greatest event of their lives, their having had the honour of visiting the workshop of Rysbrack of Vere Street, London. Form and character were his exclusive study; and he had very slender regard for his illustrious countrymen, Rubens and Rembrandt. For many years he may be said to have had the sculpture of Britain at his feet, but on the appearance of Scheemacker and Roubiliac, he had to recognize two successful rivals. During his career he executed busts of Pope, Ben Jonson, Butler, Milton, Cromwell, Sir Hans Sloane, Locke, and many others, besides erecting numerous monuments in Westminster Abbey and elsewhere. He died January 8, 1770. (See SCULPTURE.)

RZESZOW, a town of the Austrian empire, capital of a circle in Galicia, in a deep valley, 94 miles W. by N. of Lemberg. It has a large castle, a school, linen factories, and some trade in linen. About half of the inhabitants are Jews; and many are employed in making jewellery of a sort of false gold, with or without precious stones. This is sold not only at home, but in other countries, especially in Wallachia. Pop. 6700.

Ryots
||
Rzeszow.

S.

S
||
Saadi.

S, the nineteenth letter and chief sibilant of the English alphabet. The sound of it is formed by forcing the breath through a narrow passage between the palate and the tongue elevated near it, together with a motion of the lower jaw and teeth, towards the upper jaw. Its sound, however, varies, being strong in some words, as *this*, *thus*, and soft in words which have a final *e*, as *muse*, *wise* (pronounced *z*). It is generally doubled at the end of words, by which they become hard and harsh, as in *kiss*, *loss*. In some words it is silent, as *isle*, *island*, *viscount*. It is subject to numerous interchanges, which are observable in most languages. The following are the best known:—S interchanges with *d*, *th*, *t*, *z*, *sh*, *c*, *g*, *h*, *ks*, with *g*, *n*, and *r*. The letter S is frequently dropped, of which we have numerous examples in the history of the French language.

In abbreviation, S. stands for *societas* or *socius*; as R.S.S. for *regiæ societatis socius*, fellow of the royal society. In medicinal prescriptions, S.A. signifies *secundum artem*, according to the rules of art. And in the notes of the ancients, S. stands for *Sextus*; S.P. for *Spurius*; S.C. for *senatus consultum*; S.P.Q.R. for *senatus populusque Romanus*; S.S.S. for *stratum superstratum*, one layer above another alternately; S.V.B.E.E.Q.V. for *si vales bene est, ego quoque valeo*, a form used in Cicero's time in the beginning of letters. (See ABBREVIATIONS.) Used as a numeral, S. anciently denoted seven; in the Italian music, S. signifies *solo*; and in books of navigation, S. stands for south, S.E. for south-east, S.W. for south-west, S.S.E. for south-south-east, S.S.W. for south-south-west.

SAAD-ED-DEEN, MOHAMMED EFFENDI, a celebrated Turkish historian, was born in the early part of the sixteenth century, and was educated among the pages of the imperial palace. The influence of his father and his own acquirements raised him to a high position in the world. Several emperors in succession patronized him. Selim II. made him preceptor to his son the heir-apparent. Mourad III. appointed him military judge, and instituted for him the new office of imperial historiographer. Still more marked were the favours of Mohammed III. He kept him in his presence as his confidential councillor, raised him to the dignity of mufti, and continued to cherish him till death carried him off in 1599. The great work of Saad-Ed-Deen treats of the history of the Ottoman empire from its foundation by Ottoman to the death of Selim I. in 1520. Speaking of it, Sir William Jones says that, "for the beauty of its composition and the richness of its matter, it may be compared with the finest historical pieces in the languages of Europe." It is still in manuscript.

SAADI, surnamed MOSLIH EDDIN, one of the most celebrated of the Persian poets, was born at Shiraz about 1175, and after receiving his education at the college of Bagdad, became a dervish. In the early part of his life he was known as a great traveller. His frame was strong and vigorous, and his temperament healthy and sunny. The free air and the light of many-coloured life were pleasant to his soul. He was ever on foot venturing into all sorts of countries, associating with all sorts of people, and meeting with all sorts of adventures. He cracked his jokes in India, fought against the infidels in Asia Minor, and was for some time a prisoner in the hands of the Crusaders at Tripoli. At the end of thirty years, however, Saadi settled down. Building a hermitage near the walls of Shiraz, he secluded himself from the world. His time was chiefly engrossed in digesting his large experience of men and manners, and in embodying it in his poetry and prose works. Many persons of rank broke in upon his retire-

ment and heaped his board with gifts, but they could not affect his spirit of austerity. He appropriated part of their bounty for his own simple wants, and bestowed the rest upon the poor. Thus did the peaceful years pass by until his death, which occurred in 1291, at the advanced age of 116. Saadi's collected works were printed in the original in 2 vols., Calcutta, 1791. They consist of the *Gulistan*, *Bostan*, odes, elegies, fragments, quatrains, and essays of various kinds. By far the best known is the *Gulistan* and *Bostan*. The former is a composition of eight chapters of prose, with occasional intermixtures of verse, either from the author's own pen, or from that of some of his predecessors. The chapters treat of the morals of kings, the morals of dervishes, the excellency of contentment, the advantages of taciturnity, on love and youth, on imbecility and old age, on the effects of education, and rules for the conduct of life. They consist for the most part of unconnected moral stories, unlike in their mutual relation to other oriental collections, such as the Arabian Nights, or the Fables of Pilpay or Bidpai, whose consecution is ordinarily that of subordination to the more general story. All the connection manifest in these Persian tales is that of their allusion to a common subject. There have been numerous versions of this book. It has been translated into French by Du Ryer, 1634; by another Du Ryer in 1789; and by Semelet, Paris, 1834; a spirited German translation by Olearius, 1654; another more recent one by K. H. Graf, 1846; into Dutch, 1654; into English by Gladwin, 1808; by Ross for the Asiatic Society, and by Eastwick in prose and verse, who edited the original two years before, Hertford, 1852. The *Gulistan* is considered the best text-book for students learning Persian. There is a good life of Saadi given by Harrington, in his edition of his works (1791), translated from the Persian of Dowlet Shah.

SAALE, a river of Germany, rises on the northern slope of the Fichtelgebirge, in the N.E. of Bavaria, and flows in an irregular course, generally northwards, through the Saxon duchies. It waters the states of Reuss, Schwartzburg, Rudolstadt, Saxe-Meiningen, Saxe-Altenburg, and Saxe-Weimar, and enters the Prussian province of Saxony. Finally, after traversing the duchy of Anhalt-Bernburg, it falls into the Elbe 6 miles below Calbe. Its whole length is 200 miles; and it is navigable for large vessels as far up as Halle. The principal other towns on its banks are Hof, Saalfeld, Jena, Merseburg, and Bernburg. It receives from the right the Elster and other smaller streams, and from the left the Ilm, Unstrut, and others.

SAALFELD, a town of Saxe-Meiningen, on the left bank of the Saale, in the midst of the Thuringian forest, 41 miles E. of Meiningen. It is an old town, surrounded by walls, and containing many venerable buildings. Among these are the Gothic town-hall, and the church of St John, built in 1212, remarkable for its fine painted glass, and for a colossal wooden statue of the saint. There is a ducal palace in the town now used as a mint, and another in the suburbs with extensive gardens. Near the walls stand the remains of an old fort, said to have been built by Charlemagne to resist the incursions of the Slavonic tribes. Pop. 4550.

SAARBRÜCK, or SARREBRÜCK, a town of Prussia, near the frontiers of France, in the province of the Rhine, government and 40 miles S.S.E. of Treves. It stands on the left bank of the Saar, and is connected by a stone bridge with the suburb of St John on the opposite side. There was formerly a palace here, belonging to the princes of Nassau-Saarbrücken, but it was destroyed by the

Saale
||
Saarbrück.

Saarlouis
||
Sabatier.

French in 1793. Saarbrück contains a gymnasium, manufactures of tobacco, woollen stuffs, hardware, &c., and has a considerable trade. In the vicinity there are rich coal mines. Among these is one very remarkable, as it has been burning in the interior for 180 years, and on its surface, even in the severest winter, no snow lies. Pop. 9514.

SAARLOUIS, or SARRELOUIS, the frontier fortress of Prussia towards France, on the left bank of the Saar, in the province of the Rhine, government and 43 miles S. of Trèves. It occupies a peninsula formed by the river, and is strongly fortified; the works were constructed by Vauban in 1681, in the course of one year. There are a Protestant and a Roman Catholic church, a synagogue, hospital, school, barracks, &c. Linen cloth, leather, hardware, and fire-arms are made here; and there is some river navigation. Saarlouis is the birth-place of Marshal Ney, and the house where he was born is marked by a marble tablet. The name of the town, then in the possession of France, was changed to Sarrelibre at the time of the first revolution. It was ceded to Prussia in 1815. Pop. 6340.

SAATZ (Bohem. *Zatecz*, Lat. *Zatecium*), a town of Bohemia, capital of a circle of the same name, on the Eger, here crossed by a suspension-bridge, 40 miles W.N.W. of Prague. It is an ancient, ill-built, and wretched-looking place, containing numerous churches (the principal one a large clumsy building), two convents, schools, a town-hall, and a court-house. There are breweries and manufactories of nails in the town. The hops grown in the vicinity are much esteemed, being considered the best in Bohemia. There is some trade in that article and in corn. Pop. 5554.

SAAVEDRA FAXARDO, DIEGO DE, a Spanish statesman and littérateur, was born of a noble family in the kingdom of Murcia in 1584. After being secretary to Cardinal Borgia, he became ambassador to Rome, and was employed for thirty-four years in numerous negotiations in Italy, Germany, and Switzerland. After being nominated to the supreme council of the Indies in 1646, he subsequently retired to a convent of the Augustinians, where he died in 1648. His works have been collected and published at Antwerp in folio, 1677-78. His most popular production was his *Literary Republic*.

SABARA, a town of Brazil, in the province of Minas Geraes, on the right bank of the Rio das Velhas, 50 miles N.N.W. of Duro Preto. It is a long, dull town, with broad, well-paved streets, lined with handsome houses built generally of earth and roofed with tiles. The public buildings are a court-house, several churches, an hospital, and two schools. In the neighbourhood are some gold-mines; but, notwithstanding, the trade of Sabara is not very great. Pop. about 5000.

SABATIER, ANDRÉ HYACINTHE, a French littérateur, was born at Cavaillon in 1726. He became tutor to the son of the Prince of Soubise, and, after the suppression of the Jesuits, filled the chair of rhetoric at the college of Tournon. He quitted this place after a time and went to Paris, where he obtained a pension from the king. In 1789, he allowed himself to be carried away with the opinions of the day, and he accepted the chair of belles-lettres at the central college of Var. He was subsequently nominated to the central school of Carpentras; but being unable to hold this situation from the violence of the revolution, he retired with his family to Avignon, where he died on the 14th August 1806, aged eighty years.

Sabatier wrote a great number of *Odes* and *Epîtres*, which had some success during their day, but which, it is to be feared, are now mostly forgotten. He addressed also numerous *Discours* to the French people, characterized by judicious observations and useful precepts, but which are now permitted to enjoy the dignified retirement of the

Odes. The most complete edition of his *Œuvres* is that of Avignon, 2 vols. 1779. In the first volume, which is chiefly composed of verse, we may mention an *Epître à l'abbé Poulle sur la méthode de diviser les discours*, and *L'Enthousiasme*, an ode, of which many of the strophes would not be considered unworthy of J. B. Rousseau. The second volume is composed of academical discourses.

SABBATH, in the Hebrew language, signifies *rest*. The seventh day was denominated the *Sabbath*, or *day of rest*, because in it God rested from all his works which he had created. From that time the seventh day seems to have been set apart for religious services; and, in consequence of a particular injunction, it was afterwards observed by the Hebrews as a holiday. They were commanded to set it apart for sacred purposes in honour of the creation, and likewise in memorial of their own redemption from Egyptian bondage.

The importance of the institution may be gathered from the different laws respecting it. When the ten commandments were published from Mount Sinai in tremendous pomp, the law of the Sabbath held a place in what is commonly called the first table; and by subsequent statutes the violation of it was to be punished with death. Six days were allowed for the use and service of man; but the seventh day God reserved to himself, and appointed it to be observed as a stated time for holy offices, and to be spent in the duties of piety and devotion. On this day the ministers of the temple entered upon their week; and those who had attended on the temple service the preceding week went out at the same time. New loaves of shew-bread were placed upon the golden table, and the old ones were taken away. Two lambs were offered for a burnt-offering, together with a certain proportion of fine flour, mingled with oil, for a bread offering, and wine for a libation. The Sabbath, like all other festivals, was celebrated from evening to evening. It began at six in the evening on Friday, and ended at the same time the next day.

Concerning the time at which the Sabbath was first instituted, different opinions have been held. Some have maintained, that the sanctification of the seventh day, mentioned in Genesis ii., is only there spoken of as *δια προlepsιν*, or by anticipation; and is to be understood of the Sabbath afterwards enjoined the children of Israel at the commencement of the Mosaic dispensation. But without entering into a particular examination of all the arguments produced in support of this opinion, a few observations, it is presumed, will be sufficient to show that it rests upon no solid foundation.

It cannot easily be supposed that the inspired penman would have mentioned the sanctification of the seventh day amongst the primeval transactions, if such sanctification had not taken place until 2500 years afterwards. Writers, ambitious of that artificial elegance which the rules of criticism have established, often bring together in their narrative events which were themselves far distant, for the sake of giving form to their discourse; but Moses appears to have despised all such flimsy refinements, and to have constructed his narrative in conformity to the series of events.

From the accounts we have of the religious service practised in the patriarchal age, it appears that, immediately after the fall, when Adam was restored to favour through a Mediator, a stated form of public worship was instituted, which man was required to observe, in testimony, not only of his dependence on the Creator, but also of his faith and hope in the promise made to our first parents, and seen by them afar off. Of an institution, then, so grand and important, no circumstance would be omitted that is necessary to preserve it, or that contributes to render the observance of it regular and solemn.

That determined times are necessary for the due celebra-

Sabbath.

formance.

tion of divine service, cannot be denied. Such is the constitution of man, that he must have particular times set apart for particular services. He is doomed to toil and labour, to earn his bread with the sweat of his brow; and is capable of performing religious duties only in such a manner as is consistent with his situation in the world. If stated times for religious solemnities had not been enjoined, the consequence would have been, that such solemnities would have been altogether neglected; for experience shows, that if mankind were left at liberty when and how often they should perform religious offices, these offices would not be performed at all. It is the observation of holy times that preserves the practice of holy services; and without the frequent and regular returns of hallowed days, man would quickly forget the duty which he owes to God, and in a short time no vestige of religion would be found in the world.

Objections
to the ear-
ly institu-
tion of the
Sabbath
considered.

Among the ordinances which God vouchsafed his ancient people, we find that the pious observation of holidays was particularly insisted upon; and the Sabbath was enjoined to be kept holy, in the most solemn manner, and under the severest penalties. Can it then be supposed that He would suffer mankind, from the creation of the world to the era of Moses, to remain without an institution so expedient in itself, and as well fitted to answer the end proposed by it under the one dispensation, as ever it could be under the other? No. We have every imaginable reason to conclude, that when religious services were enjoined, religious times were appointed also; for the one necessarily implies the other.

It is not an objection to the early institution of the Sabbath that there is no mention of it in the patriarchal age. It would have swelled the Bible to a most enormous size had the sacred historian given a particular account of all the transactions of those times; and, besides, it would have answered no end. When Moses wrote the book of Genesis, it was unnecessary to relate minutely transactions and institutions already well known by tradition. Accordingly we see that his narrative is everywhere very concise, and calculated only to preserve the memory of the most important facts. However, if we take a view of the church-service of the patriarchal age, we shall find that what is called the legal dispensation, at least the liturgic part of it, was no new system, but a collection of institutions observed from the beginning, and republished in form by Moses. The Scriptures inform us that Cain and Abel offered sacrifices; and the account which is given of the acceptance of the one, and the rejection of the other, evidently shows that stated laws respecting the service had then taken place. "In process of time," at the end of the days, "Abel brought an offering." Here was priest, altar, matter of sacrifice, appointed time, motive to sacrifice, and atonement made, and accepted. The distinction of animals into clean and unclean before the Flood, and Noah's sacrifice immediately after his deliverance, without any new direction, is an unanswerable proof of the same truth. It is testified of Abraham, by God himself, that he kept his charge, his commandments, his statutes, and his laws. These expressions comprehend the various branches into which the law given at Sinai was divided. They contain the moral precepts, affirmative and negative, the matter of religious service, a body of laws to direct obedience, and to which man was to conform his conduct in every part of duty. Agreeably to this, we find that sacrifices were offered, altars and places of worship consecrated, and the Sabbath also mentioned as a well-known solemnity, before the promulgation of the law. It is expressly taken notice of at the fall of manna; and the incidental manner in which it is then mentioned is a convincing proof that the Israelites were no strangers to the insti-

tution. For had it been a new one, it must have been enjoined in a positive and particular manner, and the nature of it must have been laid open and explained, otherwise the term would have conveyed no meaning.

The division of time into weeks, or periods of seven days, which obtained so early and almost universally, is a strong indication that one day in seven was always distinguished in a particular manner. *Week*,¹ and *seven days*, are in scripture language synonymous terms. God commanded Noah, seven days before he entered the ark, to introduce into it all sorts of living creatures. When the waters of the Flood began to abate, Noah sent forth a dove, which, finding no rest for the sole of her foot, returned to him. After seven days he sent forth the dove a second time, and again she returned to the ark. At the expiration of other seven days he let go the dove a third time; and a week is spoken of (Gen. xxix.) as a well-known period of time.

This septenary division of time has, from the earliest ages, been uniformly observed over all the eastern world. The Israelites, Assyrians, Egyptians, Indians, Arabians, and Persians, have always made use of a week, consisting of seven days. Many vain attempts have been made to account for this uniformity; but a practice so general and prevalent could never have taken place had not the septenary distribution of time been instituted from the beginning, and handed down by tradition.

From the same source also must the ancient heathens have derived their notions of the sacredness of the seventh day. That they had such notions of it is evident from several passages of the Greek poets quoted by Aristobulus, a learned Jew, by Clement of Alexandria, and Eusebius.

ἑβδομη, ἱερὸν ἡμέρα.
The seventh, the sacred day.

Ἐβδοματὴ δ' ἵππιστα κατηλυθὲν, ἱερὸν ἡμέρα.
Afterwards came the seventh, the sacred day.

Again:

Ἐβδομον ἡμέρην, καὶ τὰ τετελεσται πάντα.
On the seventh day all things were completed.

Ἐβδοματὴ δοὶ τετελεσμένα πάντα τέτυκται.
All things were made perfect on the seventh day.

That they likewise held the number *seven* in very high estimation, has been shown by a learned, though sometimes fanciful author,² with such evidence as to enforce conviction. The Pythagoreans call it the venerable number, *σεβασμὸν ἀξίος*, worthy of veneration, and held it to be perfect and most proper to religion. They denominated it fortune, and also styled it voice, sound, muse, because, no doubt, seven distinct notes comprehend the whole scale of music, beyond which neither voice nor instrument can go, but must return from the seventh, and begin again anew. They likewise designed it *τελεισφόρος*, leading to the end. Seven, in the Hebrew language, is expressed by a word that primarily signifies fulness, completion, sufficiency, and is applied to a week, or seven days, because that was the full time employed in the work of creation; to the Sabbath, because on it all things were completed; and to an oath, because it is sufficient to put an end to all strife. This opening of the Hebrew root will enable us to come at the meaning of those expressions of the heathens, and also let us see whence they derived their ideas and modes of speaking, and that the knowledge of the transactions at the creation, though much perverted, was never entirely lost by them.

It has been supposed by some, that the heathens borrowed the notion of the sacredness of the seventh day from the Jews. But this opinion will not readily be admitted, when it is considered that the Jews were held in the greatest con-

Sabbath.

Argument
from the
general di-
vision of
time into
weeks.

¹ שבוע, *sevuca*.

² Holloway's Originals, vol. ii. p. 60.

Sabbath. tempt by the surrounding nations, who derided them no less for their sabbaths than for their circumcision. All sorts of writers ridiculed them on this account. Seneca charged them with spending the seventh part of their time in sloth. Tacitus said, that not only the seventh day, but also the seventh year, was unprofitably wasted. Juvenal brings forward the same charge; and Persius upbraided them with their *recutita sabbata*. Plutarch said that they kept it in honour of Bacchus; Tacitus affirmed that it was in honour of Saturn; but the most abominable assertion of all is that of Apion, who said that they observed the Sabbath in memory of their being cured on that day of a shameful disease, called by the Egyptians *sabbo*.

Some, perceiving the force of this objection, have contended that time was divided into weeks of seven days, that each of the planetary gods, the Sun, Moon, Mercury, Venus, Mars, Jupiter, and Saturn, who were the *Di majorum gentium*, might have a day appropriated to his service. But if such was the origin of weeks, how came the great and ancient goddess Tellus to be omitted? She was worshipped by the early idolaters as well as the other planets, and must surely have been deemed by them as worthy of a particular day set apart to her honour as the planet Saturn, who was long undiscovered, afterwards seen but occasionally, and at all times considered as of malign aspect.

Strict manner in which the ancient Jews observed the sabbath.

Others have supposed, that as the year was divided into lunar months of something more than twenty-eight days, it was natural to divide the months into quarters from the different phases of the moon, which would produce as many weeks of seven days. But this supposition is less tenable than the former. The phases of the moon are not so precisely marked at the quarters as to attract to them any particular notice; nor are the quarterly appearances of one month commonly like those of another. We cannot, therefore, conceive what should have induced the earliest observers of the phases of the moon to divide the month into four parts rather than into three, or five, or seven. Had the ancient week consisted of fourteen days, it might have been inferred, with some degree of plausibility, that its length was regulated by the phases of the moon, because the shape of that luminary, at the end of the second quarter, is very precisely marked; but there is nothing which, in the present hypothesis, could have everywhere led mankind to make their weeks consist of seven days. This division of time, therefore, can be accounted for only by admitting the primeval institution of the Sabbath, as related by Moses in the book of Genesis. That institution was absolutely necessary to preserve among men a sense of religion; and it was renewed to the Jews at the giving of the law, and its observance enforced by the severest penalties. It was accordingly observed by them with more or less strictness in every part of their commonwealth; and there is none of the institutions of their divine lawgiver which, in their present state of dispersion, they more highly honour. They regard it, indeed, with a superstitious reverence, call it their spouse, their delight, and speak of it in the most magnificent terms. They have often varied in their opinions of the manner in which it ought to be kept. In the time of the Maccabees, they carried their respect for the sabbath so very high, that they would not on that day defend themselves from the attacks of their enemies. But afterwards they did not scruple to stand upon their necessary defence, although they would do nothing to prevent the enemy from carrying on their operations. When our Saviour was on earth, it was no sin to loose a beast from the stall and lead him to water; and if he had chanced to fall into a ditch, they pulled him out. But now it is absolutely unlawful to give a creature in that situation any other assistance than that of food; and if they lead an animal to water, they must take care not to let the bridle or halter hang loose, otherwise they are transgressors.

VOL. XIX.

As the law enjoins rest on that day from all servile employments, in order to comply with the injunction, they undertake no kind of work on Friday but such as can easily be accomplished before evening. In the afternoon they put into proper places the meat that they have prepared to eat the day following. They afterwards set out a table covered with a clean cloth, and place bread upon it, which they also cover with another cloth; and during the sabbath the table is never moved out of its place. About an hour before sunset, the women light the sabbath lamps, which hang in the places where they eat. They then stretch forth their hands to the light, and pronounce the following benediction. "Blessed be thou, O God, king of the world, who hast enjoined us, that are sanctified by thy commandments, to light the sabbath lamp." These lamps are two or more in number, according to the size of the chamber in which they are suspended, and continue to burn during the greater part of the night. In order to begin the sabbath well, they wash their hands and faces, trim their hair, and pair their nails, beginning at the fourth finger, then going to the second, then the fifth, then the third, and ending with the thumb. If a Jew casts the parings of his nails to the ground, he is *rasnah*, that is, a wicked man; for Satan has great power over those parings of nails; and it seems they are of great use to the wizards, who know how to employ them in their enchantments. If he buries them in the earth, he is *zedeh*, that is, a just man; if he burns them in the fire, he is *chesid*, that is, worthy of honour, or an holy man. When they have performed these preparatory ceremonies, they repair to the synagogue, and enter upon their devotions. As soon as prayers begin, the departed souls spring out of the purgatorial flames, and have liberty to cool themselves in water while the sabbath lasts, for which reason the Jews prolong the continuance of it as much as they can; and the rabbin have strictly commanded them not to exhaust all the water on the sabbath day, lest those miserable souls should by these means be deprived of the refreshing element. When they have ended their prayers, they return home, and salute one another, by wishing a good sabbath. They then sit down to table. The master of the family takes a cup full of wine, and lifting up his hand, says, "Blessed be thou, O God our Lord, king of the world, who hast created the fruit of the vine. Blessed be thou, O God our Lord, king of the world, who hast sanctified us by thy commandments, and given us thy holy sabbath; and of thy good will and pleasure hast left it to us an inheritance, the memorial of thy works of creation. For it is the beginning of the congregation of saints, and the memorial of the coming out of Egypt. And thou hast also chosen us from all other people, and sanctified us, and with love and pleasure hast left thy holy sabbath an inheritance. Blessed be thou, O God, who sanctifiest the sabbath." After this benediction is ended, he drinks, and gives the cup to all who are present. He then removes the cloth, and taking bread, says, "Blessed be thou, O God our Lord, king of the world, who bringest bread out of the earth." Then he breaks off a bit, and eats, and also gives a piece of it to every one of the company.

Sabbath. Mode of observing it among the modern Jews.

On the morning of the sabbath, the Jews do not rise so early as they do at other times, thinking, the greater pleasure they take on that day, the more devoutly they keep it. When they come into the synagogue, they pray as usual, only the devotions are somewhat longer, being intermingled with psalmody, in honour of the sabbath. The pentateuch is then produced, and seven sections of it are read in order by seven persons chosen for the purpose. Several lessons are likewise read out of the prophets, which have some relation to what was read out of the law. After morning prayers, they return to their houses, and eat the second sabbath-meal, showing every token of joy, in honour of the festival. But if one has seen any thing ominous in his

4 B

Sabbath.

sleep; if he has dreamed that he burned the book of the law, that a beam has come out of the walls of his house, or that his teeth have fallen out; then he fasts until very late at night, for all such dreams are bad ones. In the afternoon they go again to the synagogue, and perform the evening service, adding to the ordinary prayers some lessons that respect the sabbath. When the devotional duties are ended, they return home, and light a candle resembling a torch, and again sit down to eat. They remain eating until near six, and then the master of the family takes a cup, and pouring wine into it, rehearses some benedictions; after which he pours a little of the wine upon the ground, and says, "Blessed be thou, O Lord, King of the world, who hast created the fruit of the vine." Then holding the cup in his left hand, with the right he takes a box of sweet spices, and says, "Blessed be thou, O Lord God, who hast created various kinds of sweet spices." He smells the spices, and holds them out to the rest, that they may do the same. He then takes the cup in his right hand, and going to the candle views the left very narrowly, and pronounces a blessing. With the cup in the left hand, he examines the right in the same manner. Again, holding the cup in his right hand, he rehearses another benediction, and at the same time pours some of the wine on the ground. After this he drinks a little of it, and then hands it about to the rest of the family, who finish what remains. In this manner the sabbath is ended by the Jews, and they may return to their ordinary employments. Those who meet pay their compliments, by wishing one another a happy week.

Prohibitions observed.

The rabbin have reckoned up thirty-nine primary prohibitions, which ought to be observed on the sabbatical festival; but their circumstances and dependents, which are also obligatory, are almost innumerable. The thirty-nine articles are, not to till the ground, to sow, to reap, to make hay, to bind up sheaves of corn, to thrash, to winnow, to grind, to sift meal, to knead the dough, to bake, to shear, to whiten, to comb or card wool, to spin, to twine or twist, to warp, to dye, to tie, to untie, to sew, to tear or pull in pieces, to build, to pull down, to beat with a hammer, to hunt or fish, to kill a beast, to flay it, to dress it, to scrape the skin, to tan it, to cut leather, to write, to scratch out, to rule paper for writing, to kindle a fire, to extinguish it, to carry a thing from place to place, and to expose any thing to sale. These are the primary prohibitions, and each of them has its proper consequences, which amount to an incredible number; and the Jews themselves say, that if they could keep but two sabbaths as they ought, they would soon be belivered out of all their troubles.

If a Jew on a journey is overtaken by the sabbath in a wood or on the highway, no matter where, nor under what circumstances, he sits down, he will not stir out of the spot. If he falls down in the dirt, he lies there; he will not rise up. A fresh wound must not be bound up on the sabbath day. A plaster that had been formerly applied to a sore may remain on it; but if it falls off, it must not be put on anew. The lame may use a staff, but the blind must not. These particulars, and a great many more of the same nature, are observed by the Jews in the strictest manner. But if any one wishes to know more of the practice of that race, he may consult Buxtorf's *Judaica Synagoga* (chap. x. xi.), where he will find a complete detail of their customs and ceremonies on the sabbath, and likewise see the primary prohibitions branched out into their respective circumstances.

Institution of Sunday, or the Lord's day. As the seventh day was observed by the Jewish church, in memory of the rest of God after the works of creation, and their own deliverance from Pharaoh's tyranny; so the first day of the week has always been observed by the Christian church, in memory of the resurrection of Jesus Christ, by which he completed the work of man's redemp-

tion upon earth, and rescued him from the dominion of him who has the power of death. Sabbath.

This day was denominated by the primitive Christians the Lord's day. It was also sometimes called Sunday, which was the name given to it by the heathens, who dedicated it to the sun. And, indeed, although it was originally called Sunday by the heathens, yet it may very properly retain that name among the Christians, because it is dedicated to the honour of the true light, which lighteth every man that cometh into the world; of Him who is styled by the prophet the Sun of righteousness, and who on this day arose from the dead. But although it was, in the primitive times, indifferently called the Lord's day or Sunday, yet it was never denominated the sabbath; a name constantly appropriated to Saturday, or the seventh day, both by sacred and ecclesiastical writers.

Of the change from the seventh to the first day of the week, or even of the institution of the Lord's day festival, there is no account in the New Testament. However, it may be fairly inferred from it, that the first day of the week was, in the apostolic age, a stated time for public worship. On this day the apostles were assembled, when the Holy Ghost came down so visibly upon them to qualify them for the conversion of the world. On this day we find St Paul preaching at Troas, when the disciples came to break bread; and the directions which the same apostle gives to the Corinthians concerning their contributions for the relief of their suffering brethren, plainly allude to their religious assemblies on the first day of the week. The mention of it in the New Testament accidental.

Thus it would appear from several passages in the New Testament, that the religious observation of the first day of the week is of apostolical appointment; and may indeed be very reasonably supposed to be amongst those directions and instructions which our blessed Lord himself gave to his disciples during the forty days between his resurrection and ascension, in which he conversed with them, and spoke of the things pertaining to the kingdom of God. Still, however, it must be owned that those passages, although the plainest that occur, are not sufficient to prove the apostolical institution of the Lord's day, or even the actual observation of it. In order, therefore, to place the matter beyond all controversy, recourse must be had to ecclesiastical testimony.

From the consentient evidence and uniform practice of the primitive church, and also from the attestation of Pliny, we find that the first day of the week was observed in the earliest ages as a holiday or festival, in honour of the resurrection of Christ. Now there are but two sources whence the custom could possibly have arisen. It must have been instituted either by human or divine authority. But by human authority it was not instituted; for there was no general council in those early times, and without the decree of a general council it was impossible that any ecclesiastical institution could have been universally established at once. It remains, therefore, that it must have been instituted by divine authority; and that it really was so, will further appear from the following considerations. It is certain that the apostles travelled over the greatest part of the world, and planted churches in the remotest parts of it. It is certain also that they were all led by the same spirit; and their desire was, that unity and uniformity should be observed in all the churches which they had founded. It is not therefore surprising that, in the primitive times, the same doctrine, the same worship, the same rites and customs, should prevail all over the Christian world; nay, it would have been unaccountable had the case been otherwise. For this reason we may conclude that every custom, universally observed in the early ages of the Christian church, and not instituted by a general council, was of original appointment. It never-theless appears to be of divine origin.

As the Lord's day is sanctified, that is, set apart, to Chris-

Sabbath. tians for the worship and service of God, their Creator, Redeemer, and Sanctifier, a little consideration will easily discover how it ought to be observed. Although a day separated from worldly business, yet it is in no sense a day of idleness, but a season appropriated to the works of salvation and labours of charity.

How it was observed in the primitive times. In the primitive times this holy day was observed in the most solemn manner. From the monuments of those early ages we learn, that it was spent in a due and constant attendance on all the offices of divine worship. On it they held their religious assemblies, in which the writings of the apostles and prophets were read to the people, and the doctrines of Christianity further pressed upon them by the exhortations of the clergy. Solemn prayers and praises were offered up to God, and hymns sung in honour of Christ; the Lord's supper was constantly celebrated; and collections were made for the maintenance of the clergy and the relief of the poor. On this day they abstained as much as they could from bodily labour. They looked upon it as a day of joy and gladness; and therefore all fasting on it was prohibited, even during the season of Lent, their great annual fast. Such was the zeal of those times, that nothing, no not the severest persecutions, hindered them from celebrating the holy offices on this day. They were often beset and betrayed, and as often slaughtered in consequence of cruel edicts from emperors, those very emperors for whose happiness and prosperity they always offered up their fervent prayers. For this cause, when they could not meet in the day-time, they assembled in the morning before it was light; and when sick, in exile, or in prison, nothing troubled them more than that they could not attend the service of the church. No trivial pretences were then admitted for any one's absence from public worship; for severe censures were passed upon all who were absent without some urgent necessity. When the empire became Christian, Constantine and his successors made laws for the more solemn observation of the Lord's day. They prohibited all prosecutions and pleadings, and other juridical matters, to be transacted on it, and also all unnecessary labour; not that it was looked upon as a Jewish sabbath, but because these things were considered as inconsistent with the duties of the festival.

But although the primitive Christians did not indulge themselves in the practice of unnecessary labour or trifling amusements, yet they did not wholly abstain from working, if great necessity required it. The council of Laodicea enjoined that men should abstain from work on the Lord's day if possible; but if any were found to Judaize, they were to be censured as great transgressors. So circumspect were the primitive Christians about their conduct on this festival, that on the one hand they avoided all things which tended to profane it, whilst on the other they censured all those who insisted that it should be observed with Pharisaical rigour and devotion.

Advantages resulting from the observation of it. The primary duty of the Lord's day is public worship. The nature and design of the Christian religion sufficiently shows the necessity and importance of assembling for the duties of devotion. The whole scope of Christianity is to bring us to an union with God, which cannot be obtained or preserved without frequent communications with him; and the reasons which show religious intercourse to be the indispensable duty of Christians in a private capacity, will bind it with equal or more force on them considered as a community.

The advantages of public worship, when duly performed, are many and great. There are two, however, which deserve to be considered in a particular manner. It gives Christians an opportunity of openly professing their faith, and testifying their obedience to their Redeemer in the wisest and best manner; and in an age when infidelity has arisen to an alarming height, when the Son of God is crucified afresh, and put to open shame, every man, who has

any regard for religion, will cheerfully embrace all opportunities of declaring his abhorrence of the vicious courses pursued by those apostates. He will lay hold with pleasure on every occasion to testify that he is neither afraid nor ashamed to confess the truth; and will think it his indispensable duty openly to disavow the sins of others, that he may not incur the guilt of partaking of them.

Public worship preserves in the minds of men a sense of religion, without which society cannot exist. Nothing can keep a body of men together, and unite them in promoting the public good, but such principles of action as may reach and govern the heart. But these can be derived only from a sense of religious duties, which can never be so strongly impressed upon the mind as by a constant attendance upon public worship. Nothing can be more weak than to neglect the public worship of God, under the pretence that we can employ ourselves as acceptably to our Maker at home in our closets. Both kinds of worship are indeed necessary; but one debt cannot be paid by the discharge of another. By public worship every man professes his belief in that God whom he adores, and appeals to Him for his sincerity, of which his neighbour cannot judge. By this appeal he endears himself more or less to others. It creates confidence; and it roots in the heart benevolence, and all other Christian virtues, which produce, in common life, the fruits of mutual love and general peace.

SABBIONETTA, a town of Austrian Italy, Lombardy, in the province and 18 miles S.W. of Mantua, near the left bank of the Po. Anciently a place of much importance, it has now fallen to a low position, and is only remarkable for some public buildings, an old palace, now the court-house, and several churches.

SABELLIUS, an ecclesiastic, who flourished in the second century at Ptolemais in Pentapolis, was the author of the heretical system of Sabellianism. According to that creed, there existed in the ages of eternity one God, in one person, absolute, solitary, and inactive. At the beginning of time it occurred to him to create beings who should delight and glorify him. In order to do this, he found it necessary to assume, in addition to his own innate character, other two characters, impersonations, or *persons*. According to the *Logos*, he created men after his own image; and as the Holy Spirit, he endowed them with wisdom. These two impersonations continued to act in a limited manner during the whole period before the Christian era. At the end of that period, they took a wider range. The *Logos* appropriating a human body, and by that appropriation creating the person of Christ, removed the guilt of men, and became their permanent intercessor. The Holy Spirit, in virtue of that removal and intercession began to act with greater facility upon sinful souls. Their influence is still exerted, and will be exerted until men be redeemed, and be rendered capable of glorifying their Maker. Then will the Father put off the two impersonations, and appear again in his own eternal character as the one absolute God. (See Neander's *Church History*.)

SABINI, an ancient people of Central Italy, were generally supposed to have derived their name from Sabus, their chief tutelary deity. Their antiquity was very great. They were the parent-stock of many of the neighbouring tribes, such as the Samnites, the Peligni, and the Picentes. Of their early descent nothing certain was known. The only plausible genealogy is that which infers, from a similarity of language and religion, that they were a cognate branch with the Umbrians. So completely, indeed, was their origin lost in obscurity that Strabo calls them natives of the soil. The territory of the Sabines was bounded on the S. by Latium, on the E. by the Marsi and Vestini, on the N. by Umbria, and on the W. by Umbria and Etruria. It was very broken and rugged. The eastern part was occupied with the barren ranges and offshoots of the Apen-

d'Olonne.

nines. The western part, though arable, sloped away in considerable undulations towards the valley of the Tiber. A country of such highland nature had an effect upon the character of the Sabines. The mountain air and exercise made them healthy, strong, and hardy. Their want of all luxuries preserved them from weakness and effeminacy. The religious superstitions which were fostered by the wild and weird phenomena of their homes heightened their valour to the pitch of enthusiasm. They were indeed men who were ready to dare and able to accomplish the conquering of inroads upon their neighbours' territories. Accordingly, at an early age of authentic history, the Sabines, issuing from the north-eastern uplands to which they were originally confined, began a system of warlike aggression. Gradually, and by repeated attacks, their invading hordes subdued the aborigines, and advanced southward, occupying the land. At length, pushing their outposts to the very gates of Rome, they commenced to interfere with the affairs of the rising city. By victory or by compromise they gained admittance into the state upon very advantageous terms. The Quirinal Hill was allotted for their residence; a share in the government was given to them; and their sacerdotal and religious institutions were adopted by the whole body of the people. Nor did this important acquisition satisfy the ambition of the rest of the Sabine nation. They persisted in their encroachments upon the Roman territory. The defeats they received from Tullus Hostilius and from Tarquinius Priscus only checked them for a time. Their system of predatory raids was resumed, and was not discontinued till 449 B.C. The power of the Sabines then began to be broken. In that year M. Horatius gave them a defeat which stilled their animosity for more than a century and a half. They recovered in 290 B.C., only to be overthrown by Manlius Curius Dentatus with greater completeness than ever. Their nationality had received its death-blow. Not more than twenty years had elapsed before the Roman right of suffrage was conferred upon them, and they were absorbed into the commonwealth of Rome.

SABINUS, GEORGE, a Latin poet, born in the electorate of Brandenburg in 1508. His poem *Res Gestæ Cæsarum Germanorum* spread his reputation all over Germany, and procured him extensive patronage. He was made professor of the belles lettres at Frankfurt-on-the-Oder, rector of the new academy of Königsberg, and counsellor to the Elector of Brandenburg. He married two wives, the first of whom was the eldest daughter of Melancthon, and died in 1560. His poems are well known, and have often been printed.

SABLÉ, a town of France, in the department and on the right bank of the Sarthe, at its confluence with the Erve, 27 miles W.S.W. of Le Mans. It is a beautiful town, almost encircled by the river, which is spanned by a bridge of black marble. Sablé was formerly strongly fortified, but the defences have been all destroyed. On a height above the town stands a splendid mansion built upon the site of an old castle. Gloves, hats, serge, &c., are made here; and marble is quarried in the vicinity. There is some trade in corn, fruit, and marble. Pop. 5282.

SABLES D'OLONNE, LES, a town of France, capital of an arrondissement in the department of Vendée, on a peninsula on the coast of the Atlantic, 20 miles S.S.W. of Napoleon (formerly Bourbon) Vendée. Part of its site consists of level ground, hardly raised above the sea; the remainder is slightly elevated in the form of an amphitheatre. Several of the streets are long and handsome. Two churches, a nunnery, alms-houses, schools, hospitals, and a prison are among the establishments of the place. There is a lighthouse, and a harbour capable of accommodating vessels of 200 tons burden. The town is de-

fended towards the sea by a fort and battery; and on the land side by salt marshes and a wall. Pop. (1856) 6133.

SABZAWAR, or SUBZAWAR, a town of Persia, in the province of Khorasan, in a wide plain, 65 miles W. of Nishapoor. It is an old place, and was once the residence of an independent monarch, but was afterwards deserted, and its walls have only recently been rebuilt. It is still a very insignificant place, and has a small bazaar. Pop. 4000.

SACCATOO, or SOCOTO, a kingdom of Soodan, in Central Africa, stretching from about N. Lat. 7. to 13. E. Long. 5. to 15., between the kingdoms of Borneo and Baghirmi on the E., and that of Gando on the W. It occupies the country formerly known as the kingdom of Houssa; but the conquest of this and the adjacent regions by the Fellatas has changed the political relations of the country. This people, who are the most intelligent of all the African races, and who profess the Mohammedan religion, are believed to have originally dwelt in the remote east; but this period is involved in impenetrable darkness; and when they first made their appearance as conquerors they came from the west, apparently from the Senegal. As early as the sixteenth century they were in sufficient numbers on the east side of the Kuara (Niger) to be of some consequence in the civil wars of these countries; and in the early part of the seventeenth century they had formed some settlements as far east as Lake Tsad. But they were too much scattered and disunited to have much power; and they were subject to the native heathen tribes of the country until the beginning of the present century. Othman, or Danfodio, one of the Fellata chieftains, who exercised the office of imam at a village near Wurno, succeeded in inspiring his countrymen with a fresh religious impulse, and marshalled them under his colours for a crusade against the unbelievers. Though at first defeated in almost every encounter, yet the warlike spirit of fanaticism grew so high that Othman obtained for himself an extensive empire. This he divided, on his death in 1816, into two parts, Gando and Saccatoo; the former he left to his brother Abd Allahi, the latter to his son Mohammed Bello. This sultan, one of the most distinguished rulers in Soodan, overcame the dangers that threatened his throne from the subject native tribe and the rivalry of surrounding potentates, and endeavoured to introduce order into his dominions. He was succeeded in 1832 by his brother Atiku, under whom the prosperous state of the country continued; but in the reign of his nephew and successor Aliu, the present monarch, who ascended the throne in 1837, great internal disturbance took place, which the weakness of the government was unable to quell, and which brought the country into a wretched condition. It is true that the kingdom includes, with one exception, the same number of provinces as in its most thriving condition, but the revenue has much fallen off, and the provinces have so loose a connection with one another as to be virtually almost independent states. The greater part of the kingdom of Saccatoo lies in the obtuse angle between the Kuara (Niger) flowing from the N.W., and its affluent the Benue or Tchadda from the east. The former river does not touch the country at all, but flows at some distance nearly parallel to its frontier; the latter forms part of its southern boundary, and in the upper part of its course flows through the province of Adamana, which, however, may be almost regarded as an independent kingdom. The greater part of the country is watered by tributaries of the Kuara, the chief of which is the Rima or Kebbi, in the N.W. of the kingdom. In the N.E. portion, however, there are many rivers which belong to the basin of Lake Tsad. The province which contains Saccatoo and Wurno, the principal town, lies in the N.W. extremity

Sabzawar
||
Saccatoo.

Sacchetti
||
Sacchi.

of the country, and is composed of portions of two once very extensive provinces, Kebbi and Sanfara. In it is a small desert tract called Gundumi. Katsena, which lies farther to the S.E., is one of the finest regions in the whole of Soodan. It occupies the watershed between the Niger and Lake Tsad, and consists of an undulating hilly country, with innumerable small rivers. The air is salubrious. Pop. about 300,000. Kano, which lies to the E. of this province, includes a large extent of extremely fertile country, and has a population of more than 400,000, about half of them slaves. Industry and trade are in a flourishing condition here. Still farther east lie the provinces of Katagum, Schera, and Messau, which are in no way remarkable. The provinces already named occupy the whole northern part of the kingdom. To the south of them lie the extensive provinces of Segseg and Bautschi. The former is an exceedingly fertile country, covered with luxuriant corn-fields and meadows of the richest green, variegated with pleasant hills and valleys. Rice is produced here in great abundance. Adamana, the most easterly of all the provinces, is almost an independent state, and is nearly isolated from the rest of the kingdom by the surrounding tribes. Part of this province is mountainous, and still occupied by the native heathens, the Mohammedan conquerors having only a few detached settlements in the country. The residence of the sultan of Saccatoo is at Wurno, but the official capital is the neighbouring town of Saccatoo, on the left bank of the Rima. It was founded in 1803 by Othman, the original conqueror of the country, and is surrounded with walls from 20 to 30 feet high. Entrance is afforded by eight gates, which are closed at sunset. The streets are pretty regularly laid out; and the town contains two large mosques, one of which is 800 feet long, richly adorned and supported by wooden pillars. There is also an extensive palace and a bazaar. The surrounding country is flat and marshy, but of much fertility; and the river abounds in fish. Saccatoo has important manufactures of leather, hardware, and cotton fabrics. The trade is also very extensive; and it is said that British exchequer bills are current here. Large caravans of salt arrive annually from among the Tuarks of the Sahara. It was at Saccatoo that the unfortunate traveller Clapperton died, April 13, 1827. Pop. from 20,000 to 22,000.

SACCHETTI, FRANCO, an eminent Italian novelist, was born at Florence about 1335. The birth and influence of his family gave him a high standing in the republic. His whole life was engrossed with the duties of several important municipal offices. He was in succession one of the Council of Eight, and *podesta* at Bibbiena, at San Miniato, and at Faenza. Yet Sacchetti devoted his leisure hours to the composition of a series of excellent tales. The incidents which he chose were short and simple. His language was a model of classical purity. Many of his references to men and manners had an historical value. The whole series was executed with so much taste and skill that, next to the *Decameron* of Boccaccio, it was reckoned by critics the finest collection of tales in Italian literature. Sacchetti died about 1410. His tales were first printed by Bottari in 1724.

SACCHI, ANDREA, one of the greatest painters of the Roman school, was born near Rome about 1600, and studied under Albani. He pursued his art with the most careful assiduity. The works of Raphael were the subject of his constant contemplations. His own ideas were allowed to lie long and ripen in his imagination. "It was better," he said, "to produce a few masterpieces than a great many mediocre pictures." And when he took up the brush, he painted like one who brought all his powers into play. His composition was simple and natural; his figures were easy and dignified; and his colouring was sober and harmonious. The result of this thorough system of study

was, that Sacchi, at his death in 1661, left behind him several pictures of first-rate excellence. They still call forth the admiration of visitors at Rome. "St Romualdo surrounded by his Monks," in the museum of the Vatican, is reckoned one of the four best paintings in the city. The pictures from the life of the Baptist in St John Lateran, the "Death of St Anna" in S. Carlo di Catinari, a "Crucifixion" in S. Maria sopra Minerva, "St Gregory the Great," in the Vatican museum, and the "Intoxication of Noah," in Palazzo Sciarra, are also very beautiful. (See Lanzi's *History of Painting*, &c.)

SACCHINI, ANTONIO MARIA GASPARO, a very eminent composer of the Neapolitan school, was born at Pozzuoli on the 23d of July 1734, and not at Naples on 13th May 1735, as most of his biographers have stated. He was the son of a poor fisherman, and was destined for the same occupation. Durante, then at the head of the Conservatorio of Sant' Onofrio at Naples, happening accidentally to hear the boy Sacchini singing some popular airs, was so much pleased with his natural talent and intelligence as to ask his parents to give him up to be regularly instructed in music. Sacchini accordingly entered the Conservatory, and there learned the elements of music, and became a good violinist. He then studied musical composition under Durante, who looked upon him as the most promising of his pupils, although Piccini and Guglielmi, older than he, were his fellow-students. Soon after the death of Durante, in 1755, Sacchini quitted the Conservatory, and began to teach singing and to compose operas. In 1762 he was called to Rome to compose a serious opera, which was so well received that he resided chiefly at Rome for the next seven years, during which time he visited several other towns in Italy, in order to compose for them serious and comic operas. The great merit of his opera *Alessandro nell' Indie*, performed at Venice in 1768, obtained for him there the directorship of the Conservatory of L'Ospedaletto. He wrote much beautiful music for convents and churches while he occupied that post for a few years. Doctor Burney met him at Venice in 1770, and heard a *Salve Regina*, of which he speaks very highly in his *Tour*, p. 143. Although then only thirty-six years of age, Sacchini had composed forty serious and ten comic operas, and possessed a high reputation. In 1771 he visited Germany and Holland, and composed two operas for Munich and Stuttgart. He arrived at London in April 1772, and brought out, at first, some of his old operas. Dr Burney says (*History of Music*, vol. iv., p. 498) that Sacchini's first opera for the English stage, *Il Cid*, came out in January 1773, and in May his *Tamerlano*. In November 1773 his *Lucio Vero*, and in the spring of 1774 his *Nitetti* and *Perseo*; his *Montezuma* and *Il Creso* in 1775; *Erifile* in 1776; *L'Amor Soldato* in 1777; *Il Calandrino* in 1778; *Enea e Lavina* in 1779. According to Dr Burney, who knew Sacchini intimately, the musical partizans of other composers immediately raised violent cabals against Sacchini when he first came to London; although his great merits were afterwards amply acknowledged. Unfortunately, Sacchini was thoughtless, dissipated, and extravagant, and was obliged to fly from his creditors in the summer of 1781, and take refuge in Paris. In Madame D'Arblay's *Diary*, vol. ii., p. 75, under the date July 16, 1781, we find a very melancholy portrait of Sacchini, then in London, ruined and miserable. In 1782 he returned to London, but only to get into greater difficulties. He finally left England in 1784, and settled in Paris, where his latter days were rendered more comfortable by a pension from the Queen of France, and also the theatrical pension. In Paris he composed his operas, *Renaud*, *Chimène*, *Dardanus*, and *Cedipe*; the latter a masterpiece in every respect. But even in Paris hostile jealousy pursued him. His health failed; and a severe attack of gout caused his death on the 7th October

Sacchini.

Sacheverell 1786.

Sack.

He was honoured with a public funeral and great marks of respect, which were certainly due to his extraordinary abilities, if not to his prudent conduct. Immediately after his funeral his friend and rival Piccini published a letter, in which his praises of Sacchini's musical powers did equal credit to his head and heart. How very rare are such noble tributes from rival musicians! The merits of Sacchini were very great. He was a perfect musician. His style was always free, graceful, and unconstrained in every kind of composition. His command of musical language embraced the grand, the serious, the comic, the pathetic, with equal ease. His influence upon the progress of his art is now too much lost sight of; but is known to those who have studied his works, and compared them with the works of his contemporaries and successors. Mozart, in his operatic music, was much indebted to Sacchini. There is a bust of Sacchini in the Pantheon chapel at Rome. Besides many of his compositions not published, his works include 16 pieces of church music; 5 oratorios; 38 operas; 6 trios for violins and bass; 6 quartets for violins, viola, and bass; 6 sonatas for the harpsichord, with violin accompaniment.

(G. F. G.)

SACHEVERELL, DR HENRY, a famous Tory clergyman in the reign of Queen Anne, who distinguished himself by indecent and scurrilous sermons and writings against the dissenters and revolution principles. He was born in 1672, and was educated at Magdalen College, Oxford, where he was chamber-fellow with Addison, and where he seems to have cultivated the muses. He became a fellow of his college; took his degree of M.A. in 1696, of B.D. in 1707, and of D.D. in 1708. He owed his consequence, however, to being indiscreetly prosecuted by the House of Lords for his assize-sermon at Derby, and his 5th of November sermon at St Paul's in 1709, in which he asserted the doctrine of non-resistance to government in its utmost extent, and reflected severely on the Act of Toleration. The High and Low Church parties were very violent at that time; and the trial of Sacheverell inflamed the High Church party to dangerous riots and excesses. He was, however, suspended for three years, and his sermons were burned by the common hangman. The Tories being in administration when Sacheverell's suspension expired, he was freed with every circumstance of honour and public rejoicing; was ordered to preach before the Commons on the 29th of May; had the thanks of the House for his discourse; and obtained the valuable rectory of St Andrews, Holborn. He was evidently a very weak, vain, and selfish man, and was subsequently as notorious for his lawsuits with his parishioners as he had been for his quarrels with the state in the earlier part of his career. He died in 1724.

SACHS, HANS, a German *meister-singer* of the time of the Reformation, was born at Nuremberg in 1494, and was bred to the trade of a shoemaker. His mind was ingenious and unweariedly active. While plying the awl he was constantly manufacturing verses. The books of Scripture, the sentiments of the Reformers, and the tales and history in classical literature were taken indiscriminately as the raw material for his rhyming fabrics. His brain continued for many years to produce piece after piece with all the regularity and despatch of a machine. Accordingly, at his death in 1576 his compositions amounted to upwards of six thousand, a portion of which were published at Nurnberg in 5 vols. folio, 1576-79.

SACK (Fr. *vin sec* and *vin d'Espagne*), a species of wine used by our ancestors, regarding the peculiarity of which there have been various conjectures. It is generally supposed to have been a Spanish wine of the dry kind, while some have conceived it to be Rhenish and some Canary. Venner says of sack in 1628 that, "taken by itself, it is very hot and very penetrative; being taken with sugar, the heat is somewhat allayed, and the penetrative quality thereof

also retarded." This statement has led some to imagine that sack was not a sweet wine, from the fact of its being occasionally taken with sugar. At a later period, however, when Falstaff spoke of it as *sherris sack* (properly *Xeres sack*, according to Blount in his *Glossographia*), the word seems to have been used as a general name for all sorts of sweet wines. In contradistinction to the French derivation of the term from the word *sec*, it has been conjectured to be derived from the Spanish *sac*,—a bag in which it was transported from place to place.

SACKVILLE, THOMAS, Lord Buckhurst and Earl of Dorset, a statesman and poet, the son of Richard Sackville of Buckhurst, in the parish of Withiam in Sussex, was born in the year 1536. He was sent to Hart Hall, Oxford, in the latter end of the reign of Edward VI., whence he removed to Cambridge, where he took the degree of Master of Arts. He applied himself to the study of the law in the Inner Temple, and was called to the bar. We are told that he cultivated poetry whilst at the universities, and that these juvenile productions were much admired, though none of them have been preserved. In the fourth and fifth years of Queen Mary we find him a member of the House of Commons, about which time, in 1557, he wrote a poetical piece, entitled the *Induction, or the Mirror of Magistrates*. This last was meant to comprehend all the unfortunate great from the beginning of our history; but the design being dropped, it was inserted in the body of the work. The *Mirror of Magistrates* is formed upon a dramatic plan, in which the persons are introduced speaking. The *Induction* is written much in the style of Spencer, who, with some probability, is supposed to have imitated this author.

In the year 1561 the tragedy of *Ferrex and Porrex*, subsequently called *Gorboduc*, was acted before Queen Elizabeth by the gentlemen of the Inner Temple. This was the first tolerable tragedy in our language. The *Companion to the Playhouse* tells us that the first three acts were written by Mr Thomas Norton. Sir Philip Sidney, in his *Apology for Poetry*, says, "it is full of stately speeches and well-sounding phrases, climbing to the height of Seneca in his style." Rymer speaks highly in its commendation. Spence, at the instigation of Pope, republished it in 1736 with a pompous preface. It is said to be our first dramatic piece written in verse. In the first Parliament of this reign Mr Sackville was member for Sussex, and for Buckinghamshire in the second. In the meantime he made the tour of France and Italy; and in 1566 was imprisoned at Rome, when he was informed of his father's death, by which he became possessed of a very considerable fortune. Having now obtained his liberty, he returned to England, where he was knighted, and afterwards created Lord Buckhurst. In 1570 he was sent as ambassador to France. In 1586 he was one of the commissioners appointed to try the unfortunate Mary, Queen of Scots, and was the messenger employed to report the confirmation of her sentence, as well as to see it executed. The year following he went as ambassador to the States-General in consequence of their complaint against the Earl of Leicester, who, disliking his impartiality, prevailed on the queen to recall him, and confine him to his house. In this state of restraint he continued about ten months, when Leicester dying, he was restored to favour, and in 1580 was installed knight of the Garter. But the most incontrovertible proof of the queen's partiality for Lord Buckhurst appeared in the year 1591, when she caused him to be elected chancellor in the university of Oxford, in opposition to her favourite Essex. In 1598, on the death of the treasurer Burghley, Lord Buckhurst succeeded him, and by virtue of his office became in effect prime minister; and when in 1601 the Earls of Essex and Southampton were brought to trial, he sat as lord high steward on that awful occasion. On the accession of James I. he was graciously received, had the office

Sackville.

of lord high treasurer confirmed to him for life, and was created Earl of Dorset. He continued high in favour with the king till the day of his death, which happened suddenly on the 19th of April 1608, in the council-chamber at Whitehall. He was interred with great solemnity in Westminster Abbey.

SACKVILLE, *Charles*, Lord Buckhurst and Earl of Dorset, a poet and wit, was born on the 24th of January 1637-8. After receiving a private education, he visited Italy; and returning to England shortly before the Restoration, sat in Parliament for East Grimstead in Sussex. Being of wild and dissolute habits, he became a great favourite of Charles II., and did not choose to engage in any public employment. He attended the Duke of York as a volunteer in the Dutch war of 1665, and is said to have composed the celebrated song, "To all you ladies now at land," on the eve of the 3d of June, when the Dutch were defeated, and Opham, their admiral, slain. Buckhurst was soon after made a gentleman of the bed-chamber, and sent a short embassy to France on one of those missions, which was, according to Dryden, "a sleeveless errand." Charles II. had become enamoured of Nell Gwyn, with whom Buckhurst was then living, and this little journey to France was contrived, by the king to get rid of his rival. In 1674 he became heir to the estate and title of his maternal uncle, the Earl of Middlesex; and in 1677, by the death of his father, he inherited the title of Earl of Dorset and the whole of the family estates. He buried his first wife in 1684, and subsequently married a daughter of the Earl of Northampton, a woman of beauty and superior mind, who may still be seen among the Kneller beauties at Hampton Court. Dorset was taken favourable notice of by James II., but ceased to adhere to his policy on his becoming more violent in his measures. On the accession of King William III. he was made lord chamberlain of the household, and received the honour of the Garter. His health afterwards declining, he died at Bath on the 29th January 1705-6.

The epitaph of Dorset was written by Pope; Dryden penned dedications and fulsome panegyrics to him; and Prior eulogized his excellencies in the most elaborate manner. He was distinguished among his contemporaries for his elegant manners, sprightly wit, and courtly address; and his bounty to the learned may be judged of by the number of dedications which were addressed to "the witty Earl." His poetical pieces are, according to Johnson, "the effusions of a man of wit,—gay, vigorous, and airy." (Johnson's *Lives of the Poets*, by Cunningham.)

SACRAMENT, is derived from the Latin word *sacramentum*, which signifies an oath, particularly the oath taken by soldiers to be true to their country and their general. The words of this oath, according to Polybius, were *obtemperaturus sum et facturus quicquid mandabitur ab imperatoribus juxta vires*. The word was adopted by the writers of the Latin Church, and employed to denote those ordinances of religion by which Christians came under an obligation, equally sacred with that of an oath, to observe their part of the covenant of grace, and in which they had the assurance of Christ that he would fulfil his part of the same covenant.

Of sacraments, in this sense of the word, Protestant churches admit but of two; and it is not easy to conceive how a greater number can be made out from Scripture, if the definition of a sacrament be just which is given by the Church of England. By that church the meaning of the word sacrament is declared to be "an outward and visible sign of an inward and spiritual grace given unto us, ordained by Christ himself as a means whereby we receive the same, and a pledge to assure us thereof." According to this definition, baptism and the Lord's Supper are certainly sacraments; for each consists of an outward and visible sign of what is believed to be an inward and spiritual grace; both were ordained by Christ himself; and by the

reception of each does the Christian come under a solemn obligation to be true to his Divine master, according to the terms of the covenant of grace. The Roman Catholics, however, add to this number confirmation, penance, extreme unction, ordination, and marriage; in all, seven sacraments. They call the eucharist, by way of eminence, the Holy Sacrament. Thus to expose the holy sacrament, is to lay the consecrated host on the altar to be adored. The procession of the holy sacrament is that in which this host is carried about the church, or about a town.

SACRAMENTO, a river of the United States of North America, in California, rises in a chain of mountains connecting the Sierra Nevada with the coast range, and flows generally southwards, uniting with the San Joaquin from the south, at the head of Suisoon Bay, through which their united waters are discharged into the Pacific. Its whole length is about 370 miles, for 200 of which it is navigable. It abounds in fish, the catching of which is here an important branch of industry. The valley watered by the Sacramento is one of the most beautiful and fertile portions of California.

SACRAMENTO CITY, the capital of the state of California, on the left bank of the river of the same name, about 150 miles above San Francisco. It owes its origin entirely to the gold discovered here, and was founded in 1849, since which time it has risen to be a large and flourishing town. It is regularly laid out; the streets cross each other at right angles, and are distinguished by numbers and the letters of the alphabet. Many of them are lined with large oak and sycamore trees, which have a very fine effect. Until recently it was very liable to inundations, but the river has been confined to its channel by embankments. The houses, which were formerly of wood, often suffered from fire; but they are now built of more substantial materials. In and about the town are many very beautiful gardens. Among the most conspicuous buildings are numerous churches, hotels, steam-mills, and manufactories. The commercial importance of Sacramento is very great, it being the chief emporium for supplying provisions to the gold regions. Steamers ply regularly between this and San Francisco. Pop. estimated at 20,000.

SACRED, something holy, or that is solemnly offered and consecrated to God by prayers and benedictions. Kings, prelates, and priests are reckoned sacred persons; abbots are only blessed. The deaconhood, sub-deaconhood, and priesthood, are all sacred orders, and are said to impress an indelible character. The custom of consecrating kings with holy oil is derived, says Guttingius, from the Hebrews, amongst whom, he agrees with Grotius, it was never used but to kings who had not an evident right by succession. He adds that the Christian emperors never used it before Justin the younger. This term was first added to the title of Majesty, in designating the English sovereigns, on the accession of James I. in 1603.

SACRIFICE, an offering made to the object of religious worship, is one of the forms of religious cultus everywhere met with, being co-extensive with religion itself. The offerings made have been various, and the forms under which they have been presented have also varied. The offerings for the most part have been the fruit of the field and of the flock; but not unfrequently the tiller of the field and the keeper of the flock have also been offered in sacrifice. The forms in which they have been presented embrace the natural form, or that form transmuted by slaughtering and burning. The selection of the sacrifice appears to have been made upon the ground of its nearness of relation and preciousness to the offerer: it must be his own, the first and the best of its kind; it must represent him,—must be therefore what he values and loves. And as the sacrifice not only represented the offerer, but represented what was his deepest feeling on the occasion of the offering, this

Sacrilege
||
Sacy.

ground of nearness and preciousness furnished different offerings on different occasions. The idea present in and underlying all the forms of presentation appears to be that of bringing the sacrifice near to the object of worship. Another peculiarity of a sacrifice consisted in destroying, in whole or in part, the offering presented to the object of worship. Sacrifices prevailed throughout the whole of the ancient world, both Jewish and Gentile. Christians believe them to have been entirely abolished by the death of Christ. The precise significance of Christ's death has, however, been variously interpreted by different men, and there exists upon the various sides of this important question a large amount of theological literature.

SACRILEGE, **SACRILEGIUM**, the crime of profaning sacred things, or things devoted to God; or of alienating to laymen, for common purposes, what was given to religious persons and pious uses.

SACRO-BOSCO, **JOHANNES DE**. See **ARITHMETIC**, *History of*.

SACY, **ANTOINE ISAAC SILVESTRE DE**, a celebrated orientalist, was born at Paris on the 21st September 1758. Although a delicate boy, he soon became a precocious linguist. His ready mind, under the direction of a private tutor, speedily mastered Latin and Greek. He then applied himself to other languages. Hebrew, Syriac, Chaldee, Samaritan, Arabic, and Ethiopic were acquired in succession; Italian, Spanish, English, and German were added; and at the age of twenty-three he appeared before the public as a prodigy in philology. It was not long before Sacy directed his attention to the history and antiquities of the East. As his studies advanced he continued to lay their results before the learned world. Two memoirs, one on the bursting of the dike of Irem in Arabia Felix, and another on the origin of Arabian literature, were published in the *Recueil de l'Académie des Inscriptions*. Numerous papers on ancient Persian and Arabic history were contributed to the collection entitled *Notices et Extraits des Manuscrits*. He also read before the academy several memoirs on the antiquities of Persia, and especially on the inscriptions found among the ruins of Persepolis. Nor did the turmoil of the Revolution interrupt his engrossing pursuits. He retired to a small country house in the neighbourhood of Paris, and divided his time between the cultivation of his garden and the investigation of the religious system of the Druses. After the revolutionary period the efforts of Sacy for the promotion of oriental learning took a most practical turn. Much of his earnest attention was given to the duties of professor of Arabic and Persian, to which he had been appointed. No less than fifteen years were engrossed in the composition of an Arabic Grammar. He exerted himself to found the Asiatic Society of Paris, a service which was acknowledged by his being made its first president. At the same time, his pen was not slow in advancing the great work of his life. He was a powerful supporter of the *Magasin Encyclopédique* and of the *Mines de l'Orient*; and among other works he published a collection of Arabic extracts entitled *Chrestomathie Arabe*, 1806; the Arabic text of the fables of Pilpay, under the name of *Calila et Dimna*, 1816; the *Pend-Nameh* (Book of Counsels) in Persian and French, 1819; and the *Sessions of Hariri*, in Arabic, 1822. Towards the close of his life Sacy held a very high position. In the class-room no professor could be more eminent. His information was profound, well-arranged, and ready at command. He explained with precision, clearness, and force. So astonishing, indeed, were his qualifications for teaching that old men, who had themselves written and spoken on the subject, came from all parts to sit at his feet. Nor was it only in his lecture-room that he was esteemed. After the death of Cuvier the French held him up as their great champion in learning. He was universally acknowledged

Sacy
||
Sadducees.

to be the greatest living authority in his own particular branch of study. The influence of his commanding intellect was felt throughout the learned world. Chairs of Chinese, Sanscrit, and Hindustanee were established in Paris by his advice. Russian and Prussian institutions for oriental studies were founded under his direction. His pupils filled the principal professorships in Europe; and he had his readers and correspondents in every country. Sacy fell down dead in the street, in a fit of apoplexy, on the 19th of February 1838. At his death he was a peer of France, keeper of the oriental manuscripts in the king's library, and perpetual secretary to the Academy of Inscriptions. His friend Renaud pronounced his eulogy, which was afterwards published under the title of *Notice Historique et Littéraire sur M. le Baron de Sacy*.

SACY, the name by which *Louis Isaac le Maistre* was commonly known. He was born in Paris in 1613, and was educated for the church. The instructions of his uncle, the great Arnauld, and of his spiritual guide, the Abbé of Saint Cyran, made him a zealous Jansenist. Withdrawing in the company of those of the same mind to the famous suburban retreat of Port-Royal-des-Champs, he commenced a life of opposition to the errors and vices of the Jesuits. For several years he assisted his fellow-recluses in instilling their opinions into a small number of pupils, and in composing works for the better enlightenment of their age. Persecution assailed him in 1661, but his zeal remained unabated. Fleeting before his enemies, he became an outcast for his principles. Till 1666 there was no other hiding-place for him but the dingy recesses of the Faubourg Saint Antoine. For the following three years his studies were prosecuted in a cell of the Bastille. Even after his liberation the attacks of his enemies did not cease. He returned to Port-Royal in 1675, only to be chased from it in 1679. Weary and worn-out, he retired to the house of his cousin, the Marquis of Pomponne, and died there in 1684. The following is a list of the principal works of Sacy:—*Enluminures du Fameux Almanach des Jésuites intitulé la Déroute et la Confusion des Jansénistes*, in 8vo, 1654; a French translation of the *De Imitatione Christi*, in 8vo, 1662; a French translation of the New Testament, in 2 vols. 8vo, 1667; and a French translation of the Psalms of David, in 3 vols. 12mo, 1696.

SADDUCEES were a famous sect among the ancient Jews, and consisted of persons of great quality and opulence. Respecting their origin there are various accounts and various opinions. Epiphanius, and after him many other writers, contend that they took their rise from Dositheus, a sectary of Samaria, and derived their name from the Hebrew word צדק, *just* or *justice*, from the great justice and equity which they showed in all their actions; a derivation which neither suits the word Sadducee nor the general character of the sect. They are thought by some, too, to have been Samaritans. But this is by no means probable, as they always attended the worship and sacrifices at Jerusalem, and never at Gerizim.

In the Jewish Talmud we are told that the Sadducees derived their name from Sadoc, and that the sect arose about 260 years before Christ, in the time of Antigonus of Soch, president of the Sanhedrim at Jerusalem, and teacher of the law in the principal divinity school of that city. Antigonus had often in his lectures, it seems, taught his scholars that they ought not to serve God as slaves do their masters, from the hopes of a reward, but merely out of filial love for his own sake; and from this Sadoc and Baithus inferred that there were no rewards at all after this life. They therefore separated from their master, and taught that there was no resurrection nor future state. This new doctrine quickly spread, and gave rise to the sect of Sadducees, which in many respects resembled the Epicureans. Dr Prideaux thinks that the Sadducees were at first no

Sadducees. more than what the Caraites are now; that is, they would not receive the traditions of the elders, but acknowledged the written word only; and the Pharisees being great promoters of those traditions, these two sects hence became directly opposite to each other. Afterwards the Sadducees imbibed other doctrines which rendered them a sect truly impious. They denied the resurrection of the dead, and the existence of angels, and the spirits or souls of men departed. They held that there is no spiritual being but God only; and that as to man, this world is his all. They did not deny but that we had reasonable souls; but they maintained that this soul was mortal, and, by a necessary consequence, they denied the rewards and punishments of another life. They pretended also that what is said of the existence of angels and of a future resurrection is nothing but illusions. St Epiphanius, and after him St Augustin, have advanced that the Sadducees denied the Holy Ghost; but neither Josephus nor the evangelists accuse them of any error like this. It has been also imputed to them that they thought God corporeal, and that they received none of the prophecies. It is difficult to apprehend how they could deny the being of angels, and yet receive the books of Moses, where such frequent mention is made of angels and of their appearances. Grotius and Le Clerc observe that it is very likely they looked upon angels, not as particular beings subsisting of themselves, but as powers, emanations, or qualities, inseparable from the Deity, as the sunbeams are inseparable from the sun. Or perhaps they held angels not to be spiritual, but mortal, just as they thought that substance to be which animates us and thinks in us. The ancients do not tell us how they solved this difficulty, that might be urged against them from so many passages of the Pentateuch, where mention is made of angels. As the Sadducees acknowledged neither punishments nor recompenses in another life, so they were inexorable in chastising the wicked. They observed the law themselves, and caused it to be observed with the utmost rigour by others. They admitted none of the traditions, explications, or modifications of the Pharisees; they kept to the text of the law, and maintained that only what was written was to be observed. The Sadducees are accused of rejecting all the books of Scripture except those of Moses; and to support this opinion, it is observed that our Saviour makes use of no Scripture against them, but passages taken out of the Pentateuch. But Scaliger produces good proofs to vindicate them from this reproach. He observes that they did not appear in Israel till after the number of the holy books was fixed; and that if they had been to choose out of the canonical Scriptures, the Pentateuch was less favourable to them than any other book, since it often makes mention of angels and their apparition. Besides, the Sadducees were present in the Temple, and at other religious assemblies, where the books of the prophets were read indifferently, as well as those of Moses. They were in the chief employments of the nation; many of them even were priests. Would the Jews have suffered in these employments persons that rejected the greater part of their Scriptures? Menasse Ben-Israel says expressly that they did not indeed reject the prophets, but that they explained them in a sense very different from that of the other Jews. Josephus assures us that they denied destiny or fate; alleging that these were only sounds void of sense, and that all the good or evil that happens to us is in consequence of the good or evil side we have taken, by the free choice of our will. They said also that God was far removed from doing or knowing evil, and that man was the absolute master of his own actions. This was roundly to deny a providence; and upon this footing I know not, says

Calmet, what could be the religion of the Sadducees, or what influence they could ascribe to God in things here below. However, it is certain that they were not only tolerated among the Jews, but that they were admitted to the high priesthood itself. John Hircanus, high priest of the nation, separated himself in a signal manner from the sect of the Pharisees, and went over to that of Sadoc. It is said also that he gave strict command to all the Jews, on pain of death, to receive the maxims of this sect. Aristobulus, and Alexander Jannæus, son of Hircanus, continued to favour the Sadducees; and Maimonides assures us, that under the reign of Alexander Jannæus they had in possession all the offices of the Sanhedrim, there only remaining of the party of the Pharisees, Simon the son of Secra. Caiaphas, who condemned Jesus Christ to death, was a Sadducee: as was also Ananus the younger, who put to death St James the brother of our Lord. At this day the Jews hold as heretics the small number of Sadducees which are to be found among them.¹

The sect of the Sadducees was much reduced by the destruction of Jerusalem, and by the dispersion of the Jews; but it afterwards revived. At the beginning of the third century it was so formidable in Egypt that Ammonim, Origen's master, when he saw them propagate their opinions in that country, thought himself obliged to write against them, or rather against the Jews, who tolerated the Sadducees, though they denied the fundamental points of their religion. The Emperor Justinian mentions the Sadducees in one of his novels; banishes them out of all places of his dominions; and condemns them to the severest punishments, as people that maintained atheistical and impious tenets, denying the resurrection and the last judgment. Annus, or Ananus, a disciple of Juda, son of Nachman, a famous rabbi of the eighth century, declared himself, as it is said, in favour of the Sadducees, and strenuously protected them against their adversaries. They had also a celebrated defender in the twelfth century, in the person of Alpharagius, a Spanish rabbi. This doctor wrote against the Pharisees, the declared enemies of the Sadducees, and maintained by his public writings that the purity of Judaism was only to be found among the Sadducees; that the traditions avowed by the Pharisees were useless; and that the ceremonies, which they had multiplied without end, were an insupportable yoke. The rabbi Abraham Ben David Italleri replied to Alpharagius, and supported the sect of the Pharisees by two great arguments,—that of their universality, and that of their antiquity. He proved their antiquity by a continued succession from Adam down to the year 1167; and their universality, because the Pharisees are spread all the world over, and are found in all the synagogues. There are still Sadducees in Africa and in several other places. They deny the immortality of the soul and the resurrection of the body; but they are rarely found, at least there are but few who declare themselves friendly to these opinions.

SADLER, MICHAEL THOMAS, was born at Snelstone, a village in Derbyshire, in January 1780. He was descended, on the father's side, from Sir Ralph Sadler, one of Queen Elizabeth's ministers; and his mother's family had been French refugees at the revocation of the edict of Nantes. He was educated principally at home, his father having intended him for one of the learned professions; but when about eighteen years old he was induced to join his brother in business at Leeds, where he continued until called into public life by the ministerial proposal of the Catholic Relief Bill. On a vacancy occurring for the borough of Newark, in March 1829, Mr Sadler, being invited to become a candidate, immediately complied, and triumphantly

Sadler.

¹ See upon this matter Menasse Ben-Israel, *De Resurrectione Mortuorum*; Basnage's *History of the Jews*; and Calmet's *Dissertation upon the Sects of the Jews, before the Commentary of St Mark*.

Sadler.

carried his election, though opposed by Mr Sergeant Wilde, one of the ablest and most energetic members of the bar. Mr Sadler distinguished himself by a long and eloquent speech delivered against the Roman Catholic claims on the 17th of the same month; and during the continuance of the discussion he was the great champion of the Protestant cause. At the general election of 1830 he was again chosen for Newark; and in 1831 he took his seat for Aldborough in Yorkshire. At the first general election under the Reform Bill, Aldborough having been disfranchised, he became a candidate for the new borough of Leeds; but though highly esteemed by a large number of his townsmen, his reputation as an anti-reformer preponderated over his less equivocal merits, and he lost his election.

In his public career Sadler was generally associated with the old constitutional Tories. To the policy of free trade he was also most decidedly hostile; nor was he less unfriendly to the settlement of the currency question, which he considered should have been effected upon a more equitable adjustment. He was likewise very hostile to the Reform Bill, to which he recorded his objections in a speech when seconding General Gascoigne's motion, the effect of carrying which was the dissolution of Parliament. For Ireland he always expressed the deepest interest, and twice introduced a poor-law bill for that country into Parliament. During the last session he sat in Parliament he was almost constantly occupied in prosecuting the bill he had brought before the legislature for the protection of children employed in the manufactories, and which is familiarly called the Ten Hours Bill. This measure was referred to a select committee, of which Sadler was appointed chairman; and it is believed that the fatigue and responsibility thus imposed on him, of collecting the mass of evidence contained in the report, laid the foundation of his long and fatal illness. Neither, after all, were his efforts successful in passing this measure. Sadler was some years a member of the Royal Society, and author of several works, the most important of which are,—*Ireland, its Evils, and their Remedies*; and *An Essay on the Law of Population*, in two volumes, written principally to controvert the opinions of Malthus. A third volume, intended to complete this treatise, the author was engaged upon at the time of his death, which took place at New Lodge, near Belfast, on the 29th of July 1835. Sadler's disease appears to have been an incurable affection of the heart, brought on by severe study and intense anxiety. At the time of his death he was the leading partner of the firm of Sadler, Fenton, and Company, of Belfast.

SADLER, *Sir Ralph*, an eminent English statesman, was born of a good family at Hackney in Middlesex in 1507. His shrewdness and address in business early began to lead him to promotion. While a mere child he was serving the secretary Cromwell with great acceptance. In his eleventh year he attracted the notice of the king, Henry VIII., and a series of appointments was the result. He was made clerk of the hamper, one of the gentlemen of the privy chamber, and a knight. His services were employed in dissolving the religious houses, and rewarded with a large share of the rich spoils. Above all, several successive embassies to Scotland were entrusted to his management. In 1537 he was sent thither to strengthen the English interest; in 1539–40 he was commissioned to persuade the Scottish king, James V., to cast off the supremacy of the Pope; in 1541 he went back to enforce this same counsel; and in 1542 he was appointed to settle the proposed match between Edward, Prince of Wales, and Mary the infant queen of Scots. Nor did Sadler's want of success on all these various occasions affect his prospects. Fortune still remained constant to him. On Henry's death in 1547, his name was found in the royal will as one of the councillors to the sixteen nobles who

were entrusted with the guardianship of the young king. In the same year he was appointed treasurer to the army sent against Scotland, and for his great services in rallying the repulsed cavalry he was dubbed a knight-banneret on the battle-field of Pinkie. Even the relentless vengeance of "bloody Mary" did not injure his prosperity. During her reign he lived in peaceful seclusion on his estate near Hackney. On the accession of Elizabeth in 1558, Sir Ralph Sadler came once more into a sphere of active employment. He immediately became a member of Parliament for the county of Hertford, and a privy councillor. Not long afterwards his intimacy with the affairs of Scotland recommended him as a fit person to take up his abode in the town of Berwick, and to support with secret supplies of money the Scottish lords of the Congregation in their resistance to their Popish queen-dowager. A number of years were spent in less obtrusive business; and he was then, in 1584, appointed keeper of Mary, Queen of Scots, in the Castle of Tutbury, an office which he discharged with great honesty and humanity. His last service was to repair to Scotland to pacify the king's indignation on account of Mary's death. He returned worn out with the labours of a long life, and died at his lordship of Standon in Hertfordshire in 1587. Sadler's *State Papers and Letters* were published in 2 vols. 4to, Edinburgh, 1809. Prefaced to that edition was a memoir by Sir Walter Scott, which has also appeared among that great author's prose works.

SADOLETO, JACOPO, a learned cardinal, was born at Modena in 1477. Leo X. made him and Peter Bembo his secretaries, an office for which they were both well qualified; and Sadoletto was soon afterwards made bishop of Carpentras, near Avignon. He was made a cardinal in 1536 by Paul III.; was employed in several negotiations and embassies; and died in 1547, not without the suspicion of poison, for corresponding too familiarly with the Protestants, and testifying too much regard for some of their doctors. His works, which are all in Latin, were collected in 1607 at Mentz, in one volume 8vo. They consist of a commentary on the Epistle of Paul to the Romans, a work on Education, a disputation in two books, on the merits of philosophy, and a poem on the discovery of the group of the "Laocoon" at Rome. His sincere piety and love of letters have led him to be compared with Fénelon.

SAFFI, or ASAFFI, a town of Morocco, in a barren valley between two hills, on the shore of the Atlantic, not far from Cape Cantiro. It was formerly a place of much European trade; and until 1641 belonged to the Portuguese, but now it is gradually decreasing in size and importance. The roadstead in front of the town affords good anchorage. Pop. about 9000, of whom 3000 are Jews.

SAFFRON, the dried stigmata of the common crocus (*Crocus sativus*), much used as a colouring ingredient both in food and medicine. Though affording a brilliant yellow colour, it can hardly be called a dye-stuff. This substance was formerly largely cultivated in England in the neighbourhood of Saffron-Walden. It is now chiefly imported from Spain, France, and the south of Europe, and is used in pharmacy. The total importations for 1857 from those parts were 12,175 lb., which, at L.1, 8s. 6d. per lb., cost L.17,349.

SAFFRON-WALDEN, a market-town and municipal borough of England, county of Essex, 22 miles N.N.W. of Chelmsford, and 42 N.N.E. of London. It stands partly in a valley at the foot, and partly on the sides and top of a hill that was formerly rich in saffron, so as to give the name to the town. Above all the other buildings the parish church is conspicuous, from its lofty situation. It is a fine Gothic pile, with an embattled tower. The streets are irregularly laid out, but many of them good; the houses have an antique, but generally neat appearance. There is a large market-place, in which stands an elegant town-hall

Sadoletto
||
Saffron-
Walden.

Sagan
Sage, Le.

The post-office and corn exchange are also handsome buildings, the latter in the Italian style. Besides the parish church, there are places of worship for Baptists, Independents, Quakers, Wesleyan and Primitive Methodists. For public instruction the town has a free grammar school, founded in 1522; national, British, and infant schools; a museum, and a literary institution. Here stands part of the walls and towers of an ancient castle built by Magnaville, a Norman knight who came over with the Conqueror. The only manufactories of importance are an iron foundry and a brewery. Bailey and malt are the chief articles of trade. Markets are held weekly, and there are three annual fairs. The borough is governed by a mayor, three other aldermen, and twelve councillors. Near Saffron-Walden is Audley End, the seat of Lord Braybrooke, built on the site of an old monastery. Pop. of the borough (1851) 5911.

SAGAN, a town of Prussia, province of Silesia, on the Bober, in the government and 48 miles N.W. of Liegnitz. It is strongly fortified, and entered by three gates. There is a large and handsome ducal palace, with fine parks, gardens, and hot-houses. There are one Protestant and five Roman Catholic churches here, also a Roman Catholic school. Woollen and linen cloth is manufactured; and there is an important trade in corn. The principality of Sagan, with an area of 420 square miles, and a population of 52,000, was sold in 1628 by the Emperor Ferdinand II. to Wallenstein; after whose death it passed to the princes of Lobkowitz, who sold it in 1785 to Duke Peter of Courland. This duke abdicated his sovereignty in 1795, retaining his titles and honours; and his second daughter was created duchess of Sagan in 1845. Pop. of the town, 8948.

SAGE, ALAIN RENÉ LE, author of *Gil Blas*, and the greatest of the French novelists, was born at Sarzeau, near the town of Vannes in Brittany, on the 8th of May 1668. His father, Claude Le Sage, a lawyer, who held the office of registrar of the Cour Royale of Ruis, having died while his son was yet young, left him a small property, and entrusted him to the care of a worthless uncle, who sent him to the Jesuit's college of Vannes, but who seems otherwise to have neglected both the fortune and education of the future novelist. Père Bochart, principal of his college, early detected the lurking genius of the young scholar, and took great pleasure in cultivating his growing taste for letters. On leaving this institution, he was compelled to accept of an office in connection with the collection of taxes of Brittany, which he held for five or six years. Leaving this situation, he went to Paris in 1692, and entered the university with the intention of prosecuting the study of philosophy. His youth, talents, and taste, combined with a remarkably handsome person, soon gained ready access for Le Sage to the best society of the French capital. In 1604 he married a beautiful girl, the daughter of a joiner in Paris, and with this date begins the activity of a long and a very happy life. He was induced by Danchet, professor of rhetoric at Chartres, whom he had known at the university of Paris, to translate into French the *Letters of Aristænetus*. This volume appeared at Chartres in 1695, at the expense of the professor, but with the imprint of Rotterdam. Le Sage continued to frequent the literary circles of Paris, and had the good fortune to make the friendship of the Abbé de Lyonne, who, besides bestowing upon him a pension of 600 livres, deserves the gratitude of posterity, for introducing him to the literature of Spain, which he was afterwards to combine in such a striking manner with that of his own country. Then followed each other in quick succession the comedy of *Le Traître Puni* in 1700, translated, or rather imitated from the Spanish of De Roxas; *Don Felix de Mendocce* in 1700, from a piece by Lope de Vega; *Le Point d'Honneur*, a comedy also taken from De Roxas; and *Les Nouvelles*

Aventures de Don Quichotte, from the Spanish of Avelaneda. In none of these works, however, did the translator meet with any success. Le Sage had now reached his thirty-eighth year, and a superficial observer would have pronounced his life a failure. Genius, however, of the permanent kind, is usually of slow growth; and while Le Sage had been wasting, according to some, the brightest years of his life in idle folly, he was nevertheless receiving a discipline in making his own the wonderful wealth of the Spanish drama, which should ultimately open up for him a more brilliant triumph than any which the French nation then knew. Hitherto he had confined himself to translations or imitations. He was now to enter more boldly upon his voyage to literary fame, by committing himself more freely to the element than hitherto had been the case. In 1707 his comedy of *Don César Ursin* appeared at the Théâtre Français, with no success; but a small piece of his own, entitled *Crispin, Rival de son Maître*, had a brilliant run, and is said to be almost equal to Molière in the truthfulness of its dialogue. The success of his next work, the *Diable Boiteux*, 1707, was enormous. Its title and plan were derived from *El Diablo-Cojuelo* of Guevara, but the fancy, the gaiety, the wit, and the vivacity of it, were entirely the work of his charming French pen. Its pictures and characters, many of whom were sketched from real Parisian life, were purely French, and yet truly world-wide; and its nervous, clear, and uncommonly accurate style, gained for it a lasting reputation. (See "Le Sage" in the article ROMANCE.) He increased this work by an additional volume in 1726, and in 1737 added to it the *Entretien des Cheminées de Madrid*. In 1708 he brought forth a regular comedy in five acts called *Turcaret*, in which he satirized with unsparing hand those financiers and men of business, who, inflated by their sudden rise in the world, so frequently outrage all propriety, and even decency, by the absurdity of their conduct and the rudeness of their manners. A cabal of those concerned in the finances clubbed together to put it down, but an order from Monseigneur, dated 15th October 1708, "commanded" the king's company to play it forthwith. It was accordingly performed on the 14th of February 1709, and had a much greater success than could have been expected. An anecdote of this period illustrates well the character of Le Sage. Chancing one day to be some hours late for a meeting which had been arranged at the Hotel de Bouillon, at which he was to read his manuscript comedy, when he appeared he pled an engagement as an excuse, upon which the Duchess of Bouillon haughtily remarked that he had made the company lose two hours. "It is easy to make up the loss, madam," replied Le Sage; "I will not read my comedy, and you will thus regain the lost time." He stepped out of the hotel, and never after could he be prevailed on to return. Shortly after, he broke off all connection with the Théâtre Français. He offered them a small piece in 1708, called *La Fontaine*, but it was not performed till 1732. This, combined with other indignities, created in Le Sage that bitter dislike towards performers which all readers of his romance will remember. He never permits an opportunity to slip without holding them up to indignant scorn.

With the exception of the comic opera *De la Foire*, for which he composed, either in whole or in part, upwards of a hundred small pieces, calculated to beguile the tedium of the hour, he bade adieu to the theatres, and began to compose those delightful romances for which posterity have never ceased to bless the name of Le Sage. His great work, *Gil Blas de Santillane*, which was published in the following order—2 vols. in 1710, 1 vol. in 1724, and 1 vol. in 1735, raised his fame to the very highest pitch, and secured it upon an immovable basis. "Few," says Sir Walter Scott, in his biographical notice of Le Sage, "have ever read this charming book without remembering,

Sage, Le.

Sage, Le.

as one of the most delightful occupations of their life, the time which they first employed in the perusal; and there are few also who do not occasionally turn back to its pages with all the vivacity which attends the recollection of early love." (See ROMANCE.)

Three distinct charges have been made against this work. The first was brought by Bruzen de la Martinière, and followed up by Voltaire in his *Siècle de Louis XIV.* in 1752, who unite in pronouncing the *Gil Blas* "to be entirely taken from Espinel's *Marcos de Obregon*," an accusation as absurd as it was malignant. The secret of Voltaire's dislike to the book was his having been subjected to a personal caricature in it. The next attack on the authenticity of *Gil Blas* was made by the Jesuit Father Isla, who published a Spanish translation of it, claiming it as "stolen from the Spanish, and now restored to its own country and native language by a Spaniard who does not choose to have his nation trifled with." Isla declares, without the shadow of proof, that it was originally the performance of an Andalusian advocate, who had given his manuscript to Le Sage when on a visit to Spain, as French secretary to some ambassador. This was of course as great a fiction as the first charge; for neither manuscript nor advocate were ever forthcoming, and Le Sage was never in Spain. These two charges have both been refuted by Le Comte François de Neufchâteau, in his *Examen de la Question de savoir si Le Sage est Auteur de Gil Blas*, 1819. A third, and in some respects a more ingenious, attack was made upon the reputation of Le Sage by Llorente, in two works, the one in French, the other in Spanish, 1822, who asserts that *Gil Blas* was the work of Solis, for this very good reason, that no one was capable, in the judgment of Llorente, of writing such a romance except the eminent historian. Ticknor, who in his *Spanish Literature* devotes some pages to an examination of these charges, remarks,—“There is a ready answer to all such merely conjectural criticism. Le Sage proceeded, as an author in romantic fiction, just as he had done when he wrote for the public theatre; and the results at which he arrived in both cases are remarkably similar; . . . the *Gil Blas*, the greatest of all his works of prose fiction, is the result of his confirmed strength, and in its characteristic merits is as much his own as the *Turcaret*. On this point the internal evidence is as decisive as the external.”

Le Sage meanwhile pursued his honest labour, and reaped the fruits of his industry by securing an independence. His *Roland l'Amoureux*, 1717, was a rather poor imitation of Bojardo's *Orlando Innamorato*; but his *Guzman d'Alfarache*, which appeared in 1732, was a great improvement upon the original Spanish work of Aleman. In the same year he published the *Les Aventures de Robert dit le Chevalier de Beauchesne*, 2 vols., a sort of Paul Jones who scoured the West Indian seas during that period. This work was followed in 1733 by *L'Histoire d'Estevanille Gonzales surnommé le Garçon de bonne Humeur*, 2 vols., avowedly imitated from *El Escudero Obregon*, but to which it bears a very distant resemblance. Next year he published *Une Journée des Parques*, a philosophical piece, written with great wit and boldness. In 1738 appeared the *Bachelier de Salamanca*; and in 1740 *La Valse Trouvée*, which appeared anonymously. His last work, *The Melange Amusant de Saillies d'Esprit et de Traits Historiques les plus frappants*, a lively collection of anecdotes and criticisms, was published in 1743. The long domestic tranquillity and happiness which Le Sage had enjoyed, and which was only interrupted by his eldest and youngest son becoming actors, was now wearing gradually to a close. His eldest son, who had been bred to the bar, and who, on assuming the sock, took the name of Montménil, gained a high reputation as an actor. This very amiable man died suddenly in 1743, shortly after he

had been reconciled to his father. His second son became canon of the cathedral of Boulogne, and on his father's ceasing to ply his pen, had the gratification of affording him a shelter in his retirement. Le Sage died at his son's residence on the 17th November 1747, in his seventy-ninth year.

Most of Le Sage's works of any importance were published under the title of *Œuvres Choieses de Le Sage*, 15 vols. 8vo, Paris, 1783, and 16 vols. 8vo, Paris, 1810. The *Diabre Boiteux* has been translated into English under the title of *The Devil on Two Sticks*; the *Vamille Gonzales*, and most of his other novels of much importance, have likewise been translated into English. The *Gil Blas*, which has appeared in all the languages of Europe, has been translated into English by Dr Smollett.

SAGHALIEN, TARAKAI, or KRAFTO, an island of Asia, lying off the coast of Mantchooria, between N. Lat. 46. and 54. 20. It extends nearly due north and south for a distance of 600 miles; its greatest breadth at the head of the Bay of Patience is about 120 miles, its average breadth 50, and its area more than 30,000 square miles. The sea of Ochotsk washes it on the east, on the west the sea of Tartary separates it from Mantchooria, and on the south the Strait of La Pérouse divides it from the island of Jesso. The coasts are much indented, but there are few harbours or safe anchorages. The southern portion of the island is occupied by a chain of mountains stretching northwards from Capes Crillon and Aniva, which form the twofold extremity of the island, to about the middle. Few of the summits exceed the height of 5000 feet, but they are covered with snow for a great part of the year. Between the mountains and the sea there is in general a narrow strip of land densely covered with lofty trees. About the centre of the island is a low, swampy, and sandy flat; while the extreme north is occupied with a hilly and fertile country. The coast here consists of lofty white cliffs. The climate is generally cold, and dense fogs almost always enshroud the island. Oak, fir, birch, and maple compose the forests, and afford excellent timber; gooseberries, raspberries, and strawberries are the principal fruits. Bears and martens are the wild animals most numerous; salmon and herring are caught, cured, and exported. Whales are obtained in large numbers along the east coast and in the Strait of La Pérouse. The natives call themselves *Amos*, or men, and they resemble the people of the Kurile Islands. They make a kind of cloth from willow-bark, and build large and strong boats. A few Japanese and Mantchoos have settled on different parts of the island. The whole of the island now belongs to the Russian empire, the southern portion having been obtained within recent years from Japan, to which empire it had previously belonged.

SAGITTA. See ASTRONOMY.

SAGO, a species of starch obtained from several palms, of which the most common are *Sagus Rumphii*, *S. Caevis*, and *Saguerus Rumphii*. It forms when cooked a bland, mucilaginous, and nutritive substance, and is commonly given to children and invalids. The sago is obtained from the pith of the palm, and is shaped into grains by being passed through a coarse sieve when half dry. This process of granulation is unknown to Europeans. Sago was imported from the British East Indies, Sumatra, Borneo, and other parts, to the amount of 149,416 cwt. in 1857; the cost of which, at L.1. 2s. 4d. per cwt., was L.166,848. It pays 4½d. per cwt. of duty.

SAGUM. See PALUDAMENTUM.

SAGUNTUM, an ancient town of Spain, in the country of the Edetani or Sedetani, in the Roman province of Hispania Tarraconensis. It stood on a hill near the shore of the Mediterranean, about 100 miles S.W. of the mouth of the Ebro. It is said to have been founded by Greeks from Zacynthus, along with Rutuli from Ardea; and the fertility

Saghalien
||
Saguntum.

Sahara
||
Sail.

of the surrounding country, together with the commercial activity of its inhabitants, raised the town to a high position. The figs of the vicinity were highly esteemed; and the name of Saguntum was widely known for the earthenware cups manufactured there. At a time when the greater part of Spain was under Carthaginian influence Saguntum was an ally of Rome; but it was besieged by Hannibal in 219 B.C. This act of aggression, as it was considered by the Romans, formed the pretext for the second Punic war. After a desperate resistance, Saguntum was taken by Hannibal, but recovered in 210 by the Romans. After this period it became a Roman colony. The site is now occupied by Murviedro, which derives its name, a corruption of *muri veteres*, from the ancient fortifications in the place. (See MURVIEDRO.)

SAHARA. See AFRICA.

SAIDA, or SAID, a town of Syria, occupying the site of the ancient *Sidon*, on the Mediterranean, about 20 miles S. of Beyrout. It stands partly on level ground, and partly on a slope; the streets are narrow, gloomy, and dirty. Mosques and bazaars are the principal buildings. Here is a harbour and an old castle. Silk is manufactured in the town. Pop. 8000. (See SIDON.)

SAIGON, SAIGONG, or SAIGUN, a town of Anam, in the province of Cambodia, on a small affluent of the River Saigon or Mekong, about 30 miles from the sea. It may be considered the capital of the province, as it is the seat of the government. It consists of an old and a new town; the latter, called Pingeh, is on the main river, about 3 miles from the other. Here is the residence of the governor, and a citadel built in the European style by French engineers; also arsenals and ship-building docks. Both this and the old town are intersected with numerous canals, on which boats are continually plying; and many people here, as in some parts of China, live wholly on the water. The streets are straight and handsome, lined with shops built of bamboo; the houses of the Chinese are the largest and best in the place. At the beginning of this century the trade of the town was very considerable, but now hardly ever does a foreign vessel enter the river. China-ware, silk, paper, tea, &c., are sold in the shops, as well as a few European goods. Pop. about 30,000.

SAIL, in navigation, an assemblage of several breadths of canvas, sewed together by the lists, and edged round with cord, fastened to the yards of a ship, to make it drive before the wind. The edges of the cloths or pieces of which a sail is composed are generally sewed together with a double seam; and the whole is skirted round at the edges with a cord called the bolt-rope. Although the form of sails is extremely different, they are all nevertheless triangular or quadrilateral figures; or, in other words, their surfaces are contained either between three or four sides. The former of these are sometimes spread by a yard, as lateen-sails, and otherwise by a stay, as stay-sails, or by a mast, as shoulder-of-mutton sails; in all which cases the foremost leech or edge is attached to the said yard, mast, or stay, throughout its whole length. The latter, or those which are four-sided, are either extended by yards, as the principal yards of a ship; or by yards and booms, as the studding-sails, drivers, ring-tails, and all those sails which are set occasionally; or by gaffs and booms, as the main-sails of sloops and brigantines. (See SHIP, and SHIP-BUILDING.) Sail is also a name applied to any vessel seen at a distance under sail, and is equivalent to ship. To *set* sail, is to unfurl and expand the sails upon their respective yards and stays, in order to begin the action of sailing. To *make* sail, is to spread an additional quantity of sail, so as to increase the ship's velocity. To *shorten* sail is to reduce or take in part of the sails, with an intention to diminish the ship's velocity. To *strike* sail is to lower it suddenly. This is particularly used in saluting or doing homage to a

superior force, or to one whom the law of nations acknowledges as superior in certain regions. Thus all foreign vessels strike to a British man-of-war in the British seas.

SAILING. See NAVIGATION.

SAINT. See CANONIZATION.

SAINT-ARNAUD, MARSHAL LEROY DE, a brave French general, was born of poor parents at Paris in 1801. His fiery disposition made him an ardent soldier. He entered the *Gardes du Corps* at the age of ten. It is true that he soon afterwards became stage-struck, and played for several years in the suburban theatre of the Batignolles; but the revolutionary turmoil of 1830 once more roused his passion for military renown. Being engaged in the war of La Vendée, he fought his way rapidly towards promotion. He continued to rise after he went to Algiers in 1836. His valour at the siege of Constantine gained for him the decoration of the Legion of Honour. In every successive battle his sword achieved for him a higher position than he had held before. He was especially successful in 1851 in his expedition against the Kabyles. With little more than 6000 men he overran the whole of that savage district, and achieved one of the greatest campaigns ever carried out by his countrymen in Algeria. At length, on his return to France, he was taken into the confidence of Louis Napoleon, and made minister of war in 1851, and a marshal in 1852. He had hitherto appeared perhaps too much in the light of a reckless and not very scrupulous adventurer; but on the outbreak of the Crimean war the valour of Saint-Arnaud shone forth in a much clearer light. It had long been the desire of his heart to command the French eagles on a European field, and he was now eager to gratify it. The mark of death was already upon him, but he set out to the seat of war. His disease was stealthily making way when he landed at the Crimea; but he kept down every symptom of pain, and manned himself to lead his troops against the enemy. Accordingly, on the 20th of September, the day of the Alma, he mounted his horse with great difficulty, and amid the turmoil of battle showed all his former fire, energy, and decision. Even after the victory was gained his enthusiasm still continued to burn, and he wrote home despatches remarkable for the high tone in which he recounted the bravery of the English and French armies. It was not until the 27th that the disease mastered him, and forced him to resign his command. The end of Saint-Arnaud was now fast approaching. On the 29th of September he died at sea off the Crimea; and on the 19th of October he was deposited in the vaults of the Invalides with every mark of honour. The *Letters* of Marshal Saint-Arnaud have been published by his brother in 2 vols. 8vo, Paris, 1855.

SAINT-SIMON, CLAUDE HENRI, *Comte de*, founder of the sect which bears his name, was born of a family which claimed kindred with the old counts of Vermandois and the Emperor Charlemagne, on the 17th October 1760. His grandfather was the famous Duc de Saint-Simon, author of the *Memoirs*; but his father having lost his ducal designation, Claude Henri, although counting kindred with emperors, had to commence life among the lower grades of the French noblesse. Having received a solid education under the teaching of such men as D'Alembert, this youth, remarkable from the first for restless eccentricity, entered the American service as a French officer in 1777. Here he fought under Bouillé and Washington, and was made prisoner in 1782 with De Grasse. Returning to Paris in the following year he was made colonel of a regiment of Aquitaine. From his earliest recollection he had dreams of his future greatness, and his servant had been long instructed to awaken him with "Levez-vous, M. le Comte, vous avez de grandes choses à faire." After various unsettled wanderings in France and Spain, he at last came to the conclusion that something must be done for "the advancement of

Sailing
||
Saint-Simon.

Saint-Simon.

human civilization." He had reached nearly his fortieth year when he resolved to commence a thorough course of study preparatory to the inauguration of the new scheme which was troubling his brain. All he knew as yet was that it must be a "physico-political" reformation which he was to effect. He accordingly commenced a ten years' course of intellectual and practical study, to put himself thoroughly abreast of the knowledge of the world. Taking up his residence near the Ecole Polytechnique, and subsequently near the Ecole de Médecine, he began his "theoretical education." Here he studied the physical sciences, and acquainted himself with the whole field of physiological knowledge. This department completed, he entered upon his "experimental education." He now strove to realize "in his own person the whole range of human situations and emotions," to enable him the more fully to fraternize with humanity in every phase. He married, he gave dinners, he got up balls. He played, he drank, he debauched himself. Old age was artificially brought near; rosy youth was counterfeited by medicaments; contagious diseases were courted; and, in short, all the appliances of science and art were laid under contribution to the gratification of pleasure or the production of pain. All moral law was set at defiance, but Saint-Simon calmly took refuge in the plea, that the end justifies the means. Could not a man be permitted any amount of self-indulgence when he kept his eye steadily on the highest theoretical philosophy? For a man to seek self-indulgence through sheer love of pleasure, was one thing; for a man to court self-indulgence through pure love of experimental philosophy, was quite a different thing. The one was simply another name for perdition; the other was the high road to virtue. So reasoned Saint-Simon. He rose from the giddy whirl under which all this process of experimentalism had submerged him, just in time to discover that his money was all spent. He was now glad to accept a clerkship at L.40 a year. Poverty stared him in the face; but the genius of his great mission beckoned him on. In 1812, when he had reached at once the brink of starvation and of fifty-two, he gave to the world his first publication. It bore the name of *Letters from an Inhabitant of Geneva to his Contemporaries*. In this work we discover the germs of his social philosophy, which, to say the least, were sufficiently shadowy. All men of thought were to form the spiritual order, all men of action the temporal order,—an adaptation to modern society of the mediæval distinction of the Romish Church. These *Letters* were followed up by an *Introduction to the Scientific Labours of the Nineteenth Century*. Startled by the novelty, and excited by the original views of these works, a few ardent youths began to gather round Saint-Simon, over whom the master exercised the fascination of an enthusiast. There were Olinde Rodrigues, Augustin Thierry, and Auguste Comte the well-known author of the *Philosophie Positive*. The Saint-Simonian school being thus inaugurated, the pupils began their tasks under the eye of their master. *The Re-organization of European Society* appeared in 1814, by Saint-Simon and Thierry; and in 1819 a small pamphlet called the *Parabole*, by the same authors. The doctrines promulgated in this brochure were subsequently elaborated in more formal works, particularly in the *Catechisme des Industriels*. Next appeared the *Système de Politique Positive* of Auguste Comte, afterwards developed into the *Cours de Philosophie Positive* of the same author. In that work Comte neglected too much the sentimental and religious elements for the taste of his master. Saint-Simon's work of reform succeeded very slowly; poverty still haunted him in his obscurity; the great master became tired of life, and attempted suddenly to blow out his brains. He had miscalculated upon his courage, for he only succeeded in getting rid of an eye. This occurred on the 9th of March 1823. Whether he continued to instruct his servant as

to what he should call to his master each morning does not appear. He was probably content when the menial had announced the simple "Levez-vous." He was evidently much confused as to his own destiny; and indeed the gradual approach of that life-long hallucination of which Saint-Simon had been the dupe, now became more and more apparent. Paris continued scantily to supply his school with new pupils; and Bazard and Enfantin now sought the person of this industrious teacher. Whether or not the ideas of Saint-Simon had gained clearness and solidity by the recent opportunities which he had of gazing into the world of spirits, he at all events now announced it as his intention to leave his last bequest to the world in the form of a new religion. The *Nouveau Christianisme*, in 1825, contained an exposition of his great religious maxim, "Love one another." Everything both in substance and form connected with Christianity was destined to a progressive change; only this adage was to remain eternal and immutable. First came Catholicism; next came Protestantism; and lastly, men were to enjoy the mild sway of Saint-Simonianism. This revolution was to be effected by two principles—an end and a means; first, "The most rapid possible amelioration, physical and moral, of the condition of the class the most numerous and poor;" and the means of effecting this was, "To each man a vocation according to his capacity, and to each capacity a recompense according to its works." The last act of Saint-Simon's life was the organization of *Le Producteur*. This journal, afterwards to be conducted by Rodrigues, Bazard, and Enfantin, was to be the vehicle on which pure Saint-Simonianism was to be wheeled to the doors of the citizens of Paris. The master now, after much experience of ill-health, was to bestow his last instructions upon his pupils. They gathered round the couch of the dying man, when he addressed them as follows:—"It has been imagined," said he, "that all religion must disappear. But religion cannot disappear from the world; it can only change its form. Do not forget this; and remember that, in order to do great things, one must be enthusiastic." Simple words, and yet possessed of more truth than the speaker was aware of. He died on the 19th of May 1825, aged sixty-five years.

The subsequent history of Saint-Simonianism is curious. On the death of the master, M. Bazard announced himself as his successor, and began to lecture on his creed. Fresh pupils flowed in, and in a short time they formed themselves into a little church, which chose as its creed a mystical theosophy composed mainly of the more reconcilable doctrines of their deceased master. They dwelt together in the Rue Morsigny, and started a weekly journal called the *L'Organisateur*. On the establishment of the government of Louis Philippe, the sect made considerable progress. They gained an able coadjutor in Pierre Leroux, editor of *Le Globe* newspaper, by the conversion of whom they gained over the influence of this important journal as a vehicle for disseminating Saint-Simonianism. The result was an immense increase in their numbers throughout all parts of France, particularly among the young and well-educated. A schism soon occurred, however, among their leaders as to some peculiar points of doctrine, of which the most important was "the future of women." Enfantin wishing to proclaim the social equality of the sexes, the rest of the fraternity formally seceded. A government prosecution led to the dissolution of the Society of the Rue Morsigny, and *Le Globe* newspaper became defunct. Enfantin could not brook the idea of allowing Saint-Simonianism to die so cheaply; and he accordingly, with some forty adherents, retired to a country house in the neighbourhood of Paris, and instituted a sort of monastery, in which the duties of the devotees were divided between manual and intellectual labour. This institution was broken up, and Saint-Simonianism dispersed, by a public prosecution on the

Saint-Simon.

Saint-Simon.

27th of August 1832. Since that time the creed has become virtually extinct; but the Saint-Simonian notions still operate in French thought, and it is really astonishing to observe how strong a hold the system must have taken upon the minds of thinking men, when we find in so many public departments of the French state, the outgrowths of the industrialism taught by the descendant of the Vermandois.

SAINT-SIMON, *Louis de Rouvroy, Duc de*, author of the celebrated *Memoirs of the Court of France under Louis XIV. and his Successors*, was born at Paris, of a family claiming kin with the old counts of Vermandois and the Emperor Charlemagne, in 1675. From his earliest years he was accustomed to the presence of royalty, having been presented at the font by Louis XIV. and by Maria Theresa of Austria. He embraced early the military profession, and served under the Marechal de Luxembourg in 1692, when he signalized himself by his valour at the siege of Namur and at the battles of Fleurus and of Nerwinden. The following year he rose to be captain and colonel; but was arrested in his military progress by the death of his father in 1693, who left him heir to his titles and his estate. Louis de Rouvroy, now Duc de Saint-Simon, exchanged the military attire for the dress of the diplomatist. In this new sphere he would have risen to distinction by the brilliancy of his talents, had not the native independence of his character interfered. The king, it is said, overlooked him; the royal councils were filled by meaner men; and the Duc de Saint-Simon occupied his time in secretly transferring to paper the characters of the court. This staunch aristocrat was a firm Jansenist, and looked with no favourable eye on the rise of Madame de Maintenon. He opposed the scheming Jesuits; he warned the populace against the financial projects of Law; he strongly advocated the claims of the Duc d'Orleans to the regency, and used all his efforts to counteract Cardinal Dubois. Such measures were calculated to elevate his name among the populace; but he was a French peer, and opposed to every plan of reform. Though supporting the regent, he was too independent a man to follow him servilely. In 1721 he performed a fruitless embassy to the court of Spain in support of the marriage of the Infanta with Louis XV., who was then a minor. On the death of Orleans and the ascension of Louis, this proud old aristocrat retired in disgust from the court, and occupied his remaining years in writing his *Memoirs*. He died at Paris on the 2d of March 1755.

These famous *Memoirs*, now known over the whole world, consist of a curious compound of history and of biography, written in a somewhat rough style, but with great honesty of purpose, and with an exceedingly clear eye for truth. His vivid perception of character, his stores of illustrative anecdote, and his boundless detail of quaint and curious allusion, despite the strong prejudice of the author, constitute his book the most invaluable record of the life and manners of the age of Louis XIV. and of the regency. The family of the author obtained after his decease a *lettre de cachet* for the deposition of the original manuscript in the national archives, not judging it prudent to publish it while the characters it described were alive. After many ineffectual attempts to recover the MS., the Abbé Voisenon was commissioned by Louis XVI. to examine it. The work was retained; but the Abbé made large extracts and copies from it, which were afterwards surreptitiously got hold of, and printed in 7 vols. in 1788 and 1789. In 1791 Soultavie issued another edition, but still incomplete, in 13 vols. 8vo. In 1829-30, by order of Louis XVIII., the first complete edition was given to the world in 21 vols. 8vo. Another edition, in 20 vols. of superb typography, by M. de Chéruel, with an introductory notice by Sainte-Beuve of the French Academy, was published in 1856-57. Since then there have been numerous editions of this highly interest-

ing book. An English translation of select portions of St Andrews the *Memoirs*, by Bayle St John, was published in 4 vols. in 1857.

ST ANDREWS. See ANDREWS, ST.

ST ANTONIO, one of the Cape de Verd Islands. (See VERD, CAPE.)

ST CATHARINES, a town of West Canada, in the county of Lincoln, on a beautiful table-land above the valley traversed by the Welland Canal, 11 miles W. of Niagara, the county town. The surrounding country is so fertile as to have acquired the name of the Garden of West Canada, and the town is much resorted to during the summer. There are many elegantly fitted-up hotels here. Machinery and farming implements are extensively manufactured. Pop. about 6500.

ST GEORGE, one of the Azores. See AZORES.

ST HYACINTH, a town of East Canada, in the county of the same name, on the River Yamaska, 30 miles E. by N. of Montreal, and 137 S.W. of Montreal. The Roman Catholic college, founded in 1812, occupies a fine stone building surmounted by a dome, and has beautiful grounds. The number of professors and directors is 23, that of students 343; and there is an excellent library of 7000 volumes. There are also in the town an episcopal palace, court-house, city-hall, and market. Public education and the relief of the destitute sick are provided for by schools and hospitals. Numerous manufactures are carried on, and the place is one of the most thriving commercial towns of Canada. Pop. about 5000.

ST IAGO, one of the Cape de Verd Islands. See VERD, CAPE.

ST JOHN'S, *New Brunswick*. See NEW BRUNSWICK.

ST JOHN'S, *Newfoundland*. See NEWFOUNDLAND.

ST MICHAEL'S, one of the Azores. See AZORES.

ST NICHOLAS, one of the Cape de Verd Islands. See VERD, CAPE.

SAINTES, a town of France, capital of an arrondissement in the department of Charente-Inférieure, on a hill on the left bank of the Charente, here crossed by a stone bridge, 43 miles S.E. of Rochelle. From whatever side it is viewed the town presents a very picturesque appearance. From the south it is approached through a fine avenue of trees; but in the interior it consists of irregularly-arranged, ill-built houses. The cathedral occupies the site of a church built by Charlemagne, and has an ancient portal and tower. Another fine old edifice is the church of St Eutrope, which dates from the eleventh century. It is remarkable for a large and curious crypt. Two remains of the period of the Romans are still to be seen here: the amphitheatre, equal in size, but much inferior in beauty, to that of Nîmes; and a triumphal arch of limestone, but of no great beauty, on the bridge. The latter bears inscriptions, recording it to have been built in honour of Germanicus, his father Drusus, and his uncle the Emperor Tiberius. Saintes is the seat of courts of law, a theatre, public library, college, museum, &c. Woollen fabrics, hosiery, leather, earthenware, &c., are manufactured here; and some trade is carried on in cognac brandy from the adjacent districts, as well as in corn and wool. Pop. (1856) 10,664.

SAINTONGE, an old province of France, of which Saintes was the capital, bounded on the N. and N.E. by Poitou, E. by Angoumois; S. by Guenne, and W. by Aunis. It now forms a small portion of the department of Charente, and the greater part of that of Charente-Inférieure.

SAIS, an ancient city of Lower Egypt, capital of a district in the delta, on the right bank of the Canopic or Rosetta arm of the Nile, in N. Lat. 31. 4. It was built on artificial mounds, so as to be out of the reach of the inundations of the Nile, and covered an extensive area, as it was a place of great importance in ancient times. It was

||
Sais.

Saladin
||
Salamanca.

especially famous as a sacred city, devoted to the worship of Neith or Athene, and of Isis. The temple of the former deity appears to have stood in a large inclosure surrounded by massive walls of brick. It had a portico erected by Amasis, which was one of the most splendid in Egypt. To the same monarch this temple owed several colossal statues and sphynxes, as well as a large shrine made out of a single block of granite. Sais also contained the tombs of all the Saite kings of Egypt; that is, the single monarch of the 24th, the six of the 26th, and the single one of the 28th dynasty. The reigns of these monarchs form one of the most flourishing periods of Egyptian history, during which Sais reached the acme of its prosperity. The place was equally celebrated as a seat of learning and commerce, and had many institutions that resembled those of Athens. The remains of Sais consist of mounds of brick mingled with fragments of marble and granite. Except that of the temple of Neith, no site of any of the edifices in the town has been discovered. There are some traces of the lake where the annual mysteries of Isis were celebrated. (See EGYPT.)

SALADIN, or more properly **SALAH-ED-DEEN**, a celebrated sultan of Egypt, who flourished between A.D. 1137 (A.H. 532) and A.D. 1192 (A.H. 589). (For further notice of him, see ARABIA.)

SALAHIEH, or **SALHIEH**, a town of Lower Egypt, near the Pelusiatic arm of the Nile, 37 miles N.E. of Belbeis. It is surrounded by palm trees, and contains a large mosque. Near this are the ruins of Tahpanhes, mentioned in Scripture as the seat of a palace of the Egyptian monarchs. Pop. 6000.

SALAMANCA, a province of Spain, bounded on the N. by those of Zamora and Valladolid, E. by that of Avila, S. by that of Caceres, and W. by Portugal; area, 8158 square miles. It is for the most part mountainous; but contains many fine plains and valleys, a large proportion of which, as well as the slopes of the mountains, is covered with forests of oaks and chestnuts. The River Tormes enters the province in the south-east, flows first north and then west into the Douro, which forms a portion of the N.W. boundary of the province. The west part of the country is watered by the Agueda, another affluent of the Douro, and the south by the Alagon, which rises here, and flows southwards to join the Tagus. The River Alagon has in some places auriferous sands. The other important minerals obtained here are iron, copper, lead, rock-crystal, and saltpetre. Corn of various kinds, wine, oil, honey, almonds, and other fruits, are among the productions of the country. From the neighbourhood of Ciudad Rodrigo a great quantity of madder is exported to Portugal. Besides Salamanca the capital, the chief towns in the province are Alba, Tormes, Barca, Salvatierra, and Ciudad Rodrigo. Many important historical events have taken place here, especially during the Peninsular war. Pop. (1857) 280,722.

SALAMANCA, the capital of the above province, on the Tormes, 45 miles N.E. of Ciudad Rodrigo, and 120 N.W. of Madrid. It is built on three hills, in the centre of a curve formed by the river, which flows beneath the walls and domes of the picturesque old town. Antique, venerable, and stately, but desolate and dreary, are its narrow, steep streets and palatial mansions. The glory of the place as a seat of learning and religion is a thing of the past; younger universities have robbed it of its pre-eminence, and the ravages of war have laid in ruins the greater part of its academic buildings. Still there are many noble architectural remains to recall the time when its stately piles obtained for Salamanca the title of the Little Rome (*Roma la Chica*). The Plaza Mayor is the largest square in Spain, and can hold on the occasion of a bull-fight from 16,000 to 20,000 spectators. It is surrounded by colonnades and public buildings. The university was founded about 1200 by Alfonso

Salamis.

IX. of Leon, and enlarged by union with that of Palencia in 1239. It soon rose to eminence; and its professors attained a European reputation before the revival of learning, from their acquaintance with the Arabian writers, and through them with the Greek. In the fourteenth century it numbered 14,000 students; but soon afterwards it became stationary, while the rest of Europe was rapidly advancing in science and literature; and it was subsequently celebrated only for medicine and theology. At the time of its greatest prosperity there were four *colegios mayores*; namely, San Bartolomé (1410), Cuenca (1506), Santiago (1521), and Del Rey, or King's College (1625); and twenty-one *colegios menores*. The former taught classics, law, medicine, and theology; the latter grammar and rhetoric. The greater colleges were aristocratic foundations, possessing extensive privileges and patronage; but these were very much reduced in 1770. Among the university buildings are the schools (*escuelas*) built in 1415, where degrees were conferred, synods held, and disputations conducted. It has a fine library and chapel, lecture-rooms, and spacious halls, now deserted. The university library has a magnificent front, most delicately carved in the fine cream-coloured stone so much used at Salamanca. It is one of the finest works of the age of Ferdinand and Isabella. Of the four greater colleges which alone now remain, San Bartolomé is much admired; but it is heavy and disfigured by modern additions; Cuenca was formerly the gem of the place, and the little of it that has survived the French invasion shows what it must have been; Santiago has an exceedingly graceful and ornamental quadrangle; and King's College is a simple Doric edifice. The other collegiate edifices were ruthlessly destroyed by the French to construct fortifications, which the British took in a few hours. The whole number of students at the university in 1845 was 302. Salamanca has two cathedrals, an old and a new: the former a massive strong edifice, much like a fortress, and commanding from its tower a fine view; the latter a beautiful specimen of Gothic of the age of Leo X., although some parts of it were not completed till as late as 1734. It has a nave and two aisles, and its principal dimensions are as follows:—Length, 378 feet; breadth, 181; height of the nave, 130 feet; of the aisles, 80. Besides these, Salamanca contains twenty-five other churches and thirty-three former convents, the greater part of which have been much injured by the French. There are few manufactures and no commerce in the town. On the adjacent plains was fought the battle of Salamanca, July 22, 1812, when Wellington defeated the French under Marmont. Pop. (1849) 15,000.

SALAMIS, or **KOLURI**, an island of Greece, in the Saronic Gulf, off the coast of the ancient Attica and Megaris. Its length is about 10 miles, and its greatest breadth nearly the same; but owing to the irregularity of its outline the entire area is not more than 50 square miles. A deep bay indents its western coast, and thus gives the island something like a semicircular form. Between the island and the mainland lies the beautiful Bay of Eleusis, communicating with the sea at either end by a narrow strait. These channels are deep and not difficult of entrance, and the bay within is very safe; but in modern times the Bay of Salamis, on the west coast, has been preferred for a harbour. The island is rugged and barren, but some portions of it produce vines and olives. At one period it had large pine forests; whence its ancient name of *Pityrussa*. Salamis formed up to 620 B.C. an independent state; but about that period a contest arose for its possession between Athens and Megara, which was at length settled in favour of the former by the arbitration of Sparta. The island continued under the Athenian dominion till 318 B.C., when it received a Macedonian garrison; and in 232 Athens regained possession of it by purchase. The

Salayer
||
Salem.

chief towns were Old and New Salamis, the former on the south and the latter on the north-east coast. Salamis is chiefly remembered for the great naval battle fought here in 480 B.C., which secured the independence of Greece. It took place in the narrow channel to the east of the island; the Greek fleet under Themistocles was posted in front of New Salamis, the Persian armada was ranged along the opposite coast, with the immense army drawn up on the shore behind them, and King Xerxes enthroned on a lofty promontory to view the anticipated victory. But the event disappointed his expectations; the vast numerical superiority of the Persians was of no avail, for want of sea-room, against the skill of their foes; the magnificent fleet was totally destroyed, and barely succeeded in conveying the monarch home in safety. A trophy was erected on the most easterly point of the island to commemorate the victory.

SALAYER, a group of islands in the Indian Ocean, off the S.E. promontory of the island of Celebes, between S. Lat. 5. 40. and 6. 20., E. Long. 120. and 121. The principal island Salayer is about 40 miles long by 8 broad on an average. It is traversed from N. to S. by a ridge of hills, densely wooded, and haunted by deer. The low land at their foot is cultivated, and produces millet, the chief food of the inhabitants, and cotton, which is made into coarse cloth. The island is dependent on the Dutch, and belongs to their province of Macassar. Pop. 20,000. The other islands are small and mostly uninhabited.

SALE, GEORGE, a learned orientalist and translator of the *Korân*, was born in the county of Kent 1680. Little is known regarding his private life. He was educated at King's School, Canterbury. He followed the profession of a lawyer, and was one of the founders of a society for the encouragement of learning begun in 1736. He was a valuable contributor to the *Universal History* of Swinton and others, and one of the authors of the *General Dictionary*, to which he contributed much of the translation from Bayle. The work by which Sale is now alone remembered is his English version of the *Korân*, translated from the original Arabic, with notes and quotations from approved commentators, and a learned preliminary discourse, London, 1734, 4to. He died in London on the 14th November 1736. Sale's oriental manuscripts were purchased after his death for the Radcliffe Library, Oxford, where they now lie.

SALEM, a district of British India, in the presidency of Madras, bounded on the N. by the Rajah of Mysore's dominions and the northern division of Arcot, E. by the southern division of Arcot, S.E. and S. by Trichinopoly, S.W. and W. by Coimbatore and Mysore; and lying between N. Lat. 11. 2. and 12. 54., E. Long. 77. 32. and 79; area, 7499 square miles. The western part of the district is mountainous, being occupied by several ranges, some of which rise to a height between 5000 and 6000 feet above the sea. The principal river is the Cauvery, which flows along the western and south-western frontiers of Salem for 140 miles. Another river is the Tyromany, which, like the former, flows into the Bay of Bengal. There are no lakes, but numerous tanks and ponds in the district. The climate is various in different parts of the country, but in general it is salubrious. Iron is the most important mineral production; and cotton, coffee, indigo, sugar, and tobacco are cultivated. Pop. 1,195,377.

SALEM, the capital of the above district, in a valley formed by the Sheevaroy Hills on the N., and a smaller ridge to the S., on the Tyromany, 170 miles S.W. of Madras. The valley is studded with tanks, as well as with a great number of wells; and being thus plentifully irrigated, the soil is highly cultivated. Salem itself is a fine specimen of a native Indian town, having broad streets planted with rows of cocoa-nut trees, and some of them lined with handsome houses two storeys in height. Here is an old fort, a jail, and many handsome inns. Salem is the principal seat of

VOL. XIX.

Salem
||
Salerno.

the Indian steel manufactory, which is carried on by a process of great ingenuity, proceeding upon a very recondite theory. It appears to have been practised from a remote antiquity; and probably the hieroglyphic carvings on the ancient Egyptian monuments were executed with Indian steel, as no other nation at that period was acquainted with the article. Pop. of the town (1843), 19,021.

SALEM, a city and seaport of the United States of North America, Massachusetts, on a projecting tongue of land, 14 miles N. by E. of Boston. The peninsula on which it stands is about 2 miles in length and three-quarters of a mile across; and its position is somewhat low. The streets are irregular, but many of the buildings very handsome. Chestnut Street, which is the finest, has a beautiful row of shady elms; and Washington Square, a large public park, is also planted with trees. The principal buildings of the place, which are in general very handsome, are the city-hall, court-house, custom-house, market-house, mechanic hall, athenæum, alms-house, and jail. There are many excellent public schools in the town; and in 1852 the total number was 27. The manufactures of the place are very important, and include a large cotton factory, and manufactories of chemical substances, machinery, black and white lead, sperm oil, candles, cordage, leather, and other articles. There are many banks, insurance offices, and newspaper offices in the town. The trade and navigation of the place are still important, though not so extensive as they were at a former period of its history. In December 1852 the shipping of the port had an aggregate tonnage of 50,455. The number of vessels that entered from foreign ports in the year ending June 30, 1852, was 448, tonnage 40,721; of those that cleared for foreign ports the number was 437, tonnage 40,084. Much of the trade of Salem has been absorbed by the ports of Boston and New York. Next to Plymouth, Salem is the oldest town in New England. It was founded in 1626, and soon embarked in the fisheries and coasting trade. Before the American revolution it had acquired a high place among the commercial towns of America; and it opened up the trade with many different countries in all quarters of the globe. On the breaking out of the war with the mother country, Salem eagerly embraced the cause of liberty; and in the course of seven years (1776-83) fitted out no fewer than 158 privateers, many of which became the terror of the seas. After the close of the war most of these vessels were turned into Indiamen. Pop. (1850) 20,263; (1853) about 22,500.

SALEMI, a town of Sicily, occupying a beautiful situation on a hill, in the province and 20 miles S.E. of Trapani. It is fortified, and has a large number of churches and convents; but the inhabitants are chiefly distinguished for laziness and dirt. There is no manufacture or commerce here. Salemi is believed to occupy the site of the ancient Halycæ. Pop. 8000.

SALEP, a sort of gum and starch extracted from the bulbs of the orchis. It is imported from the Levant in considerable quantities, particularly from Smyrna and Constantinople, and large imports of it find their way into the Indian bazaars from Affghanistan and Persia. This substance is said to be particularly nourishing, and is more palatable than sago or arrow-root. It is prepared by powdering the salep in a brass mortar, and making a solution with hot water.

SALERNO, a town of Naples, the seat of an archbishop, and capital of the province of Principato Citra, in a beautiful country at the foot of a branch of the Apennines, at the head of the Gulf of Salerno, 30 miles S.E. of Naples. The older parts of the town are ill and irregularly built, with narrow, dirty streets; but the Marina or quay, which was built by the French, forms a fine promenade, extending for about a mile along the shore. The principal edifice is the cathedral, which has been so much repaired and

Sales.

altered in modern times that it exhibits a most singular combination of different styles of architecture, of the ancient and of the modern. It was founded in 1084 by Robert Guiscard, who did not hesitate to plunder the ruins of Pæstum in order to enrich it, nor to employ the heathen sculptures to embellish this Christian fane. Hence the singular appearance of the tombs of some of the archbishops, adorned with the "Triumphs" of Bacchus and Ariadne, and the "Rape of Proserpine." In the crypt lies, according to the tradition of the church, the body of St Matthew. Other celebrated and probably more authentic tombs are also to be seen here,—of Hildebrand, Pope Gregory VII. (who died here in exile), of the second wife, the son, and the grandson of Robert Guiscard. Of the many other churches in Salerno none are very remarkable, nor are there any other buildings of much interest. The lyceum is said to be one of the best schools in the kingdom, and has inherited from the former university the privilege of conferring degrees. The port was once very good; and is well sheltered, but now almost useless from the accumulation of sand. A fair for cattle and other goods is held here annually in September; and is resorted to by great numbers of the peasantry, exhibiting a most picturesque variety of costumes. The ancient *Salernum* occupied the same site, or rather stood on the hill behind the modern town, where the ruins of the mediæval citadel are still to be seen, and where some antiquities have been dug up. A fort seems to have stood here before it was colonized by the Romans, 194 B.C.; but its previous history is unknown. Indeed, the only notable circumstance in its ancient annals is its capture during the Social War by the Samnite general Papius. It was, however, a place of consequence under the empire, and appears to have been frequented as a watering-place. But it was not till after the fall of the Western Empire that Salerno rose to its height. It passed first into the hands of the Goths, then into those of the Lombards, from whom it was taken by the Saracens in 905; but fifteen years after, it was recovered by the Greek emperor, and subsequently reverted to the Lombards. In 1076 Salerno was taken, after a siege of eight months, by Robert Guiscard; and thenceforward became the capital of the Norman possessions south of the Apennines. It is described at this period as remarkable for its amenity and its splendid palaces, its fruits and its wine, the beauty of its women, and the honesty of its men. The celebrated school of medicine, the first that arose in the darkness of Europe, was then in the zenith of its prosperity, under the patronage and protection of the Norman dukes. The university existed till 1817, when it was replaced by the present lyceum. At Salerno, in 1127, the kingdom of Naples was founded by the election of Roger II. to the crown. In 1193 the town was destroyed by the Emperor Henry VI.; but from this blow it soon after recovered. Its course, however, has been in modern times one of decline to its present condition. Pop. (1848) 16,000.

SALES, SAINT FRANÇOIS DE, Bishop of Geneva, and son of François, Count of Sales, was born at the castle of Sales, near Anneci in Savoy, on the 21st August 1567. He had his early education at La Roche and Anneci, and subsequently at the Jesuits' college at Paris. Leaving the capital in 1584, he went to Padua, to study civil law under the eminent legal professor Guy Panciroli. Here his progress was attended with the most marked success; and after spending some time in travel in Italy, he returned to the old castle of Sales with a high reputation for learning and piety. His father was induced by his kinsman, Louis de Sales, canon of Geneva, to abandon a project which he had formed of appointing him counsellor of Chambery, and through that churchman's mediation he was permitted to become a preacher. The success of De Sales in this sphere was quite astonishing. His strikingly

handsome figure, his powerful and pleasing voice, his modest and mild demeanour, combined with an earnestness which thrilled and a vivacity which engaged his audience, proved how well he was adapted for the business of religious conversion, and how deep had been his self-knowledge in courting such a sphere of labour. He accordingly set out with his clerical kinsman to convert the city of Geneva from the faith of Calvinism to that of the Church of Rome. By dint of eloquence and of gold, he is said to have succeeded in three years in the conversion of no less than 800 persons. On the return of François to Anneci in 1596, he was made coadjutor to the Bishop of Geneva, with the title of Bishop of Nicopolis in *partibus infidelium*. The king, anxious to retain him in France, offered him the first bishopric that might become vacant, but he politely refused. The death of the Bishop of Geneva raised him to that important office on the 8th December 1602; and he was no sooner consecrated than he made himself felt to the remotest corner of his see, by the vigour of his reforms and by the mild charity of his mandates. In 1605 he had the honour of refusing a cardinal's hat. His *Introduction to a Religious Life* appeared in 1607. It will be seen from this work that the man who is eloquent and persuasive in speech is very likely to be neither when he assumes the pen. The work is characterised throughout, however, by the most unaffected piety. In 1610 De Sales founded the Order of the Visitation, and placed over it Madame de Chantal, a particularly fervid lady, who was sister to the Archbishop of Bourges. The work in which the good Bishop of Geneva had been so long engaged was now destined to pass into other hands. After preaching on the Christmas Eve of 1622, he was seized with an attack of paralysis, which closed his days on the 28th of December 1622.

We are indebted to Camus, Bishop of Bellay, for the very interesting work *The Spirit of François de Sales*. The best edition of his works is that of Paris, 1641, 2 vols. folio. He was canonized on the 29th of January 1665 by pope Alexander VII.

SALFORD. See MANCHESTER.

SALIC or **SALIQUE LAW** (*Lex Salica*), an ancient and fundamental law of the kingdom of France, usually supposed to have been made by Pharamond, or at least by Clovis, in virtue of which males only are to inherit. Some, as Postellus, would have it to have been called *Salic*, as if *Galla*, because peculiar to the Gauls. Montanus insists that it was so named because Pharamond was at first called *Salicus*. Others will have it to be so named as having been made for the Salic lands. These were noble fiefs which the first kings used to bestow on the Saliens; that is, the great lords of their *salle* or court, without any other tenure than military service; and for this reason such fiefs were not to descend to women, as being by nature unfit for such a tenure. Some, with more probability, derive the origin of this word from the Saliens, a tribe of Franks that settled in Gaul in the reign of Julian, who is said to have given them lands upon condition of their personal service in war. He passed the conditions into a law, which the new conquerors acquiesced in, and called it *salic*, from the name of their former countrymen. (See FRANCE.)

SALIERI, ANTONIO, a celebrated composer, was born at Legnano, in the state of Venice, on 19th August 1750. In his boyhood he was taught the violin by his elder brother, a good pupil of Tartini, and the harpsichord by Simoni, organist of the cathedral of Legnano. When fifteen years old he lost his father, and repaired to Venice, where one of the Mocenigo family patronised him. He received lessons in composition from Pescetti of St Mark's cathedral, and lessons in singing from Pacini, one of the chapel tenors. Gassmann, master of the imperial chapel at

Salford
||
Salieri.

Salii
||
Salins.

Vienna, came at that time to Venice, and accepted Salieri as a pupil at the request of Giovanni Mocenigo. On 15th June 1766 Salieri followed Gassmann to Vienna. Gassmann treated him with great kindness and generosity, benefits which he was afterwards able to repay to Gassmann's two infant daughters when they were left destitute by their father's death. Under Gassmann Salieri made rapid progress in composition. In 1770 he produced his first opera *Le donne letterate*, which was well received. Several others followed with great success, especially the serious opera *Armida*, which delighted by the beauty of its melodies. Gassmann dying in 1774, Salieri, in 1775, succeeded him as imperial chapel-master. At this time Salieri being struck by Gluck's compositions, began to study the works of that great master, and also received instructions from him. In 1778-1780 he composed operas for Milan, Venice, and Rome. In 1781 Gluck having become aged and infirm, and feeling unable to set to music the French libretto of *Les Danaïdes*, for which he had been engaged at Paris, entrusted the composition of the music to Salieri. In 1784 Salieri carried *Les Danaïdes* with him to Paris, where it was performed with the greatest applause as a composition of Gluck until the thirteenth representation, when Gluck publicly declared Salieri to be the sole composer of the music. Returning to Vienna, he composed several operas between 1784 and 1787, and in the latter year his opera of *Tarare* was performed at Paris with great success. He was called upon the stage and crowned; the first time that such an honour was bestowed on an operatic composer. After his return to Vienna in that year he composed fourteen operas, the last of which was performed in 1804. Among his operas, *Les Danaïdes* and *Tarare* are reckoned the finest. In some points he was pre-eminently skilful as a dramatic composer, so that such men as Beethoven and Meyerbeer considered it an honour to receive his advice. In 1824, aged seventy-three, he obtained leave to retire from his avocations, and received a grant of his entire salary for life. He died on the 12th May 1825. A requiem which he had composed for his own death was performed on the occasion of his funeral. He was married and left several daughters. He bore the titles of Foreign Member of the French Institute, Member of the Royal Academy of Fine Arts, Foreign Correspondent of the Paris Conservatory, and Member of the Royal Academy of Music at Stockholm. Interesting details regarding Salieri's private and artistic life are contained in Herr Edler von Mosel's work *Ueber das Leben und die Werke des Anton Salieri. Wien, 1827*. Salieri's compositions for the church were five masses, one requiem, three Te Deums, and several other pieces. He composed three oratorios and eight cantatas; forty-six operas, and a great number of detached pieces of vocal music with accompaniments; two collections of fifty canons for voices alone, and one hundred and fifty compositions of the same kind in MS; a book of instruction in singing, one concerto for the organ, two do. for piano, 1 do. for flute and oboe; two symphonies; several serenades and some ballet-music; twenty-four variations for orchestra upon the subject of the *The Spanish Folly*. (G. F. G.)

SALII, priests of Mars, of which there were twelve, corresponding to the twelve ancilia or shields of which they had the care, were instituted by Numa, and wore parti-coloured garments and high bonnets, with a steel cuirass on the breast. They were called *salii*, from *sal-tare*, to dance; because, after assisting at sacrifices, they danced along the streets, with bucklers in their left hand and a rod in their right, with which they struck on one another's bucklers, and sang hymns in honour of the gods.

SALINS, a town of France, in the department of Jura, picturesquely placed at the head of a beautiful valley, in a

gorge between two mountains, 26 miles N.E. of Lons-le-Saulmer. It is encircled by walls, and defended by two forts on adjacent heights. Most of the buildings are new and substantial, as the town was almost wholly destroyed by fire in 1825. There are many churches, a large college theatre, barracks, and jail. But the largest establishment in the town are the salt works (*Saline Royales*), which give the place its name. These are about 300 yards long by 100 broad, and are inclosed with an embattled wall. The salt is obtained from springs, which are supposed to have been used as early as the time of the Romans. Brandy, leather, and sulphate of soda are also made here; and there is some trade in wine, brandy, cheese, honey, salt, timber, gypsum, &c. Pop. 7481.

SALISBURY, or NEW SARUM, a municipal and parliamentary borough of England, capital of Wiltshire, in a low, rich country, at the confluence of the Avon, Willy, and Bourne rivers, 82 miles W.S.W. of London. It is very regularly built, six principal streets stretching from N. to S., and as many others crossing them at right angles. Through some of the streets streams of water from the Avon are conducted in artificial channels. The houses, which are large, and some of them very handsome, are generally built of brick; but some, of a more ancient date, are of wood. The chief building is the cathedral, which rises majestically to the south of the town, from the close and beautiful meadow, about half a square mile in extent, planted with trees, and entered by three antique gates. The building itself is one of the finest and most regular in England; it is in the form of a double cross, from the centre of which rises a graceful spire, the loftiest in the country, being 404 feet, equal to the height of the cross of St Paul's, London. Salisbury cathedral is in the early English style, and was built, with the exception of the spire and west front, which are later, between 1220 and 1258. It is very complete in all its parts, having a nave and choir, with two aisles; a lady chapel, east of the choir; a larger and a smaller transept, with one aisle each; besides an octagonal chapter-house, the roof supported by a single elegant pillar, and cloisters 181 feet square. Within the close stands also an extensive episcopal palace, and a deanery with fine gardens. The principal dimensions of the cathedral are as follows:—Extreme length, 474 feet; length of great transept, 230 feet; of nave, 229 feet; height of the interior, 81 feet; of the exterior, 115 feet. The west front is a very rich and fine specimen of the pointed style, flanked by massive square towers surmounted by pinnacles. According to an old Latin epigram, the cathedral has as many windows as days in the year, as many pillars as hours, and as many gates as moons. Many of the monuments are interesting, and some more ancient than the building itself, having been transferred from the former cathedral at Old Sarum. Salisbury has, besides the cathedral, two parish churches and a chapel of ease; also places of worship for Independents, Baptists, Roman Catholics, Wesleyan and Primitive Methodists. There is a grammar school attached to the cathedral for the instruction of the choristers, and another founded by Queen Elizabeth in the town. There are, besides, a bishop's school and various others of different kinds. In the middle of the town is a large open market-place, at one corner of which stands the council-house, a building of brick with a handsome stone portico in the Grecian style. Near this is the poultry market, containing a fine hexagonal cross of the time of Edward III. Salisbury contains also a county jail and bridewell, library and reading-room, museum, assembly and concert rooms, a small theatre, and several charitable institutions. Races are held annually in August, on the downs near the town. No important manufacture is carried on here. Much woollen cloth was once made, but that branch of industry has become extinct; the manufacture of cutlery is now the only one that is pur-

Salisbury.

Sallee
||
Sallustius
Crispus.

sued. There is some traffic in the produce of the surrounding country, which is disposed of at weekly markets and annual fairs. The borough is governed by a mayor, six aldermen, and eighteen councillors, and returns two members to Parliament. Salisbury owes its origin to a quarrel which took place in the thirteenth century between the bishop and canons of Old Sarum and the captain of the castle, in consequence of which these ecclesiastical dignitaries left their former seat, about a mile and a half north of Salisbury, and founded a new cathedral here. The most of the townsmen followed them; and hence the name of New Sarum applied to the town. A charter was granted by Henry III., and the town was walled in 1315. Salisbury has been honoured by several visits of royalty, and more than one Parliament has been held here. Pop. of the borough (1851), 11,657.

SALLEE, or SLA, a seaport of Morocco, on the Atlantic coast, at the mouth of the Bu Regreb, on its northern bank, opposite to Rabatt on the southern; N. Lat. 34. 3., W. Long. 6. 50. It is strongly fortified, but not very well built; there are several batteries which command the entrance to the river. It has a harbour, roadstead, magazines, and marine arsenal; and is the principal station of the fleet of Morocco. As a commercial town, it is still thriving, though a portion of the trade has been transferred to Mogadore. Sallee was once notorious as a haunt of pirates, but this is no longer the case. Carpets are made here. In the vicinity are many fine gardens. Pop. 25,000.

SALLUSTIUS CRISPUS, CARUS, a celebrated Latin historian, was born of a plebeian family of Amiternum, a city of the Sabines, B.C. 86, the same year that Marius died. We can have no doubt that the cultivation of his mental powers must have been carefully attended to, though this does not seem to have prevented him from falling into all the extravagances and dissipation of a profligate age. His intrigue with Fausta, daughter of Sulla, and wife of Milo, became known to her husband, and was punished in a way which made the two parties irreconcilable enemies. Sallust became quæstor at the age of twenty-seven, and tribune of the people in the year B.C. 52. His profligacy, however, became so notorious that the censors Appius Claudius and L. Piso, B.C. 50, found it necessary to remove him from the Senate, though his removal has been ascribed by others to political reasons, as he was a warm supporter of Cæsar. It is supposed that he at this time wrote his account of the conspiracy of Catiline. His absence from public affairs continued only for a short time, as we find him prætor B.C. 47, when he accompanied Cæsar to Africa; and after the battle of Thapsa he was appointed to the province of Numidia, where he enriched himself by the most nefarious means. He returned to Rome with immense wealth; and after the murder of Cæsar abstained from taking any part in public affairs. He again devoted himself to a life of pleasure, and constructed a magnificent palace on the Quirinal, in the midst of gardens which were afterwards known as the Horti Sallustiani. This palace was subsequently occupied by Vespasian, Nerva, and many other emperors, and was destroyed by fire when Rome was plundered by Alaric. According to Eusebius, Sallust was married to Terentia, wife of Cicero; but this story is improbable. He died B.C. 35, in the fifty-first year of his age, being not less distinguished for his talents than for his profligacy. Of his historical works the following remain:—*Bellum Catilinarium*, a history of the conspiracy of Catiline, B.C. 63, with a very beautiful introduction, in which he laments, with much apparent feeling, the corruption of the age, and the profligacy of his contemporaries; *Bellum Jugurthinum*, a history of the wars carried on against Jugurtha, King of Numidia, which he was probably induced to write from his residence in that country; *Historiarum*

Libri Quinque, a work on the history of Rome, from the consulship of M. Æmilius Lepidus and Q. Lutatius Catulus, B.C. 78, to that of M. Æmilius Lepidus and L. Volcatus Tullus, B.C. 66, with an introduction on the manners and government of Rome, and a short summary of the wars of Marius and Sulla. Of this work only a few fragments have been preserved. Some other works, however, have come down to us which are ascribed to Sallust, though without sufficient reason; *Dux Orationes de Respublica Ordinanda*, addressed to Julius Cæsar when he was proceeding against Petreius and Afranius in Spain; and *Declamatio in Ciceronem*, which is alluded to by Quintilian. The character of Sallust as a historian stood high among the ancients, who regarded him as the rival of Thucydides, and in many points he was certainly the imitator of that writer. Like Thucydides, he endeavours to give the causes of the various events which he is narrating; and if he more frequently ascribes them to unworthy motives, we may readily discover the reason of this in the corruption of the age in which he lived. But they both show themselves profound thinkers, and intimately acquainted with the springs of human action. The first edition of the works of Sallust was published in Rome in 1470, and in Venice the same year; but since that time a variety of impressions have appeared. A very excellent edition is that of C. H. Frotcher, giving the notes and emendations of Cortius, 3 vols., Lips. 1830. The translations are numerous. It has been done into German by Gerlach (1827); into Spanish, by the son of the king (1772); into Italian, by Alfieri; and into French, by De Brosses. The oldest English version is by Barclay (1511), and since his time no less than fourteen writers have executed translations of Sallust. The best are those of Gordon (1774), Rose (1751), Murphy (1807), Peacock (1845), and Watson (1852). Gerlach (1823), Kritz (1834), and Dietsch (1846), have published the best texts of Sallust.

SALMASIUS, CLAUDIUS, the Latinized form of CLAUDE DE SAUMAISE, a very learned man of the sixteenth century, was born of a noble family at Sémur in Auxois, on the 15th of April 1588. He received his early education in Latin and Greek from his father, who had himself translated the work of Dionysius of Alexandria into French verse, Paris, 1597. At the age of ten he is reported by his ancient eulogist, Antoine Clement, to have been able to read Pindar with fluency and correctness. At the age of sixteen he sought Paris, to complete his studies, where he became acquainted with the celebrated Casaubon, through whose influence, it is said, he was led to embrace Protestantism. Young Saumaise now sought Heidelberg, and was favoured with an introduction from his friend Casaubon to the great jurist Denis Godefroy. He prosecuted his studies with uncommon diligence during his stay in Germany, and was exposed to a severe illness from over-exertion. For a considerable time he had been accustomed to devote every third night entirely to study. He published in 1608 his first work, consisting of two books of Nilus, Bishop of Thessalonica, and that of a monk Barlaam, both on the supremacy of the Pope, enriched with corrections and notes. Next year he dedicated to the eminent Latin scholar Gruter an edition of Florus. Shortly after his return to France he published, in opposition to Sirmondus, *De Suburbicariis Regionibus et Ecclesiis*; in 1620 his *Historiæ Augustæ Scriptores Sex* appeared; and two years afterward he published his edition of Tertullian's work *De Pallo*. In 1623 Salmasius married, and was engaged for many years in the neighbourhood of Paris on his great work, which first appeared in 1629, in 2 vols., under the title of *Plinianæ Exercitationes in Cui Julii Solini Polyhistor*. This was a work of astonishing erudition, but written in a rambling, confused style. It possessed all the blemishes and all the excellences of his previous writings. It exhibited great carelessness as to the

Salmasius.

Salmon
Fishery
||
Salonica.

correct statement of facts, and displayed much arrogance and pretension. The publication of this work raised his reputation to its highest pitch; and he received the solicitations of various European princes to settle in their dominions. He finally retired to Leyden in 1632 to an honorary professorship. Salmasius had numerous tempting offers from Cardinals Richelieu and Mazarin to return to France; but he continued to reside in Leyden till 1650, when he visited Queen Christina of Sweden, who is reported to have written "she could not be happy without him." The climate of this northern kingdom not agreeing with him, Salmasius returned to Holland, to comply with the request of Charles II. of England to write a defence of his father and of monarchy. Salmasius accordingly published his *Defensio Regio Carolo I.* in 1649, but had not calculated on so powerful a hand as John Milton's being raised against him. The *Defensio pro Populo Anglicano* entirely eclipsed Salmasius in passionate logic, vehement rhetoric, and profound scholarship; and the unfortunate Frenchman, pampered by kings and fondled by princes, is said to have taken this withering exposure so much to heart that it cost him his life. He died in September 1653, while engaged on a reply to Milton.

In addition to the works already mentioned, Salmasius wrote and edited the following works:—*Notæ in Pervigilium Veneris*, Ley. 1638; *De Usuris*, Ley. 1639; *De Modo Usurarum*, Ley. 1639; *Dissertatio de Fœnore Trapezetico*, Ley. 1640; *Commentarius in Simplicii Enchiridion Epicteti*, Ley. 1640; *Interpretatio Hippocratei Aphorismi de Calculo*, Ley. 1640; *De Hellenistica Commentarius Controversam de Lingua Hellenistica Decidens*, Ley. 1645; *Observationes in Jus Atticum et Romanum*, Ley. 1645. Antoine Clement prefixed a Life of Salmasius to his Letters, which were published at Leyden in 1656.

SALMON FISHERY. See **FISHERY.**

SALO, a town of Austrian Italy, Lombardy, in a beautiful region at the head of a bay of the same name on the west shore of the Lake of Garda, in the province and 15 miles E.N.E. of Brescia. It is well built, partly on piles, and contains several churches, a nunnery, school, theatre, and hospital. It is the seat of a court of justice, and has manufactories of thread and of silk, which are considered the best made in Italy. Groves of olives, oranges, citrons, and mulberries encircle the town, and the heights of Mount San Bartolomeo overhang it. Pop. (1846) 4531.

SALON, a town of France, in the department of Bouches-du-Rhone, in a plain rendered luxuriantly fertile by irrigation, 29 miles N.N.W. of Marseilles. There is a neat modern quarter surrounding the old town in the centre, and separated from it by a well-planted boulevard. Some of the houses in the old town are good, and there are two curious ancient churches, one of which contains the remains of the celebrated Nostradamus. On a height at one end of Salon stands the castle of this astrologer, now a barrack. Silk, hats, soap, and olive oil are made here; and the trade of the place is considerable. Pop. 5617.

SALONICA, or **SALONIKI** (anc. *Thessalonica*), a town of European Turkey, Macedonia, capital of an eyalet of the same name, at the head of the Gulf of Salonica, the ancient Thermaic Gulf, 315 miles W.S.W. of Constantinople. From the noble and almost land-locked bay, up the side of a steep hill, rises the town—domes, minarets, and cypress trees,—encircled by lofty whitewashed walls, to the seven-towered citadel on the summit. From this point two ravines diverge in a semicircular direction, and stretch down to the sea, inclosing the city between them. The walls, which are built on ancient Cyclopean and Greek foundations, are about five miles in circuit. The interior presents that wretched and irregular appearance that is characteristic of Turkish towns; hovels of unburnt brick, and bazaars consisting of long narrow streets, shaded with

vine-covered trellises and branches of trees, or obstructed with projecting wooden sheds, stand side by side with the large and magnificent piles erected in ancient or mediæval times. A long street intersects the town from east to west, spanned at either end by a triumphal arch. This is the ancient Egnatian road, the highway between the western and the eastern capitals. Some of the mosques are very ancient, and have witnessed in successive ages the rites of pagan, Christian, and moslem worship performed within the same walls. One of these is circular, like the Pantheon at Rome, and covered with mosaics on the inside. Another was originally consecrated to the Thermæan Venus; and did not the modern arrangement of the building somewhat conceal and disfigure its beauty, it would stand out as one of the most perfectly-preserved monuments of antiquity. A Corinthian colonnade, surmounted with large and beautiful figures in high relief, is supposed to have been the entrance to the hippodrome, and has received from Jewish superstition the name of *Las Incantadas*, on the idea that these are human figures magically turned to stone. The hippodrome or race-course itself is a large area near the middle of the town. Of mosques, originally Christian churches, one bears the name, and is built after the model, of St Sophia at Constantinople, though of smaller size; and another, the former metropolitan church, is lined in the interior with marble, and adorned with pillars of *verd antique*. There are several Greek churches and convents, one Roman Catholic church, Jewish synagogues, baths, and *khans*. Salonica is the seat of a general governor and of a Greek archbishop. The manufactures of the town are of considerable importance, including weaving, dyeing, carpet-making, silk-spinning, the manufacture of hardware, &c. But the introduction of European goods has proved detrimental to the industry of the place. As a commercial town, Salonica is, among Turkish ports in Europe, second only to the capital. Corn, cotton, silk, and tobacco are the principal articles exported. The following table exhibits the navigation and trade for each year from 1848 to 1851:—

Salonica.

Year.	Entered.		Imports.	Cleared.		Exports.
	Vessels.	Tons.		Vessels.	Tons.	
1848	643	70,565	332,782	578	69,887	239,942
1849	566	65,103	345,638	548	66,358	214,728
1850	514	62,964	318,879	550	64,278	257,254
1851	509	59,756	427,920	522	61,174	179,373

In 1856 the navigation and commerce of the port was thus divided among the various nations:—

Flags.	Vessels.	Tonnage.	Imports.	Exports.
			L.	L.
Greek.....	266	15,067	33,400	27,200
Turkish.....	150	11,528	52,000	46,500
Austrian.....	90	32,098	732,500	398,800
British.....	62	21,078	221,000	640,500

Norwegian.....	2	438	...	2,900
Total.....	659	101,680	1,101,800	1,400,700

The country about Salonica is exceedingly beautiful. Amid groves of cypresses and other trees stand many elegant residences of the consuls of foreign countries; and the view over the gulf is very fine, the snowy heights of Olympus rising in the distant west. Near the town are sulphurous springs. Salonica was very much injured by conflagrations which took place in 1856 and 1857. Nearly

Salop
||
Salt.

half of the inhabitants are Turks, the rest of the population being nearly equally divided between Greeks and Jews. Pop. about 70,000. (See THESSALONICA.)

SALOP. See SHROPSHIRE.

SALSETTE, an island of British India, north of that of Bombay, from which it is separated by a narrow strait, between N. Lat. 19. and 19. 18., E. Long. 72. 54. and 73. 3.: length, from N.E. to S.W., 18 miles; breadth, about 10; area, 150 square miles. It is a strikingly diversified and very picturesque land, with woody hills, gray rocky mountains, and gloomy caves, the haunts of wild beasts; rich valleys, broad rice-fields, tall graceful cocoa-nut palms, and meadows on which cattle graze. In various parts of the island, and especially at Keneri, near the centre, there are ancient rock-cut caves. Salsette formed part of the province of Aurungabad under the Mogul emperors, but fell into the hands of the Portuguese soon after their settlement in India. In 1739 it was conquered by the Mahrattas, and in 1774 came into the possession of the British. It forms part of the district of Taunah, so called from the chief town on the island. It is connected with Bombay island by a causeway, and traversed by the Great Indian Peninsular Railway, which crosses over on a viaduct to the mainland. Pop. estimated at 50,000.

SALT, a compound of chlorine and sodium, known in chemical language as *chloride of sodium*. Its symbol is Na Cl, and its equivalent 58.5. It is the only mineral food of man, and forms an essential constituent of the blood, the loss of saline particles therefrom by the secretions, the tears, the bile, &c., being repaired by the use of common salt as a condiment. The gastric juice of the stomach contains free hydrochloric acid, which is doubtless derived from the salt taken with food; while the blood and some of the secretions contain soda, also referable to the same source. The unwholesomeness of salted provisions is probably due rather to their hardness and indigestible nature than to the salt with which they are impregnated.

The use of salt must have been nearly coeval with man's existence on the earth, frequent references to it, or to customs connected with it, occurring in the sacred writings.

All animals appear to be more or less fond of salt; even bees will sip a solution of it with avidity. Mungo Park says that in the interior of Africa, "the greatest of all luxuries is salt. It would appear strange to a European to see a child suck a piece of rock-salt as if it were sugar. This, however, I have frequently seen; although in the inland parts the poorer class of inhabitants are so very rarely indulged with this precious article, that to say a man eats salt with his victuals is the same as saying he is a rich man. I have myself suffered great inconvenience from the scarcity of this article. The long use of vegetable food creates so painful a longing for salt that no words can sufficiently describe it." (*Travels*, i. 280.) Burchell, in his *Travels in South Africa*, states that he had to send 90 miles for a gallon of salt, which he and his party regarded as a "valuable and important acquisition."

Salt exists in inexhaustible quantities in the waters of the ocean, in the proportion of about 2.7 per cent., or nearly 4 oz. per gallon, or a bushel in from 300 to 350 gallons. Salt is also found in immense masses of what is called *rock-salt*, or *sal gem*, in rocks of all ages, but chiefly in the new red sandstone, or saliferous formation, or the *trias*, where it is associated with a set of red sandstones and pebbly conglomerates, yellow magnesian limestones, and variegated shales and marls, which inclose irregular masses of rock-salt and gypsum. The following section (fig. 1) represents the deposit at Wimpfen in Wirtemberg, where the gypsum is inclosed by a deep layer of shell limestone containing the rock-salt as a separate mass. There are considerable difficulties in accounting for these deposits, but the discussion of them belongs to GEOLOGY.

The subterranean streams of water percolating through saliferous strata become impregnated with salt, and give

Salt.

Fig. 1.

rise to *brine springs*, so abundant in the great plain of the red marls and sandstones of Cheshire. The salt is not uniform in extent, but occupies limited areas. The brine springs occur at various depths. At Nantwich the brine is met with about 10 or 12 yards from the surface; and in sinking for fresh water, caution is required to avoid the brine. At Winsford it is generally necessary to sink from 55 to 60 yards before it is met with, and it then rises to within 12 yards of the surface. It occurs at other places at various depths. Droitwich in Worcestershire furnished salt from its brine springs in the time of the Romans; and it is probable that the supply was procured from such springs as found their way to the surface. In the time of Edward the Confessor, as appears from Domesday-Book, brine pits were wrought at all the wiches in Cheshire. We read of several attempts made to improve the manufacture; and soon after the formation of the Royal Society reports of the methods of manufacture were published by that body. The salt made in England was long considered to be inferior to foreign salt; but at the commencement of the eighteenth century Parliament granted a reward to Mr Lowndes, a Cheshire gentleman, for improvements in the manufacture. In 1748 Dr Brownrigg published his *Art of Making Common Salt*, and by this time the manufacture had made some progress. The River Weaver was made navigable for vessels of large size from Northwich and Winsford to Liverpool, whereby means for distributing the salt of Cheshire were increased, and the manufacture gradually became important, the salt being distributed throughout the country, and also exported. About the year 1670 the beds of rock-salt, whence the springs originated, were discovered while searching for coal in Marbury, about a mile to the north of Northwich. They were found about 34 yards from the surface, in a bed 30 yards thick, resting on a stratum of indurated clay. It was afterwards found that, on sinking a shaft at any point within half a mile of Marbury, the salt was met with at the same depth. This was the only deposit discovered until 1779, when, in searching for brine near Lawton, it was met with about 42 yards from the surface in a stratum 4 feet in thickness; but on penetrating through the clay beneath it, a second stratum of rock-salt, 12 feet in thickness, was found. On continuing the sinking through 15 yards of clay, a third stratum of rock-salt was discovered, which was sunk into to the depth of 24 yards, the lowest 14 of which were found to be the purest. The existence of this pure salt at so great a depth induced the Northwich owners to sink deeper, which they had not hitherto done, for fear of meeting with fresh-water springs. Accordingly, in 1781, they passed through the indurated clay below the rock-salt which had so long been worked. Immediately below this clay, which was 10 or 11 yards in thickness, they came upon a second stratum of rock-salt, the upper portion of which was about equal in purity to the higher stratum; but on penetrating to the depth of about 25 yards it was found to be much more free from earthy admixture. This increased purity, however, only extended to 4 or 5 yards.

The strata passed through in sinking for brine or rock-salt are usually clay and gypsum, mingled in various proportions, the latter predominating in nearing the brine or

Salt. rock-salt. The miners (named *wallers*, from the bank or wall which they raise round the pit with the rubbish of the works) call the clay, according to its colour, *red*, *brown*, or *blue metal*, and the gypsum they name *plaster*. The strata are usually sufficiently compact to exclude fresh water; but in some places are so broken and porous (*shaggy metal*, as the wallers call it) as to lead to the discontinuance of the sinking. The use of the steam-engine in pumping, and improved methods of sinking, have, however, in modern times, obviated the difficulty. The accompanying section (fig. 2) of the Wharton salt-mine, on the River Weaver, will further illustrate the nature of the workings.

Fig. 2.

The different degrees of purity of the rock-salt are represented by a horizontal section of one of the beds, in which various irregular circular, oval, or pentagonal figures, varying from 2 or 3 to 10 or 12 feet in diameter, may be seen. The boundary-lines of these figures are white, and from 2 to 6 inches wide: they consist of pure rock-salt, while the other portions are of salt mixed with earth in varying proportions. In passing through the indurated clay or stone, small veins of rock-salt are found running in various directions; and wherever a crevice occurs it is filled up with rock-salt, to which the clay and oxide of iron have given a deep red tinge.¹

The rock-salt of Cheshire is obtained in masses of considerable size, differing in form and purity. They are separated by blasting, and with the aid of the usual tools. In extending the workings, a good roofing is secured for the intended cavity, and in doing this the men work horizontally with common picks, so as to leave a roofing of the rock as plane as possible. A few feet above the purer portion the

rock is of inferior quality, and is used in the refineries. The purer rock is called *Prussian rock*, from its being largely exported to the shores of the Baltic. The cavity thus formed, when illuminated by candles, presents a striking and brilliant appearance. In some cases pillars 8 or 10 yards square are left to support the roof; in others the salt is worked out in aisles. The salt is raised to the surface by steam-power, but horses are employed under-ground for conveying it to the bottom of the shaft. The shafts are usually square, and constructed of timber.

When, from any circumstance, water has reached a deposit of rock-salt, it forms a solution, and should the supply of water be constant, we thus have a brine spring. In order to reach it, a shaft is sunk down to a strong flag-stone over the brine; and in order to exclude fresh-water, a second inner shaft is formed, and space between the two filled with clay. When the clay puddle becomes solid the flag is broken, and the brine usually flows up the shaft. In Camden's time the brine was raised by human labour. He speaks of a "deep and plentiful brine-pit at Northwich, with stairs about it, by which, when the people have drawn the water in their leathern buckets, they ascend half-naked to their troughs, and fill them, from whence it is conveyed to the wick-houses." In places where a stream of water could be commanded, a water-wheel has been used for working the pumps; wind-mills and horse-power have been employed; but steam-power has now superseded all other methods of pumping.

The writer of this article has lately visited the salt-making town of Droitwich in Worcestershire, and will now describe the modes of manufacture adopted in that place, as a type of this branch of industry. The brine containing one-fourth of its weight of salt, rises from springs situated about 150 feet below the surface. A steam-engine is employed to pump it into reservoirs attached to each of the salt-works of the town, of which there are about five, producing about 60,000 tons of salt per annum. The reservoirs are large wooden cisterns, pitched within, or they may be ponds formed in clay and lined with brick. In Cheshire, where rock-salt is easily procured, a quantity is kept in the reservoir in order to ensure the saturation of the brine. The object of the manufacture is to evaporate the liquid portion of the brine in such a manner as to produce the variety of salt required. The different varieties were named by our Droitwich informant as follows:—*Fine* or *square salt*, the term square being due to the shape of the moulds; *Butter salt*; *brisk salt*; *basket salt*; *broad* or *coarse salt*; *bough salt*, made once a year in cold winter weather, and sometimes crystallized on boughs of trees, or on ornamental baskets, like alum baskets, for toys or presents; lastly, *agricultural salt*, consisting of the sweepings of the salt-works, and the deposit formed at the bottom of the evaporating pan.

The pans (fig. 3) used for evaporating the brine are made of wrought iron, and may contain from 600 to 1000 or more superficial feet: the usual form is that of an oblong square, and the depth from 12 to 16 or 18 inches. There are from two to four fires to each pan, according to its size; and the furnace extends far beneath the pan, and is so capacious as to require that iron supports should be fixed within it, on which the bottom of the pan rests. Thus, on looking into the furnace, the flames are seen to play around a number of short columns, spreading out at their bases and at their tops, so as to present a broad surface to the floor of the oven, and to the under part of the pan respectively. A supply of coal is kept near the fur-

¹ Engravings illustrative of the above descriptions are given in Mr Henry Holland's *General View of the Agriculture of Cheshire*; but the most complete and indeed the only separate work on salt is by Mr Charles Tomlinson, entitled *The Natural History of Common Salt*, published by the Christian Knowledge Society, 1850.

Salt. nace doors, and a man works with long-handled iron tools at feeding the fire, stirring and spreading the fuel, and

Fig. 3.

raking out the slag or clinkers. The fires are at one of the narrower sides of the oblong pan, and the flues conveying the heat into the drying-room (supposing the manufacture to be fine salt) are at the other; thus the two longer sides of the pan are left free for the operations of the work-people. For their convenience, the floor is raised, and presents a long walk on each side the pan, with a bench or a floor, with apertures, along side of it, where the moulds are set to drain. Standing on one of these raised walks, we watched the boiling of a panful of brine, which had been brought to the boil soon after daybreak, and was then (ten o'clock) ready for the moulds. The steam rose in dense white clouds to the roof, where it passed through apertures left for its escape, and the manipulators (in this case women) were bleached, by constantly living in an atmosphere of steam, to salt-like whiteness, but declared themselves to be perfectly healthy. The first step was slightly to lower the temperature of the boiling brine. This was effected by placing a wooden shoot beneath a tap in connection with the reservoir, and thus conveying into the pan a small quantity of cold brine, enough to check the boiling. Each woman now took a long-handled tool, which she called a *rake*, but which rather resembled the scrapers with which mud is collected in roads; this she flung forward towards the middle of the pan, and then dragged towards her, thus collecting the salt in large white heaps at the sides of the pan. The weight of the rake is so great as to make this a laborious part of the woman's work. At the back of the workers, ranged along beneath the side windows of the pan-room, stood a number of empty moulds or *tubs*, as the work-people call them. These are made of wood, and are of the well-known size and form of our *squares* of salt, or rather parallelopipeds. One of these moulds was now lifted into the pan, and set up on one of its narrow ends, which was perforated, the other being open. The woman now took a second long-handled tool called the *skimmer*, being a large iron disk, also perforated, and with which she lifted up masses of salt, and poured them into the mould. A few of these ladlesful seemed to fill the mould to the brim; but she took a short, thick stick, called a *rammer*, and worked the salt within the mould until it had subsided to half its former height, the brine meanwhile gushing out at every crevice. More salt was now poured into the mould, until a conical heap rose above the top; this was beaten down by a flat wooden tool called the *beater*, and was then lifted out of the pan and set aside to drain and consolidate. When all the salt had been thus removed from the pan and collected in moulds, fresh brine was added to that which remained in the pan, the fires were made up, and the boiling commenced anew. Such was the simple process of making fine or square salt, repeated at

each pan about three times daily. The consolidation of the salt was completed in a hot room, where the squares, released from their moulds, and trimmed by means of a smooth piece of wood called the *tapper*, were arranged on shelves, with small spaces between each, that the air heated by the flues might have free access to them. The quantity of salt made at one pan, and that not the largest, amounted to about twenty tons per week.

The form of the salt-crystal obtained by slow spontaneous evaporation is a solid cube; but when procured at a boiling heat from the surface of the solution, the crystals are very small, and collect together in groups in hollow four-sided pyramids or *hoppers*, as the work-people call them, with the sides graduated in steps (fig. 4), in consequence of the small lines of cubical crystals gradually re-treating inwards. One of these groups, according to Regnault, is thus formed:—Suppose a small cubical crystal to be produced at the surface of the solution, this crystal, from its superior density, tends to sink, but is prevented from doing so by capillary attraction. Around this first crystal other crystals are quickly formed, and become attached to its four upper edges, so as to form a hollow four-sided frame above the first cube; the group descending in the liquid, other crystals form along the upper and outer edges of the first frame, so as to present a second hollow frame; another frame forms on the second; and in this way the group enlarges, chiefly at the surface, since the salt, being equally soluble in hot and cold water, does not tend to deposit crystals on cooling, but only by evaporation, which takes place at the surface alone. The bases and altitudes of these little pyramids are generally equal, thus showing the disposition of the salt to form a cube. The cubes themselves, as obtained by slow evaporation (fig. 5), are well described by Bergmann. He says,—“These cubes exhibit diagonal markings or striæ, but frequently on each side produce squares parallel to the external surface, gradually decreasing inwards; circumstances which show the vestiges of their internal structure, for every cube is composed of six quadrangular hollow pyramids, joined by their apices and external surface: each of these pyramids filled up by others similar, but gradually decreasing, completes the form. By a due degree of evaporation, it is no difficult matter to obtain these pyramids separate and distinct, or six of such, either hollow or more or less solid, joined together round a centre. If we further examine the hollow pyramid of salt, we shall find it to be composed of four triangles, each of which is formed of threads parallel to the base, which threads, upon accurate examination, are found to be nothing more than series of small cubes.”

Fig. 4.

Fig. 5.

The brine is not a pure solution of chloride of sodium, but is contaminated with carbonate of lime and sulphate of lime, which, not being soluble, subside to the bottom of the pan, and form an incrustation, called by the workmen *pan scratch* or *scale*. This gradually accumulates, together with a portion of salt, and becoming thicker from day to day, it is necessary every week, or, where the evaporation is slower, once in three or four weeks, to clear it away by means of sharp iron picks. Heaps of this substance may be seen in the vicinity of the pan-house ready to be mixed with refuse salt, and ground up as *agricultural salt*. The larger fragments are sometimes given to cattle to lick instead of rock-salt. This pan-scratch in appearance resembles a thick layer of opaque ice. According to the analysis of Dr Henry, 480 parts of this substance contained 40 of chloride of sodium, 60 of carbonate of lime, and 380 of sulphate of lime; but the proportions vary in

Salt.

Salt. different brines. The greatest accumulation of pan-scratch is towards the close of the evaporation, for when much salt is deposited in the pan, it forms such a heavy mass at the bottom that the water cannot penetrate it, and the scale or deposit undergoes a kind of calcination and fusion which makes it very hard, and causes it to adhere strongly to the pan.

It was long supposed that the salt of Great Britain was inferior as a preserver of food to the salt produced in France, Spain, and Portugal, by the evaporation of sea-water, and hence we were accustomed to pay large sums of money for an article which we possessed in boundless profusion. Many years ago Dr Henry made a careful inquiry into the subject, in order to ascertain whether this preference of foreign salt was the result of accurate experience or merely prejudice, and in the former case whether any chemical difference could be detected to explain the superiority. The result of this investigation is given in an admirable paper contained in the *Philosophical Transactions*, vol. c.

Dr Henry found that the various descriptions of salt might be divided into *stoved* or *lump salt*, *common salt*, the *large-grained flaky*, and *large-grained* or *fishery salt*. In making the stoved or lump salt, the brine is raised to the temperature of boiling, or 225° F. When the water has nearly all evaporated, the fires are slackened, the salt is drawn to the sides of the pan, and placed in wicker baskets or *barrows* (fig. 6), which are set aside to drain, and afterwards dried in stoves. It loses in drying about one-seventh of its weight. In making this salt, according to Dr Henry's observation, the pan is filled twice in 24 hours, and for common salt only once. In the latter case, the brine is brought to a boiling heat in order to get a state of saturation as quickly as possible, and also to throw down the earthy matters. The fires are then slackened, and the crystallization is carried on at the temperature of from 160° to 170°. The salt is in quadrangular pyramids of close and compact texture. After it is drained in baskets, it is carried to the storehouse, and is not exposed to heat. The large-grained flaky salt is formed at 130° or 140°. It is somewhat harder than common salt, and approaches nearer the natural form of the crystals of chloride of sodium. The pan is filled once in 48 hours. Salt of this grain is sometimes made by slackening the fires between Saturday and Monday, and allowing the crystallization to proceed slowly on Sunday, whence it has obtained the name of *Sunday salt*. For the large-grained or fishery salt, the brine is heated to 100° or 110°, at which temperature the evaporation is comparatively slow, and as there is no agitation produced in the brine, the salt forms in large cubical crystals. Five or six days are required for the process.

Now it is on the difference in size and hardness of the crystals that their adaptability to different uses depends, and not on any differences in chemical composition, for these are too minute to have any influence. The large-grained salt is peculiarly fitted for the packing of fish and other provisions, a purpose to which the small-grained salts are much less suitable. Their different powers of preserving food depend on the size of the crystals and their degrees of hardness. Quickness of solution, other circumstances being equal, is nearly proportional to the quantity of surface exposed; and since the surfaces of cubes are as the squares of their sides, it follows that a salt, the crystals of which are of a given magnitude, will dissolve four times more slowly than one whose cubes are only half

VOL. XIX.

Fig. 6.

the size. The kind of salt, then, which is distinguished for hardness, compactness, and perfection of crystals, will be best suited for packing fish and other provisions, since it will remain permanently between the different layers, or will be very gradually dissolved by the fluids that exude from the provisions, thereby furnishing a slow but constant source of saturated brine; whereas for preparing the pickle or *striking* meat, which is done by immersion in a saturated solution of salt, the small-grained varieties answer equally well; or, on account of their greater solubility, even better. The specific gravity of various samples of salt depending to a great extent on hardness and compactness of crystal, was found to be almost the same in the large-grained British salt as in that of foreign manufacture. Dr Henry remarks that "if no superiority be claimed for British salt, as applicable to economical purposes, on account of the greater degree of chemical purity which unquestionably belongs to it, it may safely, I believe, be asserted that the larger-grained varieties are, as to their mechanical properties, fully equal to the foreign bay salt."

Before proceeding to notice foreign methods of manufacture, we may give the following statistics of salt, derived from the *Mineral Statistics of the Museum of Practical Geology* :—

	Tons.
Cheshire. —	
The quantities of white salt carried on the River Weaver from the 5th April 1857 to 5th April 1858, was	647,437
Do. do. of rock-salt	65,773
Salt carried by railway from the districts of Winsford and Northwich, <i>estimated</i>	525,000
Worcestershire. —	
Stoke and Droitwich	196,500
Ireland. —	
Duncone, near Carrickfergus, belonging to the Belfast Mining Company, shipped	16,660
Do. do. used for manufacturing purposes	5,798
Do. do. white salt manufactured	4,877

Total produce of the United Kingdom ... 1,462,045

The quantities of salt exported from the United Kingdom in the years 1855, 1856, and 1857, with the declared values, were as follows :—

1855.	1856.	1857.
630,154 tons.	745,513 tons.	651,766 tons.
£.268,857	£.276,242	£.239,969

There was formerly a duty on salt, which originated as a war-tax in the ninth year of the reign of William III., and was not removed until the year 1823. The price of salt, in consequence of the duty, was raised from 6d. a bushel to more than 20s.

In countries situated near the sea-coast common salt is frequently obtained by the evaporation of sea-water. There is not more than from 3 to 4 per cent. of saline matter in sea-water, and of this quantity common salt forms nearly two-thirds. Dr Schweitzer found in 1000 grains of the water of the English Channel, near Brighton :—

	Grains.
Water	964.74372
Chloride of sodium	27.05948
Chloride of magnesium	3.66658
Chloride of potassium	0.76552
Bromide of magnesium	0.02929
Sulphate of magnesia	2.29578
Sulphate of lime	1.40662
Carbonate of lime	0.03301

The specific gravity of the water at the surface, and from a depth of 10 fathoms, was 1.0274. A minute quantity of iodine was also found; and Professor George Wilson has discovered fluorine to be an element of sea-water. Dr Forchammer has also detected minute quantities of manganese, ammonia, baryta, strontia, iron, and silica.

In the preparation of salt from sea-water the water is ex-

Salt.

posed in a series of shallow ponds, called *salt-gardens* or *salterns*, to the action of the sun and air. The salterns are laid out on a clay soil on the sea-coast, and are protected from the influence of the tides; they are worked during the warmer months, from March to September. They are arranged in such a way that, as the salt is deposited in the hindermost pools, the foremost ones receive constant supplies of sea-water. In the first place a *collecting pond* A (fig. 7)

Fig. 7.

is filled at the flow of the tide by means of a flood-gate to the depth of from 2 to 6 feet. In this pond the mud and mechanically-suspended substances are deposited, while the clear water is conveyed by means of a pipe to the front pool B, which is divided by a central embankment and arms proceeding alternately from it and the sides of the pool. This pool is horizontal and very shallow, and the salt water moves slowly through it in the direction of the arrows as far as the pipe C, which conveys it into a channel running along the four sides of the saltern. Arriving at the point D, it enters the ponds E into a third series of ponds F, and thence by channels *h* into the crystallizing ponds G. During all this time the brine has become stronger by evaporation of the water, so that when it reaches the crystallizing ponds it is ready to deposit its salt. This is indicated by a reddish tint on the brine. The ponds G are filled from channels at the corners, which admit of being closed with wooden plugs. The salt forms on the surface of the water, and is collected by means of rakes into small heaps *i* at the sides. Here the mother liquor flows off, and is collected in proper channels; and when no more salt separates by crystallization the spent liquor is allowed to flow off through K into the sea. The salt thus collected is contaminated with chloride of magnesium, so that the small heaps *i* are made up into large ones *j*, and covered with straw for keeping off the rain: the moisture of the air liquifies the chloride of magnesium, which gradually becomes separated from the saline mass. The process depends so much on the state of the weather that at the beginning of the season eight days may be required for the deposit of salt; but in fine dry weather salt may be collected two or three times a week, and in very favourable cases every day.

The repeal of the duty on salt enabled the Cheshire manufacturers to sell the article at so low a rate that the proprietors of the salterns could not compete with them. This will readily be understood when it is considered that the price of fuel, strength of brine, and facilities of carriage by river and canal, were all in favour of Cheshire. There was a saltern at Lymington in Hampshire, in which it was the practice to concentrate the sea-water to about one-sixth of its bulk, and complete the operation in boilers. The chief variety of salt manufactured resembled in grain the stoved salt of Cheshire. In preparing it, the salt was

not raked out of the boiler and grained, but the water was entirely evaporated, and the salt taken out every eight hours, and removed into perforated troughs, through which the bittern, or mother-liquor, drained off. Below the troughs, and in a line with the holes, were upright stakes, on which a portion of the salt crystallized, and formed in the course of ten or twelve days on each stake a mass or lump, called a *salt cat*, weighing 60 or 80 lb. During the winter, when the manufacture of salt could not be carried on, sulphate of magnesia (Epsom salts) was manufactured from the bittern.

Salterns can only flourish in countries which have no natural deposits of salt or brine, and where foreign salt is excluded by a high protective duty. The method of evaporating the sea-water differs somewhat in different localities, and attempts have even been made to increase the mineral contents of sea-water before the process of evaporation is commenced. A contrivance of this kind has been in use in Lower Normandy from the ninth century, and it consists in allowing the sea-water to percolate through a filter of sand collected on the sea shore after the tide has gone out, by means of a long broad scoop drawn by a horse. The strength of the sea-water is thus considerably increased, and the evaporation is conducted in leaden boilers with wood fuel, the scum being removed during the boiling. The boiler is repeatedly filled up with sea-water during the evaporation, and the salt which forms is kept in motion by means of long rakes, to prevent the lead from fusing. When the whole of the water has been driven off it is removed by means of a perforated tool (fig. 8), and

Fig. 8.

placed in baskets suspended over the boilers, the steam from which in the next charge penetrates the baskets, and removes much of the bitter deliquescent salts. The salt is next taken to warehouses, and by means of the tool (fig. 9)

Fig. 9.

is piled up on the floor, which is made of hard cement. The salt remains here for about two months, during which time it loses from 20 to 23 per cent. of bittern. The salt is now fine and pure, and quite white. According to Dumas, from 700 to 800 litres of salt water are required to produce from 150 to 225 kilogrammes of salt. According to Sir Stamford Raffles a method of obtaining salt similar in principle to the above is adopted on the south coast of the island of Java.

There are vast deposits of rock salt at Bochnia and Wieliczka in Galicia, and others equally important along each side of the great Carpathian range, extending at various intervals from Moldavia to Suabia. In this extensive tract are the celebrated salt-mines of Wallachia, Transylvania, Galicia, Upper Hungary, Upper Austria, Styria, Salzburg, and the Tyrol. In some cases culinary salt is prepared from brine, formed by letting down fresh water through a bore to the middle of a salt-bed, and pumping it up as a saturated solution, which may be treated in the manner already described for the Droitwich works. In some inland districts which are not so fortunate as to possess deposits of salt, and where land carriage and fiscal regulations render the imported article costly, advantage is taken of natural salt-wells where such occur. These are for the most part but slightly impregnated with salt, arising probably from their contact with fresh water after leaving the salt-

Salt.

Salt.

bed. Some of these springs have only half the strength of sea-water, and yet by judicious arrangements it has been found profitable to work them. The method of evaporation by artificial heat is of course out of the question, even supposing fuel to be abundant, which it is not. We will first describe the method which has been in use, it is said, from the year 1550 at Moutiers, the capital of the province of Tarentaise in Sardinia, taking as our chief authority Mr Bakewell's *Travels in the Tarentaise*, published in 1823.

The method here adopted is based upon the physical fact, that the rate of evaporation depends, other things being equal, on the amount of surface exposed; and the method practically consists in raising the weak brine to a height, and allowing it to fall in the form of rain, the single drops being retarded in their fall by a peculiar contrivance. In this way 3,000,000 lb. of salt are produced every year, from a source which in most other countries would scarcely be noticed except for medicinal purposes. The salt-springs rise at the base of a limestone rock, and are passed along an open canal, through the distance of about a mile, to the salt-works. In this canal the brine deposits a red ochreous incrustation, and also gives off a mixture of carbonic acid and sulphuretted hydrogen. The water has an acidulous and slightly saline taste: its temperature at its rising is 99° F., and it contains only 1.83 per cent. of saline matter, other springs only 1.50. In addition to common salt, the water contains small proportions of sulphate of lime, sulphate of soda, sulphate and muriate of magnesia, and oxide of iron. Thus there is about 1½ lb. of common salt in 13 gallons of water. The first method of evaporating the water was by allowing it to trickle repeatedly through pyramids of rye-straw arranged in open galleries. A portion of the sulphate of lime was deposited on the straw, and the water attained a certain degree of concentration. The process was then completed at a salt-pan with fuel. This plan continued in operation for nearly two centuries. In 1730 the modern plan came into use. There are four evaporating houses, called *maison d'épaves* or "thorn-houses," the first two of which are 350 yards long, about 25 feet high, and 7 feet wide. They consist of frameworks of wood supported on stone buttresses, and containing double rows of fagots of black thorn, placed loosely so as to admit the air, but supported firmly by transverse pieces of wood. In the centre of each house is a stone building containing the pumping apparatus, moved by a water-wheel. By this means the water is raised to the top of the thorn-house, and is received in channels on each side, extending the whole length: these long channels distribute it to smaller ones, from which it trickles through a multitude of small holes in a very gentle shower upon the fagots, where it is further divided into innumerable drops, falling from one point to another, and is received in troughs below, from which it is again pumped up, until by repeated exposure to the air it is deemed sufficiently concentrated to be passed to the evaporating house No. 2, where it undergoes similar treatment. These thorn-houses are placed at different angles, so as to catch the different currents of air that flow down the valley. The sulphate of lime is deposited in incrustations on the twigs. The thorn-house No. 3 is covered to preserve the salt water from the rain: it is 370 yards in length, and has 12 pumps on each side to distribute the water more equally. After passing through No. 3, the water, reduced to one-seventh of its original bulk, is conveyed along channels to the thorn-house No. 4, which is 70 yards in length, where it is concentrated to saturation. The time occupied in obtaining this result, from the first commencement, is in summer about one month; in wet seasons of course much longer. A good idea will be formed of the quantity of water evaporated by the following statements:—8000 hogsheads, when received at the thorn-houses Nos. 1 and 2, contain about 1½ per cent. of salt, and

are reduced by evaporation to 4000 hogsheads; 4000 hogsheads, when received at No. 3, contain about 3 per cent. of salt, and are reduced to 1000 hogsheads; 1000 hogsheads, when received at No. 4, contain about 12 per cent. of salt, and are reduced to 550 hogsheads; 550 hogsheads received at the pans contain nearly 22 per cent. of salt. The process is completed in the usual way, and it is calculated that only 1/16th part of the fuel is consumed that would be required for evaporating the whole of the water by fire. The fagots last from four to seven years, those in Nos. 1 and 2 decaying sooner than those in Nos. 3 and 4. The chief deposit of sulphate of lime is in No. 3. Sulphate of soda is also manufactured at the works, and the other alkaline refuse goes to the glass-maker.

The method of graduation invented at Moutiers was introduced into Saxony in 1559, and has received considerable attention on the part of modern chemists. In Knapp's *Technology* (translated by Ronalds) is an engraving of a portion of one of the evaporating houses which we here copy (fig. 10.) The weak brine is pumped up into a large

Fig. 10.

reservoir, from which it flows into the troughs *b, b* of the thorn-house. From these troughs the brine is conveyed in a thin stream to a perforated channel *c*, from which it falls in drops on the wall of black-thorn fagots *t*. There is a sloping board placed so as to prevent the wind from giving a wrong direction to the drops, and the whole arrangement is protected from the weather by a roof *r*, a portion of which has been removed in our engraving to show the troughs. The building is erected in an airy place, in a direction at right angles to that of the prevailing wind; but should the wind blow slantingly upon one of the faces of the wall, so as to dissipate the brine, certain channels are closed by means of a lever, and others are opened, whereby the supply of brine is carried to the opposite side of the wall. At Schönebeck the thorn wall exposes a surface of 390,000 square feet, and this evaporates on an average 3 7/10ths cubic feet of water from each square foot of wall per day, or nearly a million and a quarter hogsheads of water in a year of 258 working days, which include the most favourable portion of the year, frost being found to be injurious, for below 27° Fahr. sulphate of magnesia, and a portion of chloride of sodium, become converted into chloride of magnesium and sulphate of soda, and this decomposition, once begun, is not reversed when the weather becomes warmer; so that not only is salt lost, but the quantity of chloride of magnesium, which is injurious in the boiling process, is increased. Some loss is also entailed by the evaporation of salt with the water, an observation made in 1770 by Pallas, in the neighbourhood of the salt lakes of Asiatic Russia, where he found the dew to have a decidedly salt taste. The deposit upon the thorns, known as *thorn-stone*, consists of the carbonates of lime, magnesia, manganese, and iron, with traces of chlo-

Salt.

Salt.

rides. These deposits gradually fill up the interstices of the thorn wall, and stop the draught; so that it is necessary to renew the wall every five, six, or eight years. In the brine cisterns the deposit forms a fine mud, with a greyish kind of scum filled with bubbles; this consists chiefly of living infusoria, evolving pure oxygen. The brine is generally considered fit for boiling when it contains 23 per cent. of salt. If the natural spring contain as much as this, it is boiled down at once without being graduated.

After the brine has been graduated it is passed into vast reservoirs of masonry covered over and protected from the frost. Here the brine makes a further deposit of suspended matters. The boiling is carried on in winter only, in flat four-sided pans of sheet-iron, somewhat deepened towards the middle. The bottom of each pan is supported by brick-work (fig. 11), which contains the flues for distri-

Fig. 11.

buting the fires and heating the drying-chambers. The pan is covered with a roof-shaped hooding of boards, with a steam or vapour trunk *s*, furnished at the bottom with wooden shutters *d*, which can be turned back so as to allow free circulation of air over the surface of the brine. The vapour is said to contain about 1 per cent. of salt, so that means are taken for condensing it, or rather that portion of it which trickles down the sides of the chimney, at the bottom of which is fixed a sort of channel connected with a tube *t*, leading into a tank. The process of boiling consists of *first*, the *schlotage*, or the further purification and evaporation of the brine, up to the point of saturation; and *secondly*, the *soccage*, or crystallization of the salt. During the boiling the scum which rises to the surface is removed, while the other impurities form pan-scale. A pan containing 1600 feet of brine, or 176 cwt. of salt, is re-filled as often as one-fourth of the quantity is evaporated; so that when, after twenty or twenty-four hours, a pellicle of crystals begins to form on the surface the fire is slackened until the temperature of the brine falls to 194° Fahr., and from that to 167°, when with slow evaporation the *soccage* begins, and is continued for several days. In this way salt of coarse grain is produced. During the *soccage* the salt is raked to the edge of the pan and placed in baskets of peeled willow, or heaped upon boards to drain, after which it is dried and packed for sale. The salt thus formed is not quite pure; it usually contains a minute portion of one or other of the following salts:—Chloride of magnesium, chloride of calcium, sulphate of soda, sulphate of magnesia, and sulphate of lime. The chloride of magnesium has the greatest influence on the quantity of the salt, on account of its highly saline taste and deliquescence in the air. Pure chloride of sodium does not attract moisture, but if it contain only a minute portion of chloride of magnesium, it becomes wet in damp weather. The greater pungency, however, of this salt, causes it to be preferred in places where salt is costly, as a smaller quantity of it will suffice. The chloride of magnesium can be removed during the *soccage* by the addition of slaked lime to the brine.

Salt
||
Salt Lake.

It is remarkable that in the neighbourhood of these inland salt-works plants which usually grow on the sea-shore are met with,—such as the *Salicornia*, the *Salsola kali*, the *Aster tripolium*, the *Glaux maritima*, &c.,—because in such situations they find food adapted to their habits. Liebig supposes that the seeds of these plants must have been carried by the wind or by birds, and scattered over the several hundred miles which separate the salt-works from the sea, but that they only germinated in those places where they found the conditions essential to their existence. Small fishes (*Gasterostens aculeatus*) are found in the salt reservoirs at Nidda in Hesse-Darmstadt.

There is yet another method of procuring salt, based upon the remarkable property of ice to exclude foreign substances from its composition, so that when brine is exposed to a low temperature it resolves itself into two portions,—one consisting of pure water, which crystallizes or freezes, and can be removed in the form of ice; the other portion or brine remaining liquid, and becoming intensely salt by the removal of the fresh water. The salt can be separated by the usual method of boiling. The product, however, is very impure, since the effect of low temperature, as already noticed, is to convert the sulphate of magnesia of the brine into sulphate of soda and chloride of magnesium at the expense of the salt. A portion of the brine formed in this way from the water of the sea of Okhotsk was found by Hess to contain—

Common salt	77.60
Sulphate of soda.....	13.60
Chloride of aluminum	6.20
Chloride of calcium	0.94
Chloride of magnesium	1.66

100.00

In places where the salt prepared from such brine is used, the people are subject to scorbutic diseases, which Hess attributes to the presence of these chlorides. Such brines should therefore in all cases be purified by means of lime. It is remarked by Dumas that this is the first analysis of bay salt in which chloride of aluminum occurs. (C. T.)

SALTA. See PLATA, *La*.

SALTASH, a market-town of England, in the county of Cornwall, 3½ miles N.W. of Davenport. The houses rise tier above tier on the steep bank of the Tamar, and present striking and picturesque contrasts; some being of brick, some of stone, some fronted with plaster, others with slates. There is a town-hall, an old church, and a grammar school. Most of the inhabitants are fishermen. Saltash was formerly a parliamentary burgh, returning two members, but was disfranchised by the Reform Act of 1832. Pop. 1621.

SALT COATS, a seaport-town of Scotland, in the county of Ayr, 24 miles S.W. of Glasgow. It is built on the shore of the Bay of Ayr, and has some good houses, but it is in general a mean-looking place. There is a town-hall with an elegant spire, an Established church, a Free church, two belonging to the United Presbyterians, and one to the Roman Catholics. The inhabitants are supported chiefly by the weaving and sewing of muslin for the Glasgow market. Salt is manufactured, and at either end of the town there are large chemical works. Ship-building, which formerly formed an important branch of the industry of the place, has of late years much declined. Large quantities of coals are exported to Ireland. The harbour however is not good, and inferior to that of Ardrossan. Pop. 4338.

SALT LAKE, CITY OF THE GREAT, in the United States of North America, capital of the territory of Utah, in a beautiful and richly-cultivated plain, bounded on the E. by a range of snowy mountains bearing the name of Wahsatchan, and on the W. by the Jordan River, on the right bank of which the city stands, about 22 miles S. of the Great Salt Lake, and 4350 feet above the level of the

Saltillo
||
Salvage.

sea; N. Lat. 40. 46., W. Long. 112. 6. It is laid out on a very regular and systematic plan, divided into 260 squares by streets, 130 feet broad, crossing each other at right angles. Each of these squares is 10 acres in extent, and occupied by eight houses standing 20 feet back from the street, and surrounded with extensive grounds planted with trees and shrubbery. The houses are built of bricks dried in the sun, and have in general only one storey. A perennial stream of water flows through the town, and is carried by channels to each house and garden. Of the public buildings the most important will be the great temple, the foundations of which have been laid, and to the construction of which each of the saints has to contribute his tithe in money and labour. In the large square where it stands are the house of the president or high priest, and other public buildings. The city has also a fine theatre, which cost more than L.4000. Salt Lake City was laid out in 1847 by a company of 143 Mormonites. (See MORMONISM and UTAH.) Pop. (1853) estimated at 10,000.

SALTILLO. See MEXICO.

SALTPETRE, NITRE, or nitrate of potash, a compound of nitric acid and potash. It is generally obtained in the form of six-sided prismatic crystals, terminated by six-sided pyramids, joined by their bases. Its specific gravity is 1.933. (See CHEMISTRY.) It is used in the various arts, and is the principal ingredient in the manufacture of gunpowder. (See GUNPOWDER.)

SALUZZO, a town of Sardinia, Piedmont, capital of a province of the same name, in the division of Coni, at the foot of a branch of the Alps, which separates the valley of the Po from that of the Vraita, 31 miles S. by W. of Turin. It is a large cathedral town, consisting of two parts, an upper and a lower; the former, anciently fortified, has steep streets and many good houses, though it is somewhat more ancient than the widely-extended lower town. The cathedral in one of the suburbs is surmounted by a tall, elegant tower; two of the other churches are more remarkable for their monuments than for their architectural beauty, and there are several convents in the town. The ancient castle, once the residence of the marquises of Saluzzo, is now used as a prison. There are also an old town-house, a college and several schools, a theatre, and other buildings. Iron-ware, jewellery, hats, leather, and silk are manufactured here; and there is a considerable trade in cattle, corn, and wine. Chestnuts are grown in large quantities in the vicinity. Saluzzo was once the capital of a marquisate, which was for a long time in the possession of France. Pop. about 15,000. The province, which has an area of 511 square miles, is occupied in its western part by the Alps, the chief summit here being Monte Viso; and is watered by the Po and its affluents the Maira and Vraita. The soil being fertile, and the climate good, abundance of corn, wine, fruit, hemp, and silk is produced. Iron, copper, marble, and slate are the chief minerals obtained here. Pop. 160,608.

SALVADOR, ST. See SAN SALVADOR.

SALVAGE, an allowance made to those persons, other than the crew, by whom ships or goods have been saved from the sea, fire, pirates, or enemies. 1. In fixing the rate of salvage upon losses by perils at sea, regard is usually had, not only to the labour and peril incurred by the salvors, but also to the degree of relationship to the property saved, the anxiety manifested by them, the value of the ship and cargo, and the danger from which they were rescued. Sometimes a *half*, sometimes a *tenth* of the property saved has gone to the salvors. 2. During a time of war, when British war-ships re-capture British merchantmen from the enemy, they are allowed a salvage of one-eighth part of the re-captured ships and cargoes (stat. 43 Geo. III., c. 160), and one-sixth part of their value on ships re-captured by privateers. An act of her Majesty's government (16 and

17 Vict., c. 131) lays down several regulations regarding the prosecution of such claims. (For further information regarding salvage, see the works of Abbot, and of Maude and Pollock, *On the Law of Shipping*; and M'Culloch's *Commercial Dictionary*.)

SALVANDY, NARCISSE ACHILLE, *Comte de*, a French writer and statesman, sprung from an Irish family, was born at Condom, in the department of Gers, on the 11th of June 1795. Having been sent at a very early age to Paris, he received his education at the Lycée Napoléon. The needy youth enrolled himself in a volunteer corps in 1812, and served with much distinction throughout the campaigns of 1813-14, and had the honour to receive the decoration of the Legion of Honour from the hands of the emperor on the 6th of April 1814. On the restoration of the Bourbons, Salvandy expressed his devotedness to the new regime in these words:—"After having shed my blood in an illegitimate cause," he wrote to the Duc d'Angoulême, "I would die for the Bourbons." Having accompanied Louis XVIII. to the Belgian frontier in 1815, he returned to Paris, and published his pamphlets, *Mémoire sur les Grièfs et les Vœux de la France*; and *Observations sur le Champ de Mai*. Next year he brought out *La Coalition et la France*, which produced a considerable sensation in the courts of Europe. In 1819 he was made a member of the Council of State, and appointed Maître des Requêtes; but the French cabinet not acting according to his liking in the electoral system, he had the audacity, at the risk of place, to defend that system in his clever brochures *Vues Politiques* and *Dangers de la Situation présente*. In 1820, Salvandy having gone to Spain during the ministry of the Duc de Richelieu, studied with warm interest the liberal movement in that country. In 1823 appeared his celebrated romance *Don Alonzo, ou l'Espagne*, which has been frequently reprinted. In 1824 began his connection with the *Journal des Débats*, which was destined to continue at intervals for the next twenty years. In his political articles he pursued a bold yet steady course, scorning to fawn upon any potentate, and flattering no party. He never abandoned his fundamental principle, that there was no security for France but in constitutional monarchy—a maxim which he urged with all the warmth of language and energy of style competent to a man of a lively imagination and of perfect self-consciousness. Salvandy held the position of councillor of state during the ministry of Martignac, but resigned on the subsequent dissolution of the cabinet. During the reign of Louis Philippe, he continued to pursue his liberal policy, both in political leader and in pamphlet, with the same steady adherence which had hitherto characterised him. He held several offices of state, was made a member of the French Academy, and was created a count. On the *coup d'état* of December 1851, he went into retirement, and died on the 15th December 1856, in his sixty-second year.

SALWEEN, or SALUEN, a large river of Further India, rises on the eastern frontiers of Tibet, and flows southwards, forming, for a great part of its course, the eastern boundary of Burmah, and then entering the British dominions, and separating Pegu from the Tenasserim provinces. It falls into the Gulf of Mastaban by a broad mouth, between the towns of Moulmein and Mastaban. The whole length is estimated at 600 miles; and though the river has been very little explored, it is believed to flow through a fertile, well-wooded country, and to be navigable for a considerable distance from the sea.

SALZBURG, DUCHY OF, a crown-land of the Austrian empire, bounded on the N. and N.E. by Upper Austria, E. by Upper Austria and Styria, S. by Carinthia and the Tyrol, and W. by the Tyrol and Bavaria; area, 2757 square miles. It is almost entirely mountainous, being occupied by that chain of the Alps called the Salzburg

Salvandy
||
Salzburg.

Salzburg. Alps or the Tauern. These extend along the southern frontier, and send off many branches, forming glens and valleys of exquisite romantic beauty. The principal summits are the Wiesbach or Krummhorn, 11,297 feet high; and the Kitzsteinhorn, 10,106 feet. The Salzach rises on the borders of Tyrol, and flows at first eastwards down the romantic valley called Pinzgau; then turns suddenly to the north, and traversing the equally fine valley called by its name, leaves Salzburg to join the Inn on the frontiers of Bavaria and Upper Austria. Almost all the rivers of the country discharge their waters into this, which is by far the most important. There are a number of lakes and many exceedingly beautiful waterfalls in Salzburg. Notwithstanding the mountainous nature of the surface, the valleys are in general very fertile, and a large proportion of the soil is productive. Corn is raised in considerable quantities, and excellent vegetables may be grown in sheltered spots; but it is the rearing of cattle that forms the chief support of the inhabitants. Of minerals, gold, silver, copper, lead, iron, manganese, and arsenic are obtained; salt, too, is extensively worked, especially in the great salt-works at Hallein. In many places there are mineral springs. The manufacturing industry of the country is, on the whole, not very highly developed. The present duchy of Salzburg was formerly an archbishopric, immediately dependent on the German empire. Christianity was introduced here among the heathen inhabitants by a Scotchman named Rupert, afterwards canonized, who found the land nearly a desert, and became the first bishop of Salzburg in 716. The see was afterwards raised to the rank of an archbishopric, and its occupant became primate of Germany, and was the only archbishop, besides the spiritual electors, who had a seat and voice in the diet. The privileges of these prelates were numerous; their temporal possessions gradually became extensive, and their revenues enormous. The Reformed doctrines early found admission into Salzburg, but the utmost severity was used to suppress them, until at last, in 1732, the Protestant states obtained leave for their fellow Protestants to leave the country, on which more than 30,000 departed, and settled in Prussia, Würtemberg, and in the North American colony of Georgia. In 1801 the see was secularized, and given to the ex-Duke of Tuscany, with the title of Elector; but by the peace of Pressburg in 1806, it was annexed to Austria. From 1809 to 1815 Salzburg belonged to Bavaria; but in the latter year, with the exception of a small portion, it was restored to Austria. The inhabitants are almost all Germans, and of the Roman Catholic religion. Pop. (1854) 154,379.

SALZBURG, the capital of the above duchy, on both sides of the Salzach or Salza, just at the entrance of the hill country, where the river issues from its confined valley into the Bavarian plain, 156 miles W.S.W. of Vienna. Few German towns can rival this in the beauty of its situation: the stream, with grayish-white water, telling of distant glaciers, flows among meadows and waving corn-fields, between two castle-crowned cliffs, at the foot of which clusters the Italian-like town, with its flat roofs, numerous churches, and marble edifices; while in the background rise the slopes of hills darkly clothed in wood, and the scene is closed in by the snowy line of loftier mountains in the remote distance. The part of the town that lies to the left of the river is almost inclosed by the Castle Hill (*Schloss-berg*) and the Monk's Hill (*Monch-berg*); while a bridge 370 feet long leads to the other portion, on the slope of the Capuchin Hill (*Capuziner-berg*). On the summits of the two latter hills there are extensive plateaus, laid out in fine walks, and planted with trees. The ancient castle on the hill, to which it gives its name, has been long dismantled, and is now only used for barracks. Its towers rise 400 feet above the square below. Besides the natural strength of its position, Salzburg is defended by fortifications, and en-

tered by eight gates. One of the latter, called the New Gate, is formed by a tunnel cut through the Monk's Hill, constructed by Archbishop Sigismund in 1767. The cathedral is a large and splendid marble edifice in the Italian style, built in the seventeenth century. Near it is the former archbishop's palace, now occupied by public offices. In the square in front stands a beautiful marble fountain and a statue of Mozart, who was born here in a house that is still to be seen marked with an inscription. Among the many churches of the town, that of St Peter is remarkable for its monuments, and for a curious old churchyard attached to it. There are numerous convents, one of which, the Benedictine, is among the oldest in Germany, and has a fine library. The lyceum, formerly a university, has also a library of 36,000 volumes and 300 MSS. There are other schools, a theatre, several hospitals, &c., in the town. The manufactures comprise leather, iron wire, and pottery; the trade is considerable; and two annual markets are held. Salzburg is still the seat of an archbishop; also of the provincial government and courts of law. Pop. (1851), exclusive of the military, 17,009.

SAMAKOV, a town of European Turkey, Bulgaria, at the foot of the north slope of the Balkan hills, in the Sanjak, and 30 miles S.E. of Sophia. It is defended by an embattled wall, flanked with towers; and has manufactories of heavy iron goods, the materials for which are obtained from the mines in the vicinity. Pop. 5000.

SAMAR, one of the Philippine Islands, lying to the S.E. of Luzon, separated from it by a strait 20 miles wide, between N. Lat. 11. and 12. 48., E. Long. 24. 25. and 25. 55. Its form is triangular, with the apex pointing southwards: length, 150 miles, greatest breadth, 80; area, 5470 square miles. The northern position is occupied by rugged, lofty mountains; while the whole is densely wooded, and watered by numerous rivers, large and small. The climate is healthy, the soil moderately fertile, and the productions numerous, including many useful and valuable woods, palm oil, cocoa, rice, Manilla hemp, &c. Samar is inhabited by a mixed race, the offspring of Spaniards by Indian mothers; they manufacture mats and other articles, and carry on some trade. The island belongs to Spain; and the capital is Cabalunger, on the west coast. Pop. 99,635.

SAMARA, a government of European Russia, bounded on the N. by that of Kasan, E. by Orenburg and the Kirgheez territory, S. by Astrakhan, and W. by Saratov and Simbirsk; area, 51,588 square miles. It consists of a broad, open, slightly undulating plain, lying between the rivers Volga and Ural,—the former of which bounds the government on the west, and the latter on the east. By these rivers and their affluents, especially those of the Volga, the country is watered. The government was formed by an ukase in December 1850, from portions of those of Orenburg, Saratov, and Simbirsk, in the following proportions:—

	Sq. Miles	Pop. (1846).
From Orenburg, 3 districts . . .	21,393	514,014
„ Saratov, parts of 2 districts..	20,102	327,831
„ Simbirsk, 2 districts	10,093	274,118
Total... ..	51,588	1,115,963

Thus, in the statistics given of these governments for 1849, those parts are included which now belong to Samara, as the new government had not then been formed. The great majority of the inhabitants belong to the Greek Church; but there were also, in 1851, 122,113 Mohammedans, 48,583 Protestants, 32,140 Roman Catholics, 3426 pagans, and a few Jews. The government is divided into seven circles, as follows:—

	Pop. (1851).		Pop. (1851).
Samara	146,293	Bugulma	146,880
Stavropol.....	163,534	Busuluk.....	257,510
Nicolaievsk	250,585		
Novyi Usen.....	133,984	Total.....	1,320,108
Buguruslan.....	221,322		

Samakov

Samara
||
Samaritans

SAMARA, the capital of the above government, at the confluence of the river of the same name with the Volga, 550 miles E.S.E. of Moscow. It was originally built in 1591 as a defence against the incursions of the Bashkirs and the Kalmucks, and for that purpose was surrounded by an earthen wall and a deep moat. These fortifications were destroyed in 1703, and a citadel built in their stead, but of this only a few vestiges are now to be seen. The town contains two cathedrals and three other churches, a gymnasium and various other schools, several charitable institutions, cloth and silk factories, &c. Near the confluence of the rivers is a double row of warehouses built of pine wood, and supported by tarred pillars. These, as well as others in different parts of the town, are used in connection with the great fairs held here twice a year,—one in the second week of Lent, and the other on the 14th (26th) September. Each of the warehouses can contain from 25,000 to 30,000 cwt. of corn. For a long time Samara has been one of the principal markets for corn on the Volga; and in 1852 there were sold here 631,412 quarters of wheat, and 16,613 of lintseed. The value of goods brought to the first fair is generally about L.41,000, of which L.13,000 worth are sold; that of those brought to the second about L.66,000, of which L.20,000 worth are sold. Pop. 24,405.

SAMARANG, a seaport of Java, capital of a Dutch province, at the mouth of a river of the same name, on the north coast of the island, 240 E.S.E. of Batavia. It is pretty well built, and encircled with a wall and moat, sufficiently strong to resist any attacks of the natives. The river forms a harbour, which is rather shallow; but about 2 miles off there is a roadstead commanded by a fort. There are here a Protestant and a Roman Catholic church, several mosques, a school, observatory, theatre, court-house, town-hall, &c. Leather and cotton fabrics are manufactured, and an active trade with the interior is carried on, coffee, pepper, and rice being exported. Pop. about 50,000.

SAMARCAND, a fortified city of Turkestan, in the kingdom and 100 miles east of Bokhara, in the midst of a country exceedingly beautiful and fertile, on the Soyd or Zer Afshan, once the splendid seat of the triumphs of Tamerlane, and inhabited then by 150,000 people. It is now in a very decayed condition, and many of its former streets are covered with ruins, or occupied by fields, gardens, or groves. The most conspicuous and interesting building is the mausoleum of Tamerlane and his family, a magnificently-ornamented octagonal building, surmounted by a dome. In the citadel stands the palace of the Emir or Khan of Bokhara. Under Tamerlane, Samarcand was a great seat of Mohammedan learning, and contained no less than forty medressas or colleges; but of these, three only remain,—square buildings with porcelain mosaic on the walls and minarets at the corners. Of the numerous mosques, too, many are quite in ruins. The only important modern buildings are the bazaar and caravansaries. Manufactures of cotton and silk cloth, silk paper, and other articles are carried on. The trade of the place has much declined, having been nearly all transferred to Bokhara, and comparatively little business is now done except when the caravans from various quarters visit the town. Pop. about 10,000.

SAMARIA. See PALESTINE.

SAMARITANS. In the books of Kings there are brief notices of the origin of the people called Samaritans. The ten tribes which revolted from Rehoboam, son of Solomon, chose Jeroboam for their king. After his elevation to the throne he set up golden calves at Dan and Bethel, lest repeated visits of his subjects to Jerusalem, for the purpose of worshipping the true God, should withdraw their allegiance from himself. Afterwards Samaria, built by Omri, became the metropolis of Israel, and thus the

Samarrah.

separation between Judah and Israel was rendered complete. The people took the name *Samaritans* from the capital city. In the ninth year of Hosea, Samaria was taken by the Assyrians under Shalmaneser, who carried away the inhabitants into captivity, and introduced colonies into their place. The dregs of the populace, particularly those who appeared incapable of active service, were not taken away by the victors. With them, therefore, the heathen colonists became incorporated. But the latter were far more numerous than the former, and had all power in their own hands. The remnant of the Israelites was so inconsiderable and insignificant as not to affect, to any important extent, the opinions of the new inhabitants. As the people were a *mixed* race, their religion also assumed a *mixed* character. In it the worship of idols was associated with that of the true God. But apostasy from Jehovah was not universal. On the return of the Jews from the Babylonish captivity, the Samaritans wished to join them in rebuilding the Temple, saying, "Let us build with you; for we seek your God, as ye do; and we do sacrifice unto him since the days of Esarhaddon, king of Assur, which brought us up hither" (Ezra iv. 2). But the Jews declined the proffered assistance; and from this time the Samaritans threw every obstacle in their way. Hence arose that inveterate enmity between the two nations which afterwards increased to such a height as to become proverbial. In the reign of Darius Nothus, Manasses, son of the Jewish high-priest, married the daughter of Sanballat the Samaritan governor; and to avoid the necessity of repudiating her, as the law of Moses required, went over to the Samaritans, and became high-priest in the temple which his father-in-law built for him on Mount Gerizim. From this time Samaria became a refuge for all malcontent Jews; and the very name of each people became odious to the other. About the year B.C. 109 John Hyrcanus, high-priest of the Jews, destroyed the city and temple of the Samaritans; but Herod rebuilt them at great expense B.C. 25. In their new temple, however, the Samaritans could not be induced to offer sacrifices, but still continued to worship on Gerizim. At the present day they have dwindled down to a few families. Shechem, now called Nablus, is their place of abode. They still possess a copy of the Mosaic law.

A different account of the origin of this people has been given by Hengstenberg, whom Havernick and Robinson follow. It has been ably combated by Kalkar (in *Pelt's Mittheilungen* for 1840, *drittes Heft*, p. 24, &c.), to whom the reader is referred.

With the remnant above referred to, a correspondence was formerly maintained by several learned Europeans, but without leading to any important result. It was commenced by Joseph Scalger in 1559; and resumed, after a century, by several learned men in England in 1675, and by the great Ethiopic scholar, Job Ludolf, in 1684. The illustrious orientalist De Sacy also held correspondence with them. All their letters to England and France, and all that was then known respecting them, he published in a work entitled, "*Correspondance des Samaritains*," &c., in *Notices et Extr. des MSS. de la Bibloth. du Roi*, tom. xii. The best accounts of them given by modern travellers are by Pliny Fisk (*American Missionary Herald* for 1824), who visited them in 1823; and by Robinson and Smith, who visited them in 1838 (see *Biblical Researches and Travels in Palestine*, iii. 113–116).

SAMARRAH, a town of Asiatic Turkey, on a cliff forming the left bank of the Tigris, in the pashalic and 65 miles N.N.W. of Bagdad. It is a miserable place, encircled by a wall, and only remarkable for two beautiful monuments to Moslem saints, both surmounted by domes, one of which, once covered with gold, is now quite white; while the other is beautifully enamelled with white and yellow flowers on a bluish ground. These attract pilgrims

Sambas
||
Samos.

from all parts of Persia, to the number of 10,000 yearly; but the resident population does not exceed 1000.

SAMBAS, a town of Borneo, capital of a Mohammedan state of the same name, on the River Sambas, about 30 miles from its mouth, on the west coast of the island, 72 miles north of Pontianak. It lies in a low, swampy country, and the houses are generally raised on piles. There is here the residence of a native sultan, tributary to the Dutch, and of a Dutch resident. Pop. 9400. The country is fertile and populous, and contains the richest gold mines in Borneo. These are worked by Chinese. The River Sambas flows generally west, and after a course of 100 miles, falls into the Indian Ocean. It is navigable for boats as far as Sambas, and has auriferous sands.

SAMBOR, a town of the Austrian empire, capital of a circle of the same name in Galicia, on the left bank of the Dniester, 46 miles S.W. of Lemberg. It contains an ancient Bernardine convent, a gymnasium and normal school, courts of justice, &c. Linen cloth is manufactured here; and an active trade is carried on. Pop. 10,682.

SAMNIUM, one of the principal districts of ancient Central Italy. The name was sometimes used in a more extensive, sometimes in a more restricted sense. In the more usual sense of the term, Samnium was an inland district, bounded on the N. by the Mursi, Peligni, and Fren-tani, E. by Apulia, S. by Lucania, S.W. and W. by Campanium and Latium. The Samnites were a people of Sabine origin, who migrated into this country at a comparatively late period. The date either of their earlier or later migration is unknown. They became finally swallowed up by the Roman people, after having engaged in a long series of desperate struggles known as the Samnite Wars. (See ROMAN HISTORY.)

SAMOS, an island of the Grecian Archipelago, lying off the coast of Asia Minor, from which it is separated by the strait of Little Boghaz, where narrowest, not more than a mile wide. The Great Boghaz, which is about 10 miles in width, separates the other extremity of the island from Icaria. Samos is about 27 miles in length from E. to W., by about 12 in extreme breadth; and is between 37.35 and 37.48 N. Lat., and 26.36 and 27.8 E. Long. It is elevated and mountainous, being traversed by two lofty ranges of mountains stretching from E. to W.; but there are also many valleys of considerable size, especially towards the south. The highest summit, called Kerkis, the ancient Cercetius Mons, reaches the height of 4725 feet, and is covered with perpetual snow. The mountains are in some places steep and barren; but for the most part they are at present, as in the times of antiquity, covered with forests of oaks and pines, with vineyards, and with olive-grounds. A few small rivers water the island, and some traces have been discovered of artificial irrigation. The rocks consist mainly of white marble, which is the principal mineral production. Iron, lead, and silver are also obtained. In the valleys the soil is very rich, and the scenery beautiful. Celebrated in ancient times for its great fertility, Samos is still one of the most productive islands of the Archipelago, though it has not now the advantage of that careful system of cultivation which made use of all the available ground by means of terraces along the mountain-sides. Corn, wine, oil, figs, cotton, and silk are the principal articles of export. The Samian wine, which is now much esteemed, did not enjoy a favourable reputation in the ancient world. The chief town in the island is Chora or Khora, which stands near the site of Samos, the ancient capital, and has a population of 1000. It is defended by a castle, and has a good harbour. There are other small ports on different parts of the coast. Samos now belongs to the Turkish empire; but has enjoyed since 1835 a position of virtual independence, governed by a Greek with the title of "Prince of Samos," and paying a fixed annual tribute to

Samo-
thrace.

the Porte. In the earliest times the island bore several names besides the one which it ultimately retained, and which was given to it most probably on account of its elevated character. The original inhabitants are said to have been Carians and Leleges; but at the time of the Ionian emigration to Asia, Greek settlers established themselves, and Samos became an important member of the Ionian league. It was chiefly distinguished for commercial and maritime enterprise: its ships exhibited the earliest improvements in naval architecture; and one of its citizens was the first who passed the pillars of Hercules, and visited Tartessus. Several colonies were founded by Samos on the shores of the Ægean and the Propontis. During the short but prosperous reign of Polycrates (B.C. 532-522), the Samian navy was the most powerful in Greece; and the island maintained its independence of the Persian empire, being in alliance at first with Amasis of Egypt, and afterwards with his enemy Cambyses of Persia. The capital was at that time one of the finest cities in the world, and was encircled by many public works and buildings constructed by the monarch. He resided in a fortified palace; there was a large Ionic temple of Juno by a native architect, a harbour inclosed by two artificial moles, and a tunnel hewn out of the rock to convey water to the city. At this period, too, Samos was distinguished as the birth-place of Pythagoras; and Anacreon resided for some time at the court of Polycrates. The reign of that monarch, however, came to a disastrous end in 522, when he was treacherously put to death by a Persian satrap. Darius then appointed Sylozen, the brother of Polycrates, to succeed him; but he could only be placed on the throne after a general massacre, which almost reduced the island to a desert. Samos was now virtually subject to Persia, and continued to be so, with a short interval at the time of the Ionian revolt, until the victory of the Greeks at Mycale, B.C. 479, obtained its freedom. It then became a member of the Athenian confederacy; but after a time revolted, and was in consequence reduced to complete subjection by the Athenians. This happened in 439, and from that period till 412 Samos had neither a fleet nor any fortifications; but at the latter date it became a place of importance, and was the head-quarters of the Athenian fleet in their final contest with Sparta. After this time few historical events are connected with Samos. It was celebrated for its school of statuary; and under the Roman empire was a free city, while the temple of Juno enjoyed the privileges of a sanctuary. It is unnecessary to enter minutely into the history of Samos during the middle ages, during which, after having been held for a long time by the Arabs, it was recovered by the Emperor Leo in the thirteenth century, and then successively fell into the hands of the Venetians, Genoese, and Turks. At the time of the Greek insurrection the Samians zealously embraced the side of liberty. They expelled the Turks from the island, which they put into a state of defence, establishing an independent government. Various attempts were made by the Turks to regain the island, but they were all foiled by the courage of the people and the vigilance of the Greek fleet. In the treaty, however, which secured the independence and defined the limits of Greece, Samos was still left to Turkey, and the subsequent efforts that she has made have only secured a partial freedom. The ancient remains in the island are very inconsiderable; they are all near the site of the capital, towards the S.W., and consist chiefly of some fragments of the city walls, some traces of a theatre, a single column of the great temple, and the moles of the harbour. The present population of Samos is estimated at 50,000.

SAMOTHRACE, called by the modern Greeks *Samo-thraki*, an island in the Ægean Sea, about 38 miles S. of the coast of Thrace, and 40 N.W. of the mouth of the Hellespont. It is oval in form, about 8 miles in length by

Samoyedes
||
Samuel,
Books of.

6 in breadth, and has an area of 30 square miles. It is very lofty, the highest point, Mount Fingaree (anciently called *Saoce*), being the most conspicuous object, next to Mount Athos, in this part of the sea, and, except Mount Ida in Crete, the most elevated point in the whole Archipelago. Hence it is represented by Homer as the seat of Neptune when viewing the plains of Troy; and modern travellers have confirmed the accuracy of his description by observing from these plains the island towering up over the low intervening surface of Imbros. Corn, oil, honey, and wax are the principal productions of the island. It has no good harbours, but some anchorages on its coast. Samothrace was chiefly celebrated in ancient times as the seat of the mysteries of the Cabiri, into which many celebrated men were initiated. No important event, either in ancient or in modern history, is connected with the island. Pop. about 15,000, partly Greeks and partly Turks.

SAMOYEDES, a race of people in the Russian empire, occupying the shores of the Arctic Ocean, from the peninsula of Kamin, in the government of Archangel, to the Gulf of Katanska, in the N.E. of that of Yeniseisk. Properly speaking, they are a branch of the Finnic race, but are so widely distinguished from that race that they may be considered a separate one. They are divided into three parts,—Samoyedes of the Great Land, inhabiting the country E. of the Petchora; those of the Little Land, farther west; and those of the Kamin peninsula, the most westerly of all. Their numbers are not great, and they lead a wandering life, subsisting chiefly by fishing and the chase.

SAMSOON, a seaport-town of Asiatic Turkey, pashalic of Sivas, on the shore of the Black Sea, 166 miles W.N.W. of Trebizond. It has mosques, khans, and a small bazaar; and is chiefly remarkable as a place of trade, whence the copper, timber, wheat, &c., of the surrounding country are conveyed to Constantinople. The commercial activity of the place received a great impulse during the Crimean war, on the opposite coast of the Black Sea; but after the peace it relapsed into its old state, and the difficulty of internal communication prevents any permanent advance. Pop. 2000.

SAMUEL. (See SAMUEL, BOOKS OF.)

Name.

SAMUEL, *Books of*. The two books of Samuel were anciently reckoned as but one among the Jews. That they form only one treatise is apparent from their structure. The present division into two books, common in our Hebrew Bibles since the editions of Bomberg, was derived from the Septuagint and Vulgate, in both which versions they are termed the First and Second Books of Kings. Thus Origen (*apud* Euseb. *Hist. Eccles.* vi. 25), in his famous catalogue of the Hebrew Scriptures, names the books of Samuel; so also does Jerome. It was desirable to have short names for the books of Scripture; and as Samuel was a prophet of such celebrity, and had such influence in changing the form of government under which the son of Kish and the son of Jesse became sovereigns, it was natural to name after him the biographical tracts in which the life and times of these royal chieftains are briefly sketched, especially as they at the same time contain striking descriptions of the miracle of his own birth, the oracles of his youth, and the impressive actions of his long career. The selection of this Jewish name might also be strengthened by the national belief of the authorship of a large portion of the work, founded on the language of 1 Chron. xxix. 29.

Contents.

The contents of the books of Samuel belong to an interesting period of Jewish history. The first book of Samuel gives an account of the birth and early call of that prophet to the duties of a seer under Eli's pontificate; describes the low and degraded condition of the people, oppressed by foreign enemies; proceeds to narrate the election of Samuel as judge; his prosperous regency; the degeneracy of his sons; the clamour for a change in the civil constitution; the installa-

tion of Saul; his rash and reckless character; his neglect of, or opposition to, the theocratic elements of the government. Then the historian goes on to relate God's choice of David as king; his endurance of long and harassing persecution from the reigning sovereign; the melancholy defeat and death of Saul on the field of Gilboa; the gradual elevation of the man "according to God's own heart" to universal dominion; his earnest efforts to obey and follow out the principles of the theocracy; his formal establishment of religious worship at Jerusalem, now the capital of the nation; and his series of victories over all the enemies of Judea that were wont to molest its frontiers. The annalist records David's aberrations from the path of duty; the unnatural rebellion of his son Absalom, and its suppression; his carrying into effect a census of his dominions, and the Divine punishment which this act incurred; and concludes with a few characteristic sketches of his military staff. The second book of Samuel, while it relates the last words of David, yet stops short of his death. As David was the real founder of the monarchy and arranger of the religious economy; the great hero, legislator, and poet of his country; as his dynasty maintained itself on the throne of Judah till the Babylonian invasion; it is not a matter of wonder that the description of his life and government occupies so large a portion of early Jewish history. The books of Samuel thus consist of three interlaced biographies,—those of Samuel, Saul, and David.

Samuel.
Books of.

The attempt to ascertain the authorship of this early history is attended with difficulty. Ancient opinion is in favour of the usual theory, that the first twenty-four chapters were written by Samuel, and the rest by Nathan and Gad. Abarbanel, however, and Grotius, suppose Jeremiah to be the author (*Grot. Pref. in 1 Sam*). The peculiar theory of Jahn is, that the four books of Samuel and Kings were written by the same person, and at a date so recent as the thirtieth year of the Babylonish captivity. His arguments, however, are more ingenious than solid (*Introduction, Turner's Translation, § 46*). The fact of all the four treatises being named Books of Kings, Jahn insists upon as a proof that they were originally undivided and formed a single work—a mere hypothesis, since the similarity of their contents might easily give rise to this general title, while the more ancient appellation for the first two was *The Books of Samuel*. Jahn also lays great stress on the uniformity of method in all the books. But this uniformity by no means amounts to any proof of identity of authorship. It is nothing more than the same Hebrew historical style. The more minute and distinctive features, so far from being similar, are very different. The books of Samuel and Kings may be contrasted in many of those peculiarities which mark a different writer. The books of Samuel have an authorship of their own—an authorship belonging to a very early period. While their tone and style are very different from the later records of Chronicles, they are also dissimilar to the books of Kings. They bear the impress of a hoary age in their language, allusions, and mode of composition. The insertion of odes and snatches of poetry, to enliven and verify the narrative, is common to them with the Pentateuch. The minute sketches and vivid touches with which they abound prove that their author "speaks what he knows, and testifies what he has seen." As if the chapters had been extracted from a diary, some portions are more fully detailed and warmly coloured than others, according as the observer was himself impressed.

From public and acknowledged sources has the compiler fetched his materials, in the shape of connected excerpts. The last of the prophetic triumvirate might be the redactor or editor of the work, and we would not date its publication later than the death of Nathan, while the original biographies may have been finished at the period of David's decease. But certainty on such a subject is not to be attained.

Sana
||
Sanadon.

Probability is all that we dare assert. The compiler has in all probability framed out of authoritative documents a consecutive history, not dwelling on all events with equal interest, but passing slightly over some, and formally detailing others with national relish and delight.

Credibility The authenticity of the history found in the books of Samuel rests on sufficient grounds. Portions of them are quoted in the New Testament (2 Sam. vii. 14, in Heb. i. 5; 1 Sam. xiii. 14, in Acts xiii. 22). References to them occur in other sections of Scripture, especially in the Psalms, to which they often afford historic illustration. It has been argued against them that they contain contradictory statements. The old objections of Hobbes, Spinoza, Simon, and Le Clerc are well disposed of by Carpzovius (*Introductio*, p. 215). Some of these supposed contradictions we have already referred to; and for a solution of others, especially of seeming contrariety between the books of Samuel and Chronicles, we refer with satisfaction to Davidson's *Sacred Hermeneutics*, p. 544, &c. Some of the objections of Vatke, in his *Bibl. Theol.*, are summarily disposed of by Hengstenberg (*Die Authentie des Pentat.*, vol. ii., p. 115), who usually chastises such adversaries with a whip of scorpions. Discrepancies in numbers, and sometimes in proper names, are the most common; and it is well known that textual errors in numeration are both most frequently and most easily committed.

SANA, a town of Arabia, the capital of Yemen or Arabia Felix, 4000 feet above the sea, in a beautiful valley extending from N. to S., from 6 to 9 miles broad, and bounded on either side by mountains and table-lands, 110 miles N.N.E. of Hodeida; N. Lat. 15. 22., E. Long. 44. 31. The streets are in general narrow, and the principal one is crossed by a handsome bridge, as in rainy weather a stream of water runs through it. The houses are large, and those of the upper classes have windows filled with fine stained glass. A wall, about 5½ miles in circuit, surrounds the town, and has a few guns; but it is in a very ruinous condition. There are about 20 mosques, in general very splendid, and many of them surmounted by gilt domes. Sana has also a bazaar, and baths similar to those of Egypt. But the principal buildings are the two large palaces of the imam, which have extensive gardens attached to them, the whole being surrounded with fortifications. The architecture of these edifices is Saracenic, with an intermixture of round and pointed arches, but they are devoid of all superfluous ornaments. Most of the artisans in Sana are Jews, who live in a separate quarter of the town, and are subject to much oppression, paying heavy taxes for permission to reside in the town, and for the possession of gardens or vineyards. They, as well as the Banians, who form a large proportion of the population, are obliged to conceal their wealth, and they live by the sale of jewellery, gunpowder, spirits, &c. The most important and wealthy class in Sana are the merchants. The principal article of export is the coffee grown in the vicinity; while tobacco, thread, silk, velvet, glass, dates, spices, sugar, &c., are imported. Sana has been governed by an imam ever since the Turks were expelled from this part of Arabia, in the reign of Solymán the Magnificent. Some ancient inscriptions have been discovered here. Pop. about 40,000.

SANADON, NOËL ETIENNE, a Jesuit, and professor of

humanity at Caen, was born at Rouen in 1676. He became acquainted with Huet, Bishop of Avranches, whose taste for literature and poetry was similar to his own. Sanadon afterwards taught rhetoric at the university of Paris, and upon the death of Du Cerceau he was entrusted with the education of the Prince of Conti. In 1728 he was made librarian to Louis XIV., an office which he retained to his death, which took place on the 21st of September 1733, in the fifty-seventh year of his age.

His works are, *Poesies Latinæ*, in 12mo, 1715, reprinted by Barbou, in 8vo, 1754. These poems consist of odes, elegies, and epigrams on various subjects. A translation of Horace, with remarks, in two vols. 4to, printed at Paris in 1727. The best edition of this work was printed at Amsterdam in 1735 in 8 vols. 12mo, in which are also inserted the versions and notes of Madame Dacier, whose version of Horace is decidedly inferior to that of Sanadon, although his version is rather a paraphrase than a faithful translation, and possesses very few of the beauties of Horace. A collection of *Discours*, delivered at different times, afford strong proofs of his knowledge of oratory and poetry. A book entitled *Prières et Instructions Chrétiennes*, 1752, gives good evidence of genuine piety.

SANCHEZ, FRANCISCO, commonly called "El Brocense," the best classical scholar of his day in Spain, was born at Las Brozas in Estremadura in 1523. After taking his bachelor's degree at Valladolid, he went to Salamanca, where he obtained the chair of rhetoric in 1554. He likewise taught Greek and Latin, and had the honour to be spoken of in the highest terms by such learned men as Justus Lipsius and Scioppius. Lipsius, after designating him the "divine" and the "admirable," calls him "the Mercury and the Apollo of Spain." Having edited several classical authors, and having taken his doctor's degree, he devoted all his time to the great work *Minerva, seu de Causis Lingue Latine Commentarius*, which appeared in 1587, and which has frequently been reprinted. This work raised the author's reputation to the highest pitch. He resigned his chair of rhetoric into the hands of his son-in-law in 1593, and died on the 17th January 1601, aged 77.

Sanchez wrote a great many smaller works, which are contained in the 4-vol. edition of his minor writings of 1766. Prefixed to the first volume is a Life of the author by Mayans.

SANCHEZ, FRANCISCO, a physician and sceptical philosopher, who is frequently confounded with the eminent classic of the same name, was born of Jewish parents during the latter half of the sixteenth century at Bracara, or, according to others, at Tuy, on the frontiers of Portugal. He pursued his studies for a time at Bordeaux, but his father having been exiled while he was still young, he completed his medical education at Rome. In 1573 he graduated in medicine at Montpellier, took up his residence at Toulouse, and professed philosophy for twenty-five years and medicine for eleven with remarkable success. He died in 1632.

Sanchez has left the following philosophical work, which assigns him a place beside his sceptical contemporaries, Montaigne and Charron, viz., *Tractatus de multum nobili et prima universali scientia, quod nihil scitur*, 4to, Lyons, 1581; Franc. 1628; Rotterdam, 1649. A complete edition of his writings, medical and philosophical, will be found under the title *Opera Medica*, Toulouse, 1636. Refutations of the scepticism of Sanchez were attempted by Ulrich Wild, Leipsic, 1664, and by Daniel Gartmarck, Stettin, 1665. (See *Dict. des Phil. Sciences*.)

SANCHUNIATHON (Σαγχουνιάθων), a Phœnician philosopher and historian, who is said by some to have flourished about the time of the Trojan war, and according to others, about the time of Semiramis. Of this most ancient writer the only remains extant are various fragments of cosmogony, and of the history of the gods and

Sanchez
||
Sanchunia-
thon.

Sanchuni-
athon.

first mortals, preserved by Eusebius and Theodoret, both of whom speak of Sanchuniathon as an accurate and faithful historian; and the former adds that his work, which was translated by Philo-Byblus from the Phœnician into the Greek language, contains many things relating to the history of the Jews which deserve great credit, both because they agree with the Jewish writers, and because the author received these particulars from the annals of Hierombalus, a priest of the god *Ἰεῦός* (? *Jehovah*).

Several modern writers of great learning, however, have called in question the very existence of Sanchuniathon, and have contended, with much plausibility, that the fragments which Eusebius adopted as genuine upon the authority of Porphyry were forged by that author or by the pretended translator Philo, from enmity to the Christians, and that the pagans might have something to show of equal antiquity with the books of Moses. These opposite opinions have produced a controversy that has filled volumes, and of which our limits would hardly admit of an abstract. We shall therefore in few words state what appears to us to be the truth, and refer such of our readers as are desirous of fuller information to the works of the authors mentioned below.¹

The controversy respecting Sanchuniathon resolves itself into two questions: *first*, Was there in reality such a writer? and, *second*, Was he of the very remote antiquity which his translator claims for him?

1. Now that there was really such a writer, and that the fragments preserved by Eusebius are indeed parts of his history, interpolated perhaps by the translator, we are compelled to believe.² Eusebius, who admitted them into his work as authentic, was one of the most learned men of his age, and a diligent searcher into antiquity. Father Simon of the oratory imagines (*Bib. Crit.*, vol. i., p. 140) that the purpose for which the history of Sanchuniathon was forged was to support paganism by taking from it its mythology and allegories, which were perpetually objected to it by the Christian writers. But this learned man totally mistakes the matter. The primitive Christians were too much attached to allegories themselves to rest their objections to paganism on such a foundation. What they objected to in that system was the immoral stories told of the priests. Is it conceivable that a writer so acute as Porphyry, or indeed that any man of common sense either in his age or in that of Philo, would forge a book filled with such stories as these in order to remove the Christian objections to the immoral characters of the pagan divinities? The very supposition is impossible to be made. Nor let any one imagine that Sanchuniathon is here writing allegorically, and by his tales of Ouranos, and Gé, and Kronus, is only personifying the heaven, the earth, and time. On the contrary, he assures us that Ouranos, or Epigeus, or Autochthon (for he gives him all these names), was the son of one Eliaun or Hypsistos, who dwelt about Byblus, and that from him the element which is over us was called heaven on account of its excellent beauty, as the earth was named Gé after his sister and wife. And his translator is very angry³ with the Neoteric Greeks, as he calls them, because that, "by a great deal of force and straining, they laboured to turn all the stories of the gods into allegories and physical discourses." This proves unanswerably that the author of this book, whoever he was, did not mean to veil the great truths of religion under the cloak of mythological allegories; and therefore, if it was forged by Porphyry in support of paganism, the forger so far mistook the state of the question

between him and his adversaries that he contrived a book, which, if admitted to be ancient, totally overthrew his own cause.

2. The next thing to be inquired into with respect to Sanchuniathon is his antiquity. Did he really live and write at so early a period as Porphyry and Philo pretend? We think he did not; and what contributes not a little to confirm us in our opinion is that mark of national vanity and partiality common to after-times, in making the sacred mysteries of his own country original, and conveyed from Phœnicia into Egypt. This, however, furnishes an additional proof that Porphyry was not the forger of the work; for he well knew that the mysteries had their origin in Egypt (see MYSTERIES), and would not have fallen into such a blunder. He is guilty, indeed, of a very great anachronism when he makes Sanchuniathon contemporary with Semiramis, and yet pretends that what he writes of the Jews is compiled from the records of Hierombalus the priest of the god *Jeuo*; for Bochart has made it appear in the highest degree probable⁴ that Hierombalus or Jerombaal is the Jerub-baal or Gideon of Scripture. Between the reign of Semiramis and the Trojan war a period elapsed of near eight hundred years, whereas Gideon flourished not above seventy years before the destruction of Troy. But supposing Sanchuniathon to have really consulted the records of Gideon, it by no means follows that he flourished at the same period with that judge of Israel. He speaks of the building of Tyre as an ancient thing, while our best chronologers⁵ place it in the time of Gideon. Indeed, were we certain that any writings had been left by that holy man, we should be obliged to conclude that a large tract of time had intervened between the death of their author and their falling into the hands of Sanchuniathon; for surely they could not in a short period have been so completely corrupted as to give any countenance to his impious absurdities. His atheistic cosmogony he does not indeed pretend to have got from the annals of the priest of *Jeuo*, but from records which were deposited in his own town of Berytus by Thoth, a Phœnician philosopher, who was afterwards made king of Egypt. But surely the annals of Gideon, if written by himself, and preserved pure to the days of Sanchuniathon, must have contained so many truths of the Mosaic religion as must have prevented any man of sense from adopting so impossible a theory as Thoth's, although sanctioned by the greatest name of profane antiquity. Stillingfleet indeed thinks it most probable that Sanchuniathon became acquainted with the most remarkable passages of the life of Jerub-baal from annals written by a Phœnician pen. He observes, that immediately after the death of Gideon, the Israelites, with their usual proneness to idolatry, worshipped Baal-berith, or the idol of Berytus, the town in which Sanchuniathon lived; and from this circumstance he concludes that there must have been such an intercourse between the Hebrews and the Berytians, that in process of time the latter people might assume to themselves the Jerub-baal of the former, and hand down his actions to posterity as those of a priest instead of a great commander. All this may be true; but if so, it amounts to a demonstration that the antiquity of Sanchuniathon is not so high by many ages as that which is claimed for him by Philo and Porphyry; though he may still be more ancient, as we think Vossius has proved him to be, than any other profane historian whose writings have come down to us either entire or in fragments.

A useful edition of the fragments, said to be of Sanchu-

¹ Bochart, Scaliger, Vossius, Cumberland, Dodwell, Stillingfleet, Mosheim's Cudworth, and Warburton.

² Of these indeed there are several proofs. Philo makes Sanchuniathon speak of Byblus as the most ancient city of Phœnicia, which, in all probability, it was not. We read in the book of Judges of Berith or Berytus, the city where Sanchuniathon himself lived; but not of Byblus, which was the native city of Philo, and to which he is therefore partial. He makes him likewise talk of the Greeks at a period long before any of the Grecian states were known or probably peopled.

niathon, were published by J. C. Orelli, Leipzig, 1826; and in 1835 an MS. was said to have been discovered in Portugal of the nine books of Philo's translation of that ancient historian. This discovery caused immense squabbling among the German critics. The majority of them pronounced it to be spurious. Wagenfeld, the two Grotenfends, Schmidt, and Movers, may be consulted regarding it. On the general subject the reader may refer to J. A. Fabricius, *Biblioth. Græc.*, vol. i. p. 222.

SANCROFT, WILLIAM, archbishop of Canterbury, was born at Fresingfield in Suffolk in 1616, and admitted into Emanuel College, Cambridge, in 1633. In 1642 he was elected a fellow; but was ejected from his fellowship for refusing to take the Solemn League and Covenant. In 1660 he was chosen one of the university preachers, and in 1663 was nominated to the deanery of York. In 1664 he was installed dean of St Paul's. In this situation he set himself with unwearied diligence to repair the cathedral, till the fire of London in 1666 employed his thoughts on the more noble undertaking of rebuilding it, to which he gave L.1400. He also rebuilt the deanery, and improved its revenue. In 1668 he was admitted archdeacon of Canterbury, upon the king's presentation. In 1677, being now prolocutor of the convocation, he was unexpectedly advanced to the archbishopric of Canterbury. In 1687 he was committed to the Tower, with six other bishops, for presenting a petition to the king against reading the declaration of indulgence. Upon King James II.'s withdrawing himself, he concurred with the lords in a declaration to the Prince of Orange for a free parliament, and due indulgence to the Protestant dissenters. But when that prince and his consort were declared king and queen, his grace refused to take the oath to their majesties, and was suspended and deprived. He retired to his birth-place, where he lived in a very private manner till his death, which took place in 1693. His learning, integrity, and piety made him an exalted ornament of the church. He published a volume in 12mo, entitled *Modern Politics*, taken from Machiavelli and other authors; and also *Familiar Letters* to Mr (afterwards Sir Henry) North. He is said by Lord Macaulay to have been "an honest, pious, narrow-minded man." (*History of England*, vol. ii. p. 7, 1858.)

SANCTORIUS, the ordinary name by which SANTORIO, a distinguished Italian physician is known, was born at Capo d'Istria in 1561. Having taken his medical degree at Padua, he subsequently settled at Venice, where he practised his profession with the greatest success. His reputation having travelled back to Padua, he was in 1611 recalled from Venice, and appointed professor of the theory of medicine in his parent university. Sanctorius continued to lecture here for the next thirteen years, but having been frequently called to Venice on important medical business during that time, and feeling the fatigue of travelling gradually become more and more irksome, he was induced to resign his professorship, for which he continued however to receive the salary. Settling in Venice, he continued his medical practice till his death in 1636, in his seventy-fifth year. He was interred in the cloister of the Servites, where a marble statue marks his tomb.

The observations of Santorio on insensible perspiration rendered his name famous throughout Europe. He was a man of true genius, alike devoid of the pompous medical ignorance of his co-temporaries, and of the blind reverence for opinion peculiar to his century. He was author of six separate works, some of them of great value, particularly *Methodus Vitæ et Errorum omnium qui in Arte Medicâ contingunt*, Libri xv., Ven. 1602; *Commentarius in Artem Medicinalem Galeni*, Venet. 1612; *Ars de Staticâ Medicinâ*, Venet. 1614. This work has been frequently translated. It has been done into Italian by Baglivi, Rome, 1704; by Cogrossi, Padua, 1724; by Chiari, Venice,

Sandbach

Sanderson.

1720; into French by Le Breton, Paris, 1722; into German by Timmius, Bremen, 1736; and into English by J. D., London, 1696, and by Dr Quincy, London, 1712. *Commentarius in Primam Fen primi libri canonis Avicennæ*, Venet. 1626; another *Commentarius*, of little value, and a *Liber de Remediis Inventione*, Venet. 1629, which contains a curious account of some post mortem examinations. The life of Sanctorius was written in Latin by A. Capelli, Venice, 1750; and his whole works appeared at Venice in 1660, in 4 vols. 4to.

SANDBACH, a market-town of England, in Cheshire, on a hill near the right bank of the Wheelock, 24 miles E.S.E. of Chester. There is an old parish church in the perpendicular style, which has been partially rebuilt; also Methodist and Baptist churches; a grammar-school founded in 1577, national and other schools, &c. Shoes and silk are manufactured here. Pop. (1851) 2752.

SANDBY, PAUL, founder of the English school of water-colour painting, was sprung from a branch of the Sandbys of Babworth, and was born at Nottingham in 1725. After commencing his artistic studies in London, in 1746 he was appointed by the Duke of Cumberland draughtsman to the survey of the Highlands. His skill as an engraver brought him under the notice of Sir Joseph Banks, who gave him his patronage, and subsequently commissioned him to bring out in aquatinta (a method of engraving then peculiar to Sandby) forty-eight plates drawn during a tour in Wales. Sandby displayed considerable power as a caricaturist in his attempt to ridicule the opposition of Hogarth to the plan for creating a public academy for the arts. Having been a member of various artistic societies, he was chosen a foundation-member of the Royal Academy in 1768, and during the same year was appointed chief drawing-master to the Royal Military Academy at Woolwich. He held this situation till his death, and during that time he brought forth many artists, who afterwards gained a name in their profession. Sandby will be best remembered, however, by his water-colour painting. While it wanted the richness and brilliancy of modern water-colour, he nevertheless impressed upon his art the originality of his mind; and in his later pieces, in particular, decided progress is observable in richness and in harmony of tinting. His etchings, such as "Cries of London" and Ramsay's "Gentle Shepherd," and his plates, such as Tasso's "Jerusalem Delivered," are both numerous and carefully executed. He died in London on the 9th November 1809.

SANDEMANIANS. See GLASSITES.

SANDERSON, ROBERT, bishop of Lincoln, was born at Rotherham, in Yorkshire, on the 19th of September 1587. He was descended of an ancient family, and attended the grammar-school at Rotherham, where he made such wonderful proficiency in the languages that at thirteen it was judged proper to send him to Lincoln College, Oxford. In 1608 he was appointed logic-reader in the same college. He took orders in 1611, and was promoted successively to several benefices. Archbishop Laud recommended him to Charles I. as a profound casuist; and that monarch, who seems to have been a great admirer of casuistical learning, appointed him one of his chaplains in 1631. The king regularly attended his sermons, and was wont to say that he "carried his ears to hear other preachers, but his conscience to hear Mr Sanderson." Chancing to be with the king at Oxford in 1636 he was made a D.D. In 1642 Charles created him regius professor of divinity at Oxford, with the canonry of Christ Church annexed. But the civil wars prevented him until 1646 from entering on the office; and in 1648 he was ejected by the visitors which the Parliament had commissioned. When the parliament proposed the abolition of the episcopal form of church government, as incompatible with monarchy,

Sandoval. Charles desired him to take the subject under his consideration, and deliver his opinion. He accordingly wrote a treatise entitled *Episcopacy, as established by Law in England, not prejudicial to Regal Power*, 1661. The king afterwards advised him to publish cases of conscience. He replied that "he was now grown old, and unfit to write cases of conscience." The king said, "It was the simplest thing he had ever heard from him; for no young man was fit to be a judge, or write cases of conscience." Izaak Walton, who wrote the life of Dr Sanderson, informs us, that in one of these conferences the king told Sanderson, or one of the rest who was then in company, that "the remembrance of two errors did much affect him, which were his assent to the Earl of Strafford's death, and the abolishing of episcopacy in Scotland; and that if God ever restored him to the peaceable possession of his crown, he would prove his repentance by a public confession and a voluntary penance, by walking barefoot from the Tower of London, or Whitehall, to St Paul's Church, and would desire the people to intercede with God for his pardon." Boyle, having read a work of Dr Sanderson's, entitled *De Juramenti Obligatione*, 1661, was so much pleased that he requested the author to write his *Cases of Conscience*, with which Sanderson complied, 1678. When Charles II. was reinstated on the throne, he recovered his professorship and canonry, and soon afterwards was promoted to the bishopric of Lincoln. During the two years and a half in which he possessed this new office, he spent a considerable sum in augmenting poor vicarages, and in repairing the palace at Budgen. He died on the 29th of January 1662-63, in his seventy-sixth year. His works not already mentioned are as follows:—In 1615 he published *Logicæ Artis Compendium*, which was the system of lectures he had delivered in the university when he was logic-reader; *Sermons*, amounting in number to thirty-six, printed in 1681, folio, with the author's Life by Walton; *De Obligatione Conscientiæ*; *Censure of Mr Antony Ascham his book of the Confusions and Revolutions of Government*; *Pax Ecclesiæ*, concerning Predestination, or the five points. Besides these he wrote two *Discourses* in defence of Usher's writings. (See *The Works of Robert Sanderson, D.D.*, now first collected by Dr William Jacobson, in 6 vols., Oxford, 1854.)

SANDOVAL, FRAY PRUDENCIO DE, a bishop and historian of Spain of considerable merit, was born according to some at Valladolid, according to others at Monterey, in Galicia, in 1560. Having been educated for the church he took monastic orders, and passed several years in the constant study of the antiquities of Spain. Sandoval was soon after made abbot of San Isidore and historiographer to Philip III., when he responded to a royal request to continue the *Cronica General* of Morales, by carrying down that history from 1037 to the death of Alfonso VII. in 1097, published in 1600. But by far the most valuable work which Sandoval wrote is his history of Charles V., entitled *Historia de la Vida y Hechos del Emperador Carlos V.*, Valladolid, 1604 and 1605; Pamplona, 1614; Antw. 1681. Of this work there are two abridgments in English,—one by James Wandsworth, London, 1652; the other by Captain John Stevens, London, 1703. Sandoval was rewarded for his labour by the bishopric of Tuy, and shortly after by that of Pamplona in 1612. The whole of his life almost was spent in the exploration of the public archives and libraries of his native country. He died at Pamplona on the 17th of March 1621, aged sixty-one years. Bishop Sandoval, besides other works, edited a number of chronicles of the twelfth century, which will be found in *Las Cronicas de los Quatro Obispos*, fol. 1615 and 1634. Ticknor (*History of Spanish Literature*, vol. iii. 139, 1849), in speaking of the greatest work of Sandoval, characterizes it as too long. "It fills," he says, "as many pages as the

entire work of Mariana, and, though written with simplicity, is not attractive in its style. His prejudices are strong and obvious. Not only the monk, for he was a Benedictine, and enjoyed successively two very rich bishoprics, but the courtier of Philip III. is constantly apparent. . . . Still, the history of Sandoval is a documentary work of authority much relied on by Robertson, and one that, on the whole, by its ample and minute details, gives a more satisfactory account of the reign of Charles V. than any other single history extant."

SANDRART, JOACHIM VON, a painter and artistic biographer, was born of an ancient and noble family at Franckfurt-on-the-Main in 1606. He devoted himself early to the arts, and received his first lessons from Théodore de Bry. At the age of fifteen he set out for Prague to learn the art of engraving from Sadeler; but that artist advising him to apply himself to painting, he went to Utrecht, where he entered the school of Gerhard Honthorst. Here he made rapid progress, and was soon able to assist his master in his more important paintings. Descamps and Pilkington both say that Sandrart accompanied his master to England, but Bryan can find no evidence of this. At all events, he proceeded to Italy in 1627, and spent some time at Venice, copying the paintings of Titian and Paul Veronese. He afterwards visited Bologna, Florence, and Rome, studying as he went the works of the great Italian masters. Cardinal Barberini was commissioned by the king of Spain to procure for him twelve paintings by the best masters then living, when Sandrart had the honour to be chosen, together with Guido, Guercino, Dominichino, N. Poussin, &c., to execute those pictures for the Escorial. After visiting Naples, Sicily, and Malta, Sandrart returned to Germany, whither his fame had preceded him. The plague which then raged in that country drove him to seek an asylum elsewhere, and he accordingly settled in Amsterdam, where he executed many of his largest paintings, and among others the entry of Mary de Medicis into that town. Sandrart had held by heritage a piece of landed property at Stockau, near Ingoldstadt, which had been much devastated by the late wars. This circumstance led him to part with his land, and settle at Augsburg. He established himself at Nürnberg in 1672, where he was held in great esteem by the emperor and many of the minor princes of Germany. He was engaged on his picture of the "Last Judgment" when he died at Nürnberg in 1688. Here he published five works in all, of which the best known and most esteemed is his *Academia Artis Pictoria*, 1683. His paintings are not now much sought after; but his *Lives of the Painters*, ancient and modern, is still admired.

SANDUSKY, a town of the United States of North America, capital of Erie county, Ohio, on the south shore of Sandusky Bay, an inlet of Lake Erie, 110 miles N. by E. of Columbus. It is built on ground rising gradually from the bay, which forms an excellent harbour, 20 miles long and 5 or 6 across. Close to the town are inexhaustible quarries of the best limestone, of which many of the handsome edifices that adorn the town are built. There are numerous churches, banks, and newspaper offices, a court house, jail, and several schools. The wharves of Sandusky are commodious and well built, and during the most part of the year they are thronged with vessels arriving and departing. Iron and machinery are the principal manufactures of the place. It is also one of the chief emporiums for the lake commerce, and has communication by railway both with the west and the east. The imports in 1852 amounted in value to L.8,520,014, and the exports to L.3,934,540; while the shipping of the port in the same year had a tonnage of 5887. Pop. (1850) 5087, (1853) about 10,000.

SANDWICH, a market-town, cinque port, municipal and parliamentary borough of England, in the county of Kent, on the right bank of the Stour, about 3 miles from

Sandrart

Sandwich.

Sandwich
Islands
||
San Felipe.

the sea, 12 E. of Canterbury, and 68 E. by S. of London. It stands in a sandy, marshy region, occupied chiefly with market-gardens, and has narrow, well-paved streets, lined with old irregular houses. Part of the ancient town walls, and one of the gates, still remain. There are several conspicuous public buildings in the town. Among these is the massive old church of St Clement, with a square Norman tower, the Elizabethan guild-hall, modern jail, almshouses, national schools, hospitals, and places of worship, besides three belonging to the Established church, for Baptists, Independents, and Wesleyans. A grammar-school was founded here in the time of Queen Elizabeth, with exhibitions to Oxford, but it has at present no scholars. Breweries, malt-houses, and tan-yards are the principal manufacturing establishments; and felt, coarse towellings, and sackcloth are also made. Sandwich was formerly an important seaport, but has decayed since the harbour began to be choked up with sand. There is still some trade with Norway, Sweden, and the Baltic in timber and iron; while wool, malt, leather, and agricultural produce are likewise exported. Only small vessels can now come up to the town. Sandwich is governed by a mayor, four aldermen, and twelve councillors; and the borough, which includes Deal and Walmer, returns two members to Parliament. It was early a place of importance, and probably rose after the decline of the Roman Rhutupium, or Richborough. Several times Sandwich has been taken and plundered by the French. In the reign of Elizabeth a number of Flemish refugees settled here. Pop. (1851) of the town 2966, of the parliamentary borough 12,710.

SANDWICH ISLANDS. See POLYNESIA.

SANDYS, GEORGE, an elegant English poet, the youngest son of Dr Edwin Sandys (Sandes or Sands he also wrote it), archbishop of York, was born at the palace of Bishopsthorpe in 1577. In 1589, the year after his father's death, he entered St Mary Hall, Oxford, and afterwards, as Wood supposes, he became a member of Corpus Christi, where his elder brother Edwin was educated under Dr Hooker. Izaak Walton, in his life of Hooker, tells us that "this Edwin was afterwards Sir Edwin Sandys, and as famous for his *Speculum Europæ* as his brother George for making posterity beholden to his pen by a learned relation and comment on his dangerous and remarkable *Travels*, and for his harmonious translation of the *Psalms of David*, the *Book of Job*, and other poetical parts of Holy Writ, into most high and elegant verse." His *Travels*, which were published in 1615, were dedicated to Charles, Prince of Wales, and bore the title of *A Relation of a Journey begun in 1610, in Four Books, containing a Description of the Turkish Empire, of Egypt, of the Holy Land, and of the remote parts of Italy and Islands adjoining*. Sandys appears to have succeeded his brother as treasurer to the English colony of Virginia, where he prepared his translation of the *Metamorphoses* of Ovid. In 1636-8 appeared his poetical version of the books of Psalms, Job, Ecclesiastes, &c.; and in 1639 his *Christ's Passion*, a tragedy by Grotius. His last work, the poetical translation of the *Song of Solomon*, was published in 1642. He died at Braxley Abbey in Kent, in March 1643-44.

The merits of George Sandys as a poetical translator stand very high. Although now fallen considerably into neglect, he seems to have been duly appreciated by the more discerning of his contemporaries. Waller describes him as having enriched our vulgar tongue; and Dryden, the best judge of his day in matters relating to poetry, pronounced him "the best versifier of the former age." This judgment has been recently confirmed by Warton and Lisle Bowles: *Selections from Sandys's Metrical Paraphrases* have been published, with a Life of the Poet by the Rev. H. J. Todd, London, 1839.

SAN FELIPE, a town of Venezuela, in the depart-

ment of Caraccas, near the left bank of the Yuracuy, 60 miles W.N.W. of Valencia. It is well built, but lies in a low, unhealthy region, liable to inundations. Coffee, cacao, and rice are produced here, and there is an active trade. Pop. 7000.

San Felipe
||
San Francisco.

SAN FELIPE DE ACONCAGUA, capital of the province of Aconcagua in Chili, on the right bank of the river of the same name, 40 miles north of Santiago. It is well built, and is considered one of the finest towns in the interior. There are here three convents, and in the vicinity copper and gold mines. Pop. 8000.

SAN FRANCISCO, the capital of a county of the same name, and chief commercial city of California, in the United States of North America, at the mouth of the splendid bay of San Francisco, through which the river Sacramento issues into the sea, N. Lat. 37. 48., W. Long. 122. 26. It occupies the northern extremity of a tongue of land that encloses the bay on the west; and its site consists of a sandy plain, gently sloping from the hills behind down to the bay. The city was originally built round a semi-circular cove facing the north-east, but this is now covered with warehouses erected on piles, and the rapidly increasing buildings are extending backwards from the water and climbing the hills behind, which are only about half a mile from the shore. From Telegraph Hill to the north, a magnificent view is obtained over the city and surrounding country. To the west lies the ocean and the entrance of the bay; to the north its northern arm, leading up the Sacramento river, and ever studded with steamers; to the east, beyond the broad sheet of water, a panorama of wooded hills, with the cone of Monte Diabolo in the distance; and to the south the city itself, with its perpetual bustle and activity, its wharves crowded with shipping from all parts of the world. The streets are all regularly laid out, crossing one another at right angles; but the buildings exhibit the utmost variety in the form and materials of their construction, though brick is now beginning to be most generally used. Some of the public buildings, such as the churches, schools, hospitals, theatres, &c., are equal to any in the United States; and many of the hotels and shops are large and splendid. But the rapidity of the changes that come over the appearance of San Francisco renders it vain to give any detailed description. Many important manufactures are carried on in the town. There are two sugar-houses, a paper mill, two steam barrel factories, oil-works, and shipbuilding yards; while agricultural implements, furniture, carriages, tubs, pails, musical instruments, &c., are also made here.

The history of the place, especially its recent rapid rise, is not a little remarkable. Its original name was *Yerba Buena*, and it first rose in connection with one of the Spanish mission settlements, called San Francisco, founded in 1776. From that period till 1831 the settlement continued to flourish under the Spanish, and latterly under the Mexican, government; but the disturbances which then agitated the country drove away the Indians, and reduced the settlement to ruins. A new city was founded in 1839, but the population in 1845 did not exceed 150. Numerous settlers from the United States began to flock hither, even before California was ceded to that country in 1848. But in the December of the previous year a new era opened for San Francisco with the discovery of gold. No sooner was the fact generally known, in the next spring, than the city was almost deserted for the diggings; trade was at an end, and all business seemed to have ceased. But this did not last long, for in the month of August eager crowds of emigrants began to arrive, the harbour was thronged with ships, and the city far more than before alive with bustle and din. Building was soon commenced with vigour, the value of property rose rapidly, and in little more than a year the population had risen to more than 15,000. De-

San Fran-
cisco.

structive fires broke out on several occasions, and laid large portions of the city in ashes; but these injuries were speedily repaired. By these calamities, as well as by a reckless expenditure, the financial affairs of the city were reduced to a very low state; but by the imposition of heavy taxes the credit was restored from a state of almost hopeless bankruptcy. So much gold poured into the town as to render it necessary in 1853 to establish a mint in San Francisco. Its operations since it commenced in 1854 have been as follows:—

Years.	GOLD.			SILVER.	
	Bars.	Fine Bars.	Bars and Coin.	Bars.	Total.
1854	L. 1,187,811	L. 1,232	L. 2,027,408	L. ...	L. ...
1855..	681,371	18,493	4,366,303	...	34,180
1856 .	634,790	25,442	5,899,066	4915	41,793

Other ports.....	2	813
Total.....	1441	467,529

The imports from different countries vary considerably in different years: those from the whale fishery have regularly fallen off for the last four years; those from Australia have remained stationary; those from Mexico, China, the East Indies, and South America have increased; and

those from Vancouver's Island have been almost entirely created since the discovery of gold there. The imports from foreign countries to San Francisco were in 1856 valued at L.1,520,795; in 1857 at L.1,903,624; and in 1858 at L.1,872,856. The most important articles of import are rice, coffee, sugar, wine and spirits, timber, and coal. The following table exhibits the tonnage of vessels that left San Francisco in the last three years for various ports, exclusive of the Pacific states of the Union.

San Francisco is now rapidly rising above its former condition of being a mere landing-place for the gold-diggers; the population is becoming more settled; the turbulence and reckless speculation of the first miners have given place to order and security; the agricultural wealth of the country is being developed, and the trade in gold is every year forming a smaller proportion of the whole trade of the place. The population of San Francisco, which according to the State census of 1852 was 34,776, was estimated in 1853 to be from 50,000 to 60,000.

SANGA, a town of Japan, in the island of Kioo Sioo, in a fertile plain at the head of the bay of Simbara, 55 miles N.E. of Nangasaki. It is large and populous, and encircled by fortifications. Its broad, straight streets are traversed by streams and canals. There are here important manufactures of porcelain.

SANGALLO, properly GIAMBERTI, a family of distinguished architects, of whom the eldest was GIULIANO GIAMBERTI, who was born at Florence in 1443. Having been early sent, with his brother Antonio, to an ingenious carver

Sanger-
hausen.

in wood, he afterwards renounced this profession for that of military engineer to Lorenzo de' Medici. Giuliano now resolved to pursue architecture, and had an early opportunity of displaying his skill on the cloister of the Church of Santa Maddalena de' Pazzi at Florence, which he ornamented with a row of Ionic pillars of peculiar capitals, such as were not then known. Being afterwards commissioned by Lorenzo to erect a convent near the gate of San Gallo, the architect received the title of *Da San Gallo* at first in jest from his master, but subsequently he adopted it, together with his whole family. Among his numerous works was a palace erected at Savona, now the convent of Santa Chiara, for his patron the Cardinal della Rovere. On the death of Bramante, he was offered the appointment of architect of St Peter's, which he was obliged to decline from growing infirmities. He died at Florence in 1517, aged seventy-four.

ANTONIO, brother of Giuliano, attracted by his success, likewise became an architect. Besides converting Hadrian's mausoleum at Rome into its present form of the Castle of St Angelo, and erecting several fortresses for Pope Alexander VI., he likewise built several churches, of which that of the Madonna at Montepulciano is considered the best specimen of his art. He died in 1534, and was interred beside his brother Giuliano, in the burying-ground of the Giamberti family, in the church of Santa Maria Novella.

ANTONIO, the most noted architect of the family of SANGALLO, was a nephew, on his mother's side, to the two preceding, but whose father was Bartolomeo Picconi, a cooper of Mugello. He was born in 148—, but what precise year in the decade cannot now be ascertained. Originally a carpenter, he was subsequently led to visit Rome, whither he had been drawn by the fame of his uncles. As those noted architects left the capital shortly after his arrival, he had the good fortune to find a protector in Bramante, then a man well advanced in years. He soon drew upon himself the notice of Cardinal Farnese, afterwards Paul III., for whom he built a splendid mansion in the Campo de' Fiori, which would have been sufficient to have established his reputation. He subsequently erected numerous private palazzi, and among others his own house in the Strada Giulia, now the Palazzo Sacchetti. He was employed on military architecture for a number of years at Civit  Vecchia, Parma, Piacenza, Ancona, &c.; when he was, on the death of Peruzzi, chosen sole architect for the completion of St Peter's. He modelled a design of this splendid edifice, nearly 20 English feet in length, which, although broken into a multiplicity of parts, are yet agreeably proportioned, and the *tout ensemble* is decidedly picturesque; but the fabric of Sangallo was entirely abandoned after his death. (See Wood's *Letters of an Architect*.) Sangallo's greatest work is undoubtedly the Palazzo Farnese; but he must share the fame of the design with Michel Angelo, who drew the magnificent and majestic cornice which distinguishes this building from every other of the kind in Rome. The style and manner of this ancient building has been reproduced in the Reform Club-house, Pall Mall, London. Antonio Sangallo died at Terni, in the month of October 1546, leaving behind him a wide reputation of having been, according to Vasari, "a most excellent architect." (Vasari's *Lives of Painters, Sculptors, and Architects*, by Mrs Foster, vol. iv., 1851.)

SANGERHAUSEN, a town of Prussia, province of Saxony, circle and 33 miles W.N.W. of Merseburg, near the foot of the Harz Mountains, and at the lower end of the fertile valley called *Goldene Aue*. The church of St Ulrich here is said to have been founded by Louis, Landgrave of Thuringia, in 1079. According to the legend, when a prisoner in the castle of Giebichstein, near Halle, he vowed a church to the saint, if he should escape, which

he did by a bold leap into the Saale. From this feat he was known among men as Louis the Leaper. Sangerhausen has two castles, churches, hospitals, law courts, and offices. Woollen and linen cloth are manufactured, and many of the people are employed in the neighbouring copper mines. Pop. 6386.

SANGORA, a seaport-town of Siam, on the shore of a bay on the east coast of the Malay peninsula, 90 miles S.E. of Ligor; N. Lat. 7. 15., E. Long. 101. It is partly built of brick; and on the heights around it stand many pagodas, which have an imposing appearance. The town is divided into several quarters, occupied by Siamese, Chinese, and Malays respectively. The commerce of the port is chiefly carried on by vessels trading between Siam and Singapore.

SANHEDRIM, or SANHEDRIN (*Συνέδριον*, a council or assembly of persons sitting together), was the name by which the Jews called the great council of the nation, assembled in an apartment of the temple of Jerusalem to determine the most important affairs of their church and state. This council consisted of seventy senators. The room they met in was a rotunda, half of which was built without the temple, and half within; that is, one semicircle was within the compass of the temple, the other semicircle was built without, for the senators to sit in, it being unlawful for any one to sit down in the temple. The Nasi, or prince of the sanhedrim, sat upon a throne at the end of the hall, having his deputy at his right hand, and his sub-deputy at his left. The other senators were ranged in order on each side.

The rabbin pretend, that the sanhedrim has always subsisted in their nation from the time of Moses down to the destruction of the temple by the Romans. They date the establishment of it from what happened in the wilderness, some time after the people departed from Sinai, in the year of the world 2514. Moses, being discouraged by the continual murmurings of the Israelites, addressed himself to God, and desired to be relieved at least from some part of the burden of the government. Then the Lord said to him, "Gather unto me seventy men of the elders of Israel, whom thou knowest to be the elders of the people, and officers over them; and bring them unto the tabernacle of the congregation, that they may stand there with thee: And I will come down and talk with thee there; and I will take of the spirit which is upon thee, and will put it upon them; and they shall bear the burden of the people with thee, that thou bear it not thyself alone." The Lord, therefore, poured out his spirit upon these men, who began at that time to prophesy, and have not ceased ever since. The sanhedrim was composed of seventy councillors, or rather seventy-two, being six out of each tribe; and Moses, as president, made up the number to seventy-three. To prove the uninterrupted succession of the judges of the sanhedrim, there is nothing unattempted by the partisans of this opinion. They find a proof where others cannot so much as perceive any appearance or shadow of it. Grotius may be consulted in many places of his commentaries, and in his first book *De jure belli et pacis* (c. iii. art. 20), and Selden *De Synedris veterum Hebræorum*; also Calmet's *Dissertation concerning the Polity of the ancient Hebrews*, printed before his *Commentary upon the Book of Numbers*.

As to the personal qualifications of the judges of this bench, their birth was to be untainted. They were often taken from the race of the priests or Levites, or out of the number of the inferior judges, or from the lesser sanhedrim, which consisted only of twenty-three judges. They were to be skilful in the law, as well traditional as written. They were obliged to study magic, divination, fortune-telling, physic, astrology, arithmetic, and languages. The Jews say they were to know seventy tongues; that is, they were to know all the tongues, for the Hebrews acknowledged but seventy in all, and perhaps this is too

Sangora
Sanhedrim.

Sanhedrim. great a number. Eunuchs were excluded from the sanhedrim because of their cruelty, usurers, decrepid persons, players at games of chance, such as had any bodily deformities, those that had brought up pigeons to decoy others to their pigeon-houses, and those that made a gain of their fruits in the sabbatical year. Some also exclude the high priest and the king, because of their power; but others will have it that the kings always presided in the sanhedrim whilst there were any kings in Israel. Lastly, it was required that the members of the sanhedrim should be of a mature age, of a handsome person, and of considerable fortune. We speak now according to the notions of the rabbin, without pretending to warrant their opinions.

The authority of the great sanhedrim was very extensive. This council decided such causes as were brought before it by way of appeal from the inferior courts. The king, the high priest, and the prophets, were under its jurisdiction. If the king offended against the law, for example, if he married above eighteen wives, if he kept too many horses, if he hoarded up too much gold and silver, the sanhedrim had him stripped and whipped in their presence. But whipping, they say, among the Hebrews was not at all ignominious; and the king bore this correction by way of penance, and himself made choice of the person that was to exercise this discipline over him. The general affairs of the nation were also brought before the sanhedrim. The right of judging in capital cases belonged to this court, and the sentence could not be pronounced in any other place, but in the hall called *Laschat-haggazith*, or the *hall paved with stones*. Hence it came to pass, that the Jews were forced to quit this hall when the power of life and death was taken out of their hands, forty years before the destruction of their temple, and three years before the death of Jesus Christ. In the time of Moses this council was held at the door of the tabernacle of the testimony. As soon as the people were in possession of the land of promise, the sanhedrim followed the tabernacle. It was kept successively at Gilgal, at Shiloh, at Kirjath-jearim, at Nob, at Gibeon in the house of Obed-edom; and, lastly, it was settled at Jerusalem until the Babylonish captivity. During the captivity it was kept up at Babylon. After the return from Babylon, it continued at Jerusalem until the time of the Sicarii or Assassins. Then finding that these profligate wretches, whose number increased every day, sometimes escaped punishment by favour of the president or judges, it was removed to Hanoth, which were certain abodes situated, as the rabbin tell us, upon the mountain of the temple. From thence they came down into the city of Jerusalem, withdrawing themselves by degrees from the temple. Afterwards they removed to Jamia, thence to Jericho, to Uzzah, to Sepharvaim, to Bethsanim, to Sephoris, last of all to Tiberias, where they continued till the time of their utter extinction. And this is the account the Jews themselves give us of the sanhedrim.

Father Petau fixes the beginning of the sanhedrim not till Gabinius was governor of Judæa, who, according to Josephus, erected tribunals in the five principal cities of Judæa; at Jerusalem, at Gadara, at Amathus, at Jericho, and at Sephora or Sephoris, a city of Galilee. Grotius places the origin of the sanhedrim under Moses, as the rabbin do; but he makes it terminate at the beginning of Herod's reign. Basnage at first thought that the sanhedrim began under Gabinius; but afterwards he places it under Judas Maccabæus, or under his brother Jonathan. We see, in-

deed, under Jonathan Maccabæus, in the year 3860, that the senate, along with the high priest, sent an embassy to the Romans. The rabbin say, that Alexander Jannæus, king of the Jews, of the race of the Asmonæans, appeared before the sanhedrim, and claimed a right of sitting there, whether the senators would or not. Josephus informs us, that when Herod was but yet governor of Galilee, he was summoned before the senate, where he appeared. It must be therefore acknowledged that the sanhedrim was in being before the reign of Herod. It was probably in being afterwards, as we find from the Gospel, and from the Acts. Jesus Christ, in St Matthew (v. 22), distinguishes two tribunals. "Whosoever is angry with his brother without a cause shall be in danger of the judgment;" this, they say, is the tribunal of the twenty-three judges. "And whosoever shall say to his brother, Raca, shall be in danger of the council;" that is, of the great sanhedrim, which had the right of life and death, at least generally, and before this right was taken away by the Romans. Some think that the jurisdiction of the council of twenty-three extended to life and death also; but it is certain that the sanhedrim was superior to this council.

The Talmudical writers tell us, that besides the sanhedrim, properly so called, there was in every town, containing not fewer than one hundred and twenty inhabitants, a smaller sanhedrim, consisting of twenty-three members, before which lesser causes were tried, and from the decisions of which an appeal lay to the supreme council. Two such smaller councils are said to have existed at Jerusalem. It is to this class of tribunals that our Lord is supposed to allude in the passage just quoted in Matthew v. 22. Where the number of inhabitants was under one hundred and twenty, a council of three adjudicated in all civil questions. What brings insuperable doubt upon this tradition is, that Josephus, who must from his position have been intimately acquainted with all the judicial institutions of his nation, not only does not mention these smaller councils, but says that the court next below the sanhedrim was composed of seven members. Attempts have been made to reconcile the two accounts, but without success; and it seems now very generally agreed that the account of Josephus is to be preferred to that of the Mischna, and that consequently it is to the tribunal of the seven judges that our Lord applies the term *κρίσις* in the passage referred to.

The origin of the sanhedrim is involved in uncertainty; for the council of the seventy elders established by Moses was not what the Hebrews understand by the name of sanhedrim. Besides, we cannot perceive that this establishment subsisted either under Joshua, the judges, or the kings. We find nothing of it after the captivity till the time of Jonathan Maccabæus. The tribunals erected by Gabinius were very different from the sanhedrim, which was the supreme court of judicature, and fixed at Jerusalem, whereas Gabinius established five at five different cities. Lastly, it is certain that this tribunal of the judges was in being in the time of Jesus Christ. A Jewish sanhedrim is said to have been summoned by Napoleon at Paris, on July 23, 1806, and it assembled on the 20th January 1807. Compare Otho, *Lexicon Rabbinico-Philolog.* in voce; Selden, *De Synedriis Veterum Ebraiorum*, ii. 95, sq.; Reland, *Antiq.* ii. 7; Jahn, *Archæologie*, ii. 2, § 186; Parcau, *Antiq. Heb.* iii. 1, 4; Lightfoot, *Works*, plur. locis; Hartmann, *Enge Verbindung des Alten Test. mit dem Neuen*, s. 166, ff., &c.; and Milman's *History of Latin Christianity*, i.

SANITARY SCIENCE.

History.

SANITARY SCIENCE is that department of human knowledge which contemplates those laws of the human body, and of the agents by which it is surrounded, which tend to preserve life and ward off disease and death. The practical application of these laws results in the art of preserving health, which is called *hygiene*. Hygiene is sometimes defined as the art of preventing disease, in contradistinction to medicine, which is the art of curing disease. The general subject of hygiene has been treated variously by different writers. It is sometimes divided into public and private hygiene, and this is a common division amongst French writers on the subject. Public hygiene comprises the consideration of the healthy conditions and arrangements of all places in which human beings are collected together, as camps, barracks, ships, hospitals, prisons, workhouses, churches, manufactories, schoolhouses, &c. Private hygiene embraces the laws which regulate the health, life, and age of the individual. We have divided the subject of sanitary science in this article into *general* hygiene and *special* hygiene. These divisions correspond in some measure to the above; general hygiene embracing the laws which regulate the health of the human body and determine disease, whilst special hygiene embraces the application of these laws to the sanitary wants of a community and the hygienic demands of industry.

It was an early experience of mankind that certain external agencies produce disease and death, and amongst the earliest nations of antiquity certain practices were inculcated for the prevention of disease, and securing health. In the books of Moses we have a surprising instance of the care which was taken to prevent disease by the inculcation of hygienic precepts, and the adoption of sanitary laws. Although these laws and precepts were part and parcel of the great religious system under which the Jews lived, and were superintended and enforced by the priests of that religion, there can be no doubt that one great end which they secured was the health of the people. Burdensome and unnecessary as some parts of the sanitary code of Moses might be regarded in countries like our own, they nevertheless, as a whole, comprise great principles of action, which it is somewhat astonishing should have been so entirely overlooked by the modern nations of Europe, who have for centuries regarded the mission and laws of Moses as divine. In the distinction between clean and unclean beasts and birds we see those selected for food whose flesh was less likely to corrupt and putrefy, and thus to engender disease. In the forbidding the eating of blood, the most putrescible part of the animal was got rid of from the ordinary diet of the people. The regulations with regard to those who had leprosy and other cutaneous diseases were such as would prevent the spread of many of the forms of contagious disease with which we are acquainted at the present day. These precautions extended to the clothes and houses of those infected, and involve an amount of attention to the spread of infectious diseases that, if adopted with the modifications necessary for climate, and in accordance with modern science, would go far to suppress a large class of our zymotic diseases. Even the distinctive religious ordinance of circumcision seems to have had reference to sanitary requirements. In the practice inculcated of removing human excretions on to the soil, and using them as manure, we witness a procedure, and even obedience to a natural law, the neglect of which is now visiting with disease every city of Europe. The practice of burying the dead away from all human habitations, of embalming the body immediately after death, and even of burning, were all adopted by the Jews, and is indicative of the sanitary law under which those remarkable people lived.

History.

Many of these practices, however, are not exclusively Jewish, and many of the oriental nations have carried into effect similar methods of securing the health of their teeming populations. We do not, however, find any sanitary code equally explicit with that of Moses amongst the nations of antiquity, unless we except the laws of Lycurgus, under which the Spartans lived, but which were peculiar, and especially adapted to the development of the military spirit amongst this nation of warriors.

The culture of the Greeks early led to the establishment of medicine as an art in the hands of the Asclepiadæ, who gave general directions for the prevention of disease to all who resorted to their temples of health for their advice. Amongst this class of men arose the great Hippocrates, whose works must be regarded as the first attempt to reduce to law the facts on which the art of preventing disease is founded. His great treatise on *Airs, Waters, and Places* embraces a consideration of many of the questions which relate to public health, and may be read with advantage even by those who are acquainted with the facts and laws which modern science has made known. Amongst the institutions of the Greeks which seem to have had the health and strength of the community in view, we may specially refer to their gymnastic exercises, which were practised in schools especially devoted to the purpose.

Amongst Roman writers who referred to the subject of public health, we may especially refer to Celsus, whose excellent treatise on medicine contains a large number of hygienic precepts, and a philosophical perception of the importance of the subject. In the conduct of their great armies, the Romans on some points paid great attention to the rules of public health. The sites of their camps have always been regarded as examples of the care that was taken to secure localities free from the influence of injurious exhalations from the soil. They were also particular about the supply of water to their soldiers, and inculcated the practice of bathing.

The remains of Roman architecture also show that the supply of pure water to towns was regarded as essential to the welfare of their inhabitants. The practice of bathing amongst them, which undoubtedly originated in the conviction of its value in relation to public health, became converted, in the later periods of the empire, into a luxurious indulgence, to which has been traced in some measure the effeminacy which characterised the race during its decadence.

Amongst modern European nations, the subject of public health, as a branch of state action, seems to have attracted but little attention. When pestilences swept over the face of the earth, efforts were occasionally made to prevent their recurrence. The recognition and general spread of syphilitic disease in the sixteenth and seventeenth centuries led, in many countries of Europe, to legal measures for its suppression and control. Most countries in Europe adopted various quarantine regulations for the prevention of the introduction of this and other diseases. But it is said, with regard to the greater proportion of this kind of legislation, that the lack of intelligence it displayed was frequently so great as to lead to the doubt whether it did not do more harm than good.

In the conduct of the ships, camps, prisons, and hospitals in Europe, during the last century, many great and salutary improvements have been made, depending on the application of the laws of sanitary science. Previous to the time of the great circumnavigator Cook, the ships of Europe were floating lazaret-houses. The shortest voyage involved a loss of life which, at the present moment, would be regarded as frightful in the longest voyages. Captain Cook

History. claims not so much the admiration of mankind for his brilliant geographical discoveries, as their gratitude for first applying the knowledge of the laws of life to its preservation on board his ships. He first demonstrated that a ship's crew might be taken round the world without the loss of a single sailor. That curse of our navies, the scurvy, found its remedy, at the latter end of the last century, in the application of a knowledge of the dietetical necessity of fresh vegetables for its prevention. The diseases of our armies attracted the attention of medical writers to their prevention during the last century; whilst the exposure of the horrors of prisons by John Howard led to the general introduction of sanitary arrangements in their structure and discipline.

Moreover, we cannot deny to the municipalities of many of the cities of Europe an anxiety to secure, in many of their public arrangements, the health of the communities in which they lived. Many instances might be given of great works executed for the supply of water, the erection of markets, the construction of sewers, &c., with the public health in view. We owe it, however, more particularly to France that the health of the people should become a part of the care of the government. It is indeed wonderful that a subject so truly within the sphere of civil government should have been neglected so long, and that at the present no government of Europe should be able to present a consistent code of legislation on this important subject. At the latter end of the last century the Royal Society of Medicine of Paris appointed a Committee of Health, to which was referred certain subjects connected with injurious emanations from manufactories, the condition of hospitals, prisons, and other sanitary measures. In 1802 the government of France constituted a Council of Health, for the purpose of superintending sanitary operations in Paris. This council has had its numbers increased and its powers extended, and at the present day consists of eighteen members. Its function is to inquire into all matters concerning public health. It examines into the sanitary condition of markets, cemeteries, slaughter-houses, sewers, dissecting-rooms, water-closets, pumps, wells and fountains, public baths, and prisons. It prepares tables of the statistics of mortality, of the sanitary condition of workshops, &c.; and suggests remedies for the prevention of inundations, and the utilizing and deodorizing injurious industrial products. It also undertakes the suppression of medical impositions of all kinds, and the analysis of foods and drinks suspected of adulteration or injurious properties. This body has published several volumes of valuable reports, which have been edited by MM. Parent Du Chatelet and Marc. The cities of Lyons, Marseilles, Lille, Rouen, Bordeaux, and Nantes followed the example of Paris, and had their councils of public health. In 1851 a law was introduced by which the whole of France was placed under the control of the central Council of Health, with departmental coun-

cils. This plan has not hitherto produced the results hoped for, arising apparently from the too complicated nature of the machinery.

We now turn to England, where both the government and municipal bodies have been remarkably slow to recognise the importance of public measures for securing public health. There are two causes for this: first, an ignorance of the real causes of disease, and the means by which they may be prevented; and second, a religiousness of feeling which ascribes disease and death to the hand of Providence, and which leads to the impression, that human efforts are unavailing against these decreed visitations of the hand of God. It was not until the year 1831, when the cholera visited this country, that the public mind became awakened to the fact, that much of its destructive effect was the result of circumstances which could have been prevented by human foresight; and that such pestilences could only be avoided in future by greater attention to the conditions by which the life of the community is regulated. It is to the writings and labours more especially of Dr Southwood Smith that we are indebted to the sanitary legislation which commenced in this country after the first alarming outbreak of cholera in 1831. It was not, however, till the history of this disease pointed to the probability of its recurring again in this country that legislation commenced. In the year 1845 the "Nuisances Removal Act" was passed. This was, however, only a temporary measure, and intended to meet the exigencies of an immediate outbreak of cholera. This disease did not reach England till 1848, and then the Nuisances Removal Act became permanent. This act, although very defective, acknowledged the right of the magistrate to interfere in all cases where the circumstances of property or individuals, either alone or combined, led to the development of conditions which could produce disease. It awakened the public mind to the fact, that there existed in all our large towns preventible causes of disease; and much sanitary activity was the result.

Between the temporary and permanent passing of the Nuisances Removal Act, an act of great importance, in a sanitary point of view, was passed, and this was the Baths and Wash-houses Act. By this act vestries and local boards were empowered to erect baths and wash-houses, and to obtain funds for this purpose from public rates and funds. The poor were by this means supplied with one of the greatest necessities of our large towns,—water for washing purposes at a rate which enabled them to use it as extensively as their circumstances required. Upwards of twenty institutions of this kind have been established in London. The following table, drawn up for the use of the vestry of St James's, Westminster, will give an idea of the extent to which these institutions have been employed, and the sums received for their use:—

Table showing the Bathing and Washing at the Establishments in London, which are conducted under or in accordance with the Acts 9 and 10 Vict., cap. 74, and 10 and 11 Vict., cap 61, for the Year 1858.

History.

History.

We may notice that the general conviction of the necessity of sanitary measures increased, and led to the introduction of powers for making provision for public health into acts which otherwise might have passed without these provisions. Among the Consolidation Acts of 1847 was the Towns Improvement Clauses Act, many of the provisions of which have since been embodied in other acts, and which contain a variety of clauses relating to the sanitary question. The great act, however, which forms the most distinguishing feature of the sanitary legislation of England, was the Public Health Act, which was passed in 1848. By this act a General Board of Health was constituted, at the head of which was a president appointed by the government. Under this act power was given to local authorities to construct public works of various kinds, but more especially for improving the drainage and water supply. Since the passing of this act, 236 towns have placed themselves under its provisions. These towns contain populations varying from 500 to 200,000. These are exclusive of places which have put in force various sanitary regulations under powers given them by local acts. The expenditure upon the works thus executed has been calculated to be not less than L.3,500,000. Although this statement shows that a vast amount of sanitary activity has been called forth by the public health, it nevertheless gives but an imperfect idea of the indirect benefits which have resulted by the fixing public attention on the importance of the prevention of disease and death. The diminution of the mortality consequent upon the introduction of sanitary improvements in some of the towns of England will be seen from the following table :—

Names of Towns.	Death Rate in 1000		Number of of lives saved in 1000 per annum.

St Thoma.	26.9	23.0	3.9

It must not, however, be supposed that anything like a perfect system of public sanitary exertion exists even in the improved towns; and a large number of small towns and villages exist where the prevalence of fever and the high mortality indicates that little or nothing has been done for the improvement of the public health.

After ten years of successful operation, the Public Health Act was repealed in 1858, and the General Board of Health abolished. This arose partly from the nature of its operations being misunderstood, and partly from the activity of the board offending those who wished things to remain as they were, or wished to act for themselves. The Board of Health was really a board of works; and as they repudiated interfering actively in matters relating exclusively to hygienic arrangements, the name misled. The powers, however, granted under this act are still continued by the operation of the Local Government Act, and are still to be exercised by local bodies, and no cessation of the benefits of previous legislation is contemplated.

It was, however, considered necessary to give to some central body power to act in cases where disease reached a certain amount of fatality, or where fevers or other conta-

History.

gious diseases broke out with great violence; and a new "Public Health Act" was passed in 1858, which placed this power in the hands of the Privy Council. To this office is now given the power possessed by the General Board of Health under the act of 1848 and subsequent acts. This act, which was originally passed for one year, was made permanent in 1859.

Besides this great sanitary act, other measures have passed through the legislature which demand notice here. The Common Lodging-Houses Acts were passed in 1851 and 1853. Under the Public Health Act powers were given to local boards of health to register houses which were let out as common lodgings, and to inspect them, and regulate the number of their inhabitants. These powers soon brought to light the existence of a state of filthiness, indecency, and iniquity that led at once to the passing of the strongest possible measures for suppressing such sources of disease and moral degradation. Of the two measures referred to, one relates to the regulation of common lodging-houses, and the other is a permissive act, to enable public authorities to erect common lodging-houses. Under the first act, the commissioners of police in towns, and the justices of the peace in the country, have the power of regulating these places. The good that has been effected under this act has been very considerable in London and many large towns, although it is to be feared that not sufficient attention has yet been given to the overcrowding of private lodging-houses as the result of the supervision of the common or nightly lodging-houses.¹ Some idea may be formed of the magnitude of the evil which the act was intended to counteract, when it is known that upwards of 100,000 people were lodged in the common nightly lodging-houses of London when the police first entered upon their duties under this act. This act has only been enforced in a few towns in the country; but where it has been put in force, it has been shown that, in proportion to their population, many of the towns of England are quite as bad as London. It is, however, an acknowledged fact, that wherever this act has been put in force, a great and manifest improvement has taken place in the character of the population affected by the provisions of this act.

The object of the second act, The Labouring Classes Lodging-Houses Act, was to encourage the building and establishment of lodging-houses properly constructed and carried on for the accommodation of the working-classes. This act was intended to supply decent and proper accommodation for those who were displaced by the provisions of the first act. At present, however, the local authorities have not availed themselves of the provisions of this act, except in a very few instances. It is to be hoped that this will not long be the case, and that when it comes to be better understood how much more expensive to the community are dirt, squalor, and moral degradation, than cleanliness, health, and morality, that the provisions of this act will be extensively put in force.

The next sanitary acts in point of date are those relating to the burial of the dead. In 1851 and 1852 acts were passed, the object of which was to prevent the burial of the dead in churches and chapels, and in burial-grounds surrounded by a dense population. The Metropolitan Interments Act, which not only interdicted interment in London, but provided a complicated system for the removal of the dead, and their burial in a large cemetery in the neighbourhood of London, was never carried into effect. But the evils of burying the dead in the midst of the living had become so notorious, and the practices of extortion on the

¹ In the city of London the powers given to the Commissioners of Sewers for the regulation of common and nightly lodging-houses are very extensive; for by the Sewers Acts of 1848 and 1851, the commissioners have control over all houses occupied by more than one family, any room of which is let for less than 3s. 6d. per week. This, indeed, is the definition of a common lodging-house in the City Acts of Parliament.

History. part of those who undertook the management of funerals, that the Burial Act, simply forbidding the burial in towns and places of worship, has led to the most extensive reforms. Within the last ten years upwards of ten new cemeteries have been opened in the neighbourhood of London; and in almost every large town in the country similar provision has been made for the interment of the dead.

Amongst the individual sanitary evils against which the sanitary legislation of England has been directed is that of smoke. It is well known that smoke is composed of unconsumed particles of carbon, which, entering the atmosphere, fall down again, producing great uncleanness, and leading to a practice of closing doors and windows, to the injury of health. Power was given to local bodies to diminish this evil in large towns under the Towns Improvement Clauses Consolidation Act. In some towns this power has been taken advantage of, whilst in others the principal manufacturers and producers of smoke have adopted the practical methods suggested for abating this nuisance. In 1813 a special act was passed, under the title of the Smoke Nuisance Abatement Act, in which powers were given to magistrates to fine those whose manufactories were complained of as producing smoke amounting to a nuisance. The application of this act to London has been attended with an immense improvement, although the smoke generated in private houses still produces a comparatively impure and murky atmosphere. Under the Local Government Act, it is competent for the local authorities in any town to introduce the Smoke Nuisance Abatement Act. A general introduction of this act, and the extension of its powers to the construction of fireplaces in private dwellings and workshops in towns, would be undoubtedly attended with increased cleanliness, and a greater attention to the ventilation of houses.

In 1855 the Nuisances Removal Acts of 1845 and 1848 were repealed, and the Nuisances Removal and Diseases Prevention Act was passed. This act, which is now in force, gives a legal definition of nuisances, which is as follows:—"Any premises in such a state as to be a nuisance or injurious to health." "Any pool, ditch, gutter, water-course, privy, urinal cesspool, drain, or ashpit, so foul as to be a nuisance or injurious to health." "Any animal so kept as to be a nuisance or injurious to health." "Any accumulation or deposit which is a nuisance or injurious to health."

By means of these stringent definitions, a variety of causes of diseases are brought within the operation of the law. The local authorities can give notices for the removal of any nuisance; and if this is not attended to, a summons can be issued, and the offending parties brought before a magistrate. In certain cases also, where works are necessary to be done, the local bodies can do the work, and charge the person on whose premises the nuisance has existed. The duties of a medical officer of health and of a sanitary officer are also recognised; and these officers have power given them to inspect premises in cases where they suspect a nuisance to exist. The medical officers of health and sanitary inspectors have also powers given them under this act to inspect all articles of food exposed for sale which are suspected to be unfit for use as human food, and to seize the same, and bring the offender before the magistrate, who has power to inflict a fine upon the owner of the provisions thus seized.

A clause also, in the same act, gives power to the sanitary officers to inspect the premises of persons carrying on offensive and noxious trades, and to point out the best means of preventing any injurious influence being exercised upon the neighbourhood, and of appealing to the magistrate if their suggestions are not carried into effect.

A clause in this act goes so far to avert the evils which

History. might arise from the operation of the Common Lodging-House Act, in driving people to private houses for their nightly lodging, as it regards the overcrowding of dwelling-rooms as a nuisance. In many parts of London, any room not allowing a space of 400 cubic feet to each individual habitually residing or sleeping in it is regarded as a nuisance, and brought under the operation of this act.

This act also contemplates the suppression of the unhealthy practice of dwelling in cellars or kitchens, and defines the conditions on which any room under the ground shall be allowed to be let as a residence. This act, though occasionally found too slow in its operations to remove an immediate and pressing cause of disease, has been found one of the most effectual of the various measures of English sanitary legislation for the permanent improvement of the health of towns. When it is considered that it deals with all those small causes of disease which are so constantly occurring in a civilized community, it is wonderful that its provisions are not more generally enforced. In any town or country district it would only be an act of benevolence on the part of the clergyman, the magistrate, the lawyer, or the medical man, to insist on its provisions being carried out in all cases where the manifest causes of disease exist.

Comprehensive and sufficient as the preceding legislative measures may appear to be, they are not based upon any comprehensive principle, and are deficient of any common basis of action. There are consequently constantly arising cases which require special legislation. London is an instance of this. The entire management of the sanitary condition of the city is confided to the corporation, whose acts date back to 1848; but as the city includes not more than a twentieth part of the metropolis, the health of the surrounding population had to be cared for in very various ways. It is not necessary here to enter into any account of the sanitary measures adopted in the metropolis under the various local boards and vestries. It will be sufficient to allude to the fact, that the city of London possesses local sanitary powers, which were put in force, under the control of a medical officer of health and sanitary inspectors, several years before the rest of London.

In 1857 the Metropolis Local Management Act was passed, which gave to all the parishes of London, with the exception of the City, the power of action in relation to sanitary matters. The management of the sewers, and various other powers in relation to the general condition of the metropolis, was vested in a metropolitan board of works, whose members were elected by the various vestries or local boards to whom the parochial management was confided. To the vestries or local boards are given powers to enforce all regulations connected with sanitary matters. One of the most important provisions of this act is the appointment of medical officers of health. Each vestry or board is required to appoint a duly-qualified medical man to fill this office. It is his duty to direct the operations of an inspector or inspectors of nuisances, who visit houses, workshops, manufactories, and other places where nuisances are either reported or suspected to exist. He sees to the ventilation of public buildings,—as churches, chapels, theatres, courts of law,—and obtains the sanction of the local board for all proceedings connected with the removal of nuisances. He receives from the registrar-general the weekly report of births and deaths in his parish; and by the latter he is guided to the existence of disease in his locality, which may require on that account special attention. The improvement that has taken place in London under the powers of this act has been very great; and the amount of negligence, with regard to the sources of disease, that has thus been revealed, is perfectly astonishing. At the same time, the local boards are not yet alive to the immense advantages to be derived from carrying out the provisions of

History. this act. In many instances the medical officer of health meets with no encouragement in the performance of his duties, and no regular system of inspection is prescribed to the inspectors of nuisances.

In this bill, no provision was made for dealing with the sanitary condition of the Thames. This great river, like other rivers flowing through towns, had been used from time immemorial as a receptacle for the refuse of the inhabitants on its banks. Moved by the daily access of the tide from the sea, and receiving upwards of 100 millions of gallons of water daily, for centuries the refuse poured into it produced little effect upon its purity. It was not till the extensive introduction of the water-closet system in London, and the abolition of cess-pools, with also the increase of gas and other manufactories on its banks, that the river began to give indications that it was receiving a larger quantity of decomposing matter than it could purify, or get rid of by its tidal movements. In 1856 it became apparent in the summer months that the river emitted a disagreeable stench. This became still more evident in 1857, and was obviously dependent on increased attention paid to the removal of all refuse from houses by the aid of drainage. In 1858 the stench again appeared with increased intensity, and was especially nauseous in the neighbourhood of the new houses of Parliament. Every one felt that special legislation was necessary to meet so gigantic an evil. This great river had become an elongated cess-pool, and the effect upon the teeming population of its banks might be, in the course of a short time, of the most disastrous kind. Accordingly, an act was passed in 1858, giving power to the Metropolitan Board of Works to commence works for the main drainage of the metropolis, and for preventing, as far as practicable, the sewage from passing into the Thames within the metropolis. It also gives them power to construct works on the shores and bed of the Thames; and empowers them to borrow for these purposes a sum of money not exceeding three millions. The works thus sanctioned are now in the progress of construction, and comprehend the complete drainage of an area of 117 square miles, and of houses calculated for the residence of a population of 3,500,000 people. These works are intended to carry separately the sewage of London down to a point of the Thames so far below the metropolis as not to interfere with the health or comfort of its inhabitants. The questions of deodorizing the sewage, or utilizing it, are purposely left open for the present. This improvement of the condition of the river will necessarily be followed by other arrangements. One of these is the embankment of the Thames, by which the scour of the river will be increased through London, a very necessary plan when it is remembered that 80,000,000 of gallons of sewage, which is now poured into the Thames above Blackwall, will be emptied into it at a much lower point. In connection with the completion of the system of main drainage, a plan has been proposed by Captain Fowke, by which any regurgitation of the sewage into the Thames passing through London would be effectually prevented. This consists in throwing a weir over the Thames below Greenwich, and cutting a canal with locks through the Isle of Dogs, so as to enable the traffic above the river to be carried on. This would relieve London of all difficulties from the tide, and give it a river of pure water, constantly at high-tide mark. If such a plan is not really open to objection, it would restore to London the river in more than its ancient purity, and which for bathing purposes and aquatic amusements would contribute greatly to the health of the metropolis.

Before closing this sketch of the sanitary legislation of

England, we would refer to some of the minor acts which have been passed on subjects involving the public health.

History.

From the time of the first discovery of vaccination as a means of preventing small-pox, enactments have been passed to secure the extension of the practice of vaccination. Obvious as is the benefit to be derived from this practice it has been greatly neglected, and recently a Vaccination Extension Act has been passed. By this act, all persons are required to have their children vaccinated within three months of their birth, under a penalty of ten pounds for neglect. It is, nevertheless, found that large numbers of persons allow their children to grow up without vaccination; and the result is, that there is always a fraction of the people susceptible of the ravages of this disease, and sufficient to keep it always smouldering and ready to break forth into a flame in all our city populations.

The slaughtering of animals in private houses, where there exists little or no proper accommodation, has always been regarded as a great nuisance, and an act has been passed for the better regulation of slaughter-houses, by which the local magistracy have power to refuse a licence to persons slaughtering on their own premises. Although under this act licenses have been refused by the magistrates, yet, such is its deficiency, that it is well known in London that slaughtering takes place extensively without the granting of any license. It is hoped, however, that this act will lead local authorities to see the propriety of erecting abattoirs, or public slaughter-houses, for the accommodation of butchers, in which neither the food thus prepared nor the population of the neighbourhood will be in any way injured.

There are many other measures which have been adopted from time to time with a sanitary object in view; such as the introduction of lemon-juice into the navy as a preventive of scurvy, and the requiring the captains of merchant ships undertaking voyages of a certain length to have this article of diet on board for the use of the sailors. Since the revelations made by the Crimean war of the utter deficiency of all our military arrangements to secure the proper health of our soldiers, the whole subject of the sanitary condition of the army has been inquired into by a commission appointed by Parliament, whose report has revealed a deficiency of sanitary arrangements in our barracks, and in the management of our soldiers, that could be equalled only in the most neglected and miserable parts of the population of our large towns. The same evils have been found to exist in our Indian army, and amongst the regiments in our colonies. Almost all arrangements, whether of food, clothing, or shelter, have been found to have been made in ignorance of vital laws, and in defiance of the experience of civilians.

In this brief sketch of English legislation in relation to sanitary science it will be seen that, although much has been done, much more remains to be done. The subject of public health has been treated piecemeal, and no general organization for sanitary purposes exists. The subject, though one lying at the very foundation of human society, has not attracted public attention to the extent which its importance demands. Neither the legislator nor the lawyer, the magistrate nor the medical man, are instructed in the principles of sanitary science. Although professorships of hygiene exist in the universities of the Continent, no public recognition of this subject as a branch of education has taken place in Great Britain. It is still an object worthy the attention of our legislature, to place sanitary science in such a position that it may confer on the community all the advantages which a knowledge of its principles, and their practical application in daily life, is calculated to confer.

General
Hygiene.

PART I.—GENERAL HYGIENE.

The department of general hygiene embraces a knowledge of the laws which regulate the existence of the human being, and may be divided into three sections: *first*, the consideration of individual differences and peculiarities; *second*, of those external agents and internal functions on which the life of the individual depends; and *third*, the influence of especial morbid agents, as the poisons of infectious and contagious diseases.

1. INDIVIDUAL PECULIARITY.

When mankind is regarded as a whole, we find that the external agents by which man is surrounded act very differently on different groups of the human family; and on a closer investigation of the causes of this difference, we find it can be referred to individual peculiarity. In any application of hygienic rules, it is of the utmost importance to keep these peculiarities and differences in view. The conditions which would ensure the health of the Englishman are not applicable to the Esquimaux or the Hindu; and the varying temperaments, ages, idiosyncrasies, hereditary tendencies, habits, and constitutions of individuals must always be considered.

Race.—The question of whether the races of men have been produced as the result of circumstances, or whether they have been born with their peculiarities stamped upon them, is still perhaps an open one with ethnologists; but for the hygienist the great fact is evident, that there are different races of men, on whom external agents act very differently. This is a question of considerable importance, and has not hitherto obtained the attention to which it is entitled. The races inhabiting the central and northern parts of Europe will not bear the heat of tropical climates with the same impunity as the Asiatic and African races, born and nurtured within the tropics; whilst the inhabitants of these countries require much warmer clothing for their health when in the temperate or colder regions of the earth than the natives of the same districts. How far this is connected with the special susceptibilities of particular tribes is a matter of highly interesting inquiry.

Temperament.—Next to race, we may reckon the influence of what is called temperament. Three well-marked forms of temperament have been recognised by all medical and physiological writers. These are respectively called the nervous, the sanguine, and the lymphatic. To these some add a bilious or melancholic temperament; whilst medical writers recognise diatheses as the scrofulous and rheumatic. At any rate, persons with the distinguishing features of these temperaments exhibit very different tendencies with respect to disease. The circumstances that would quickly produce special forms of disease in one class will not affect another at all. Thus, taking the two latter conditions of the system, the scrofulous and rheumatic, as examples, it is found that a variety of circumstances will produce an outbreak of scrofula or rheumatism in these two general conditions of the system which will not in those conditions of the system where their signs are not present. In the application, then, of hygienic rules, it should always be remembered that what will produce disease in persons of one temperament will not in another. And, again, the same cause may in two persons of different temperaments produce different kinds of disease.

Idiosyncrasy.—Persons of all temperaments may have peculiar relations to external circumstances. Thus, where the tendency is to the production of the same disease under the same circumstances, it is called an idiosyncrasy. Some persons faint at the sight of blood. Others vomit under peculiar odours. Some contract febrile disorders wherever exposed to their special contagions. These cases

require consideration in the application of hygienic rules, and care should be taken not to draw a general inference from the experience of individuals thus constituted.

Age.—This is a most important element in all hygienic considerations. The infant is much more susceptible of injurious agencies than the youth or the adult. Nearly half the population of our large towns dies before it is five years old. This death is, however, unnatural. Much of it might be prevented by a knowledge on the part of the community of the laws which regulate the life of children, as compared with that of adults. Children are improperly fed, nursed, housed, and clothed; and the consequence is, they die. They require different food from adults; they are more susceptible of cold, of the action of poisons, and of a variety of morbid agencies; and until greater attention is paid to their special relations to external agencies, the sad tale of our annual bills of mortality will be told. The injurious effect of this mortality is not limited to the destruction of life. Where one child dies, ten are taken ill from the same causes, and recover. The cost of illness is thus added to that of death. But the evil does not end here. Half of the life thus lost is lost before it is twelve months old. The mother, instead of healthfully nursing her offspring, becomes again pregnant; and in this way a permanent effect is produced on the age of the whole population, as those who struggle through become a younger population than if their elder brothers and sisters had lived. Where the mortality amongst children is greatest, there the average age of the population is least. This reduces the working power of a population, and renders it less able to enter upon those occupations by which food is produced, money realized, and wealth accumulated.

What is true of infancy is also true to a limited extent of childhood and youth. In the period from three to fifteen and twenty years of age, young persons are not able to resist the causes of disease so well as those who are older. The young men in our armies suffer more than the middle-aged from exposure and fatigue.

Whilst the young from twenty to the middle age at forty-five are best able to resist the external causes of disease, it should be remembered that the poison of typhus and typhoid fevers seems to act more vigorously on those of middle age than at any other period of life.

The peculiarities of old age are almost as marked as those of infancy. Diseases of deficient or decayed nutrition come on; and the circumstances of the aged require especial consideration in the adaptation of hygienic rules.

In the special applications of the laws of sanitary science to the prevention of disease, *sex*, *hereditary tendencies*, *acquired habits*, and *morbid dispositions*, must always enter into consideration.

2. AGENTS INFLUENCING LIFE.

(A.) *External Agents.*

The distinction between external agents which influence life, and the organs by which the functions of life are performed, is not easily made. When we examine a vegetable or animal body, with a view to ascertain the nature of its vital processes, it is difficult to say where the chemical and physical forces end, and the vital ones commence. For practical purposes, however, we may speak of certain chemical and physical agencies as external to the human body, as the air, the soil, and water; and of certain others as acting more intimately on the organs of the body, and undergoing changes in them as internal agencies, as the food from which is formed the blood, and of the secretions which are got rid of from the blood by the aid of the various glands of the body. It is obvious that the consideration of these subjects belongs to physiology; and all that the writer on hygiene has to do is to point out the

General
Hygiene.

General Hygiene. practical bearing of these subjects on the preservation of health.

Light.—Of the great forces which are continually in action in nature, light is one of the most important. By its chemical action on the vegetable cell, it converts the elements of carbonic acid and ammonia into the various compounds which form the great variety of vegetable products, and more especially those which yield food to man and the animal kingdom. In proportion as light is withdrawn, vegetation dwindles; and as light acts, it is profusely developed. This is seen as we proceed from the poles to the equator on the surface of the earth. The direct action of light on man and animals has not been so well ascertained. There can be no doubt, however, that light exercises a favourable action on human health. We may, indeed, infer that, to a limited extent, the same changes go on in certain of the animal tissues which are so characteristic of the vegetable, and that these may contribute to the healthy development of the organs of the body. No definite conclusions can be arrived at from the experience of those who live in mines and caverns, away from the light of day, as so many other unhealthy circumstances prevail in such places. But of the cheerful influence of light on the mind there can be no doubt; and in all cases as much light should be admitted into buildings as should enable persons to feel its exhilarating influence.

Heat.—This force, which in a large number of instances is co-existent with light, exerts a powerful influence on vegetation, but is still more remarkable in its effects on animals and man. Without heat, light would not act beneficially on plants. Without certain degrees of heat, animals and man cannot exist. The tissues of most plants are destroyed at a temperature below 32° Fahr.; and although the germs of both plants and animals will for a certain time resist a temperature much below this, no growth takes place at such temperature. The vegetable world disappears as it were as the temperature passes from below 60° to the freezing-point. This also is the case with the great mass of the lower animals. But in the higher animals, provision is made for the maintenance of their temperature independent of that of the atmosphere. Thus man, under all circumstances, has a temperature of 98°. It is the due maintenance of this temperature that makes his relation to external heat an object of hygienic rules. If the external temperature is low, then the object must be to prevent such an amount of diminution of the internal heat as would lead to disease. This is done in two ways: first, by increasing the heat-producing food which is daily consumed; and second, by diminishing the loss of heat from the surface by warm clothing or the production of an artificially-warmed atmosphere. It is not often that the external temperature rises to the height of that of the body; but in proportion as it rises above 60° or 65° an impression of warmth is produced on the body, and the necessity for cooling processes is produced. Clothing needs to be reduced in quantity; a moving atmosphere must be substituted for an artificially-warmed one; and as the heat increases, the application of cold to the surface should be had recourse to. This latter object is best effected by means of cold bathing.

Electricity.—The electrical force is frequently disturbed in the atmosphere and on the surface of the earth. Plants and animals partake of this disturbance, and in the case of the manifestation of free electricity, present the usual signs of positive or negative electricity. Although many elaborate efforts have been made to connect morbid tendencies, diseases, and even the outbreak of epidemic diseases, to the action of electricity, at present the evidence is wanting to show that any condition of terrestrial electricity acts as a cause of general disease. In those states of the atmosphere where electricity is developed, other phenomena are generally present, to which may be ascribed the effects

usually attributed to electricity. It is sufficient to say here, that at present we know little or nothing of the agency of electricity in the production of disease. The only subject in connection with electricity which demands attention on the ground of public safety is that of preserving life and property from destruction by the aid of lightning-conductors.

The Atmosphere.—The great aerial ocean which surrounds the world is necessary to the existence of both animals and plants. It is subject to considerable chemical and physical variations, which affect more or less the health of man. It is also the medium for the diffusion of those poisons which, either arising from decomposing animal or vegetable matter, or the diseased body of man, produce those forms of zymotic disease which are most destructive of human life.

Atmospheric air consists principally of oxygen and nitrogen; with these are mixed aqueous vapour and carbonic acid. Of these constituents, oxygen is the most important, as by its agency many of the functions of animal life are carried on. The oxygen unites with the carbon of the food in the blood of animals, and the result is the formation of carbonic acid and the evolution of heat. Where atmospheres have their composition altered by artificial means, as in overcrowded rooms, the reduction of the quantity of oxygen acts injuriously on the system, by diminishing the oxidating processes which are going on in the system.

Oxygen assumes two forms in the atmosphere, one of which is called ozone. This latter form, of ozone, is not always present, but is sometimes very abundant. Ozone is a more active form of oxygen gas. It readily unites with the combustible elements, and appears to be the great agent for reducing those compounds arising from decomposing vegetable and animal matters in the air which would otherwise be injurious to health. In the same way, it acts beneficially on the human system, by quickening those processes of oxidation which are essential to health.

Ozone is tested for by the property it possesses of decomposing iodide of potassium, uniting with the potassium and setting free the iodine, the presence of which may be detected by the agency of starch. Thus, test-papers saturated with a solution of iodide of potassium and starch are employed to denote the presence of ozone. Ozone is found abundantly in air coming from the ocean, and in mountainous and rural districts free from vegetable and animal decomposition. It is seldom found in the air of London or our large towns. When found, it is in the suburbs, and when the wind is blowing from the sea or the country towards the city. The consideration of the presence and agency of ozone is one demanding further consideration.

The quantity of moisture contained in the atmosphere varies, and exercises an important influence on the functions of life. The quantity of moisture that can be taken up into the atmosphere depends upon the temperature. As a rule, the higher the temperature the larger the quantity of moisture. At the same time, the quantity of moisture in the atmosphere varies with a number of circumstances, as the time of the day and the year, height above the sea-level, prevailing winds, &c. The quantity of moisture in the air affects considerably the transpiration of water from the human body through the skin and lungs. When the atmosphere is moist, the rapidity with which transpiration is performed in the human body is much less than in a dry atmosphere.

The quantity of moisture in the atmosphere differs much in different places; and it becomes frequently a matter of practical importance, in the location of houses, for families to ascertain what is the prevailing amount of moisture in the atmosphere. There is abundant evidence to show that an excess of moisture in the atmosphere above the average is injurious to health. It diminishes the changes which go

General Hygiene.

General
Hygiene.

on in the body, and leads to diseases of low vitality. On the other hand, a very dry atmosphere is found to stimulate the action of the skin and lungs, and to bring with it a train of disorders, which are removed or relieved by a change to a humid atmosphere.

The influence of heat and moisture combined requires consideration; a moist atmosphere with a low temperature produces different effects from a moist atmosphere with a high heat. The latter conditions are especially productive of disease amongst the European nations, whilst the former conditions are destructive of the life of those races of people who live in tropical climates.

In England the hottest months of the year are the most unhealthy, and this unhealthiness is increased if the atmosphere is unusually moist. The next most unhealthy portion of the year is the cold months; and the public health suffers more if an unusually moist atmosphere prevails.

The carbonic acid naturally contained in the atmosphere is the result of the oxidating processes that go on on the earth's surface, as the respiration of animals, the decomposition of dead animal and vegetable tissues, the combustion of carbon, and the evolution of gases from springs and volcanoes in the bowels of the earth. In this quantity it is the food of plants, and is perfectly uninjurious to man and the animal kingdom. This gas, however, is constantly liable to increase in the atmosphere, when the products of combustion or respiration are prevented from finding their way into the great bulk of the air. This is the case in houses and places of public assemblage, rendering ventilation necessary. The evidence of the injurious effects of an increased quantity of carbonic acid in the atmosphere is very decisive. Not only have we proof that life may be destroyed by its presence, as in the case of the prisoners in the Black Hole of Calcutta, but also proof that an atmosphere vitiated with it to an extent in which no immediate injurious effects are produced will produce the most destructive effects on the system. A large amount of scrofula and phthisis is dependent simply on the depressing agency of this gas in sleeping and other apartments, where people spend a great portion of their lives. A great social sanitary work has yet to be done, in calling the attention of the public to the danger of living in rooms in which the carbonic acid from respiration and combustion is not freely got rid of.

The pressure of the atmosphere exercises an influence on the life and health of man. The dwellers in valleys, or in districts on a level with the sea, experience a greater amount of atmospheric pressure than those who live on hills and mountains, or at heights above the level of the sea. The pressure of the atmosphere differs also in the same place, and at different seasons of the year and times of the day. It has been observed that epidemic and pestilential diseases are connected with an unusually dense condition of the atmosphere. During the prevalence of cholera in this country in 1832, in 1849, and 1854, the barometer indicated the highest amount of pressure in the atmosphere during the period.

A diminution in the pressure of the atmosphere is attended with congestion of the capillaries, and copious perspiration and apoplectic seizures; and sudden deaths occur as the result of this condition of the capillary circulation.

A rapid movement of the atmosphere is attended with a diminution of its pressure. In this way, winds act mechanically on the health.

Winds also act on the health according to the direction in which they blow. They are hot and cold, moist and dry. In this country they exercise a very marked influence on health and life. The north is dry and cold, and prevails in the middle of winter. Wet northerly winds give rise to diarrhoea and disturbance of the digestive organs. The north-east wind is cold, and sharp, and dry. It is attended

General
Hygiene.

with little moisture in the atmosphere, and accompanies the driest weather. The east wind is dry and cold. The prevalence of these winds produces great fatality amongst phthisical patients. They are accompanied with a peculiar form of dyspepsia, which tends to develop rheumatism and gout. The east wind seldom gives any indications of the presence of ozone.

The south-east wind is a moist and cold wind, and is almost invariably accompanied with rain in this climate. It contains a considerable amount of ozone. Diarrhoea, cholera, cynanche, dysentery, and bronchitis prevail with this wind.

The south wind is generally accompanied with rain and an elevated temperature. It affords the greatest quantity of ozone; and although highly favourable to the longevity of phthisical persons, produces catarrhs and bronchitis.

The south-west, west, and north-west winds are all more or less favourable to health. They come to this country more or less charged with the pure air of the Atlantic; and although accompanied with rains and storms, do not appear to act injuriously on man.

It will be seen that it is an important thing, in fixing on the localities of towns and houses, to regard protection from prevailing winds. In other parts of the world particular winds prevail, as the *simoom* and the *sirocco*, whose effects on life and health are very destructive.

An absence of wind is a state of the atmosphere in which the greatest pressure of the barometer is likely to occur, and in which the influence of corrupting and putrefying agents in the atmosphere is most likely to be felt. During the prevalence and preceding the breaking out of great epidemics, unusual stillness of the atmosphere has prevailed. This was observed in the great plague of London in 1665, and also during the prevalence of the three great cholera epidemics in England.

The atmosphere also requires study from the sanitarian, on account of its being the medium through which poisons are frequently introduced to the human body. Mineral particles of all kinds may be conveyed through the air. Thus, in trades producing dense powders, such substances are conveyed through the air, and introduced into the lungs, thus becoming sources of disease; as in the steel-dust of the knife-grinder, the coal-dust of the miner, &c. The fumes of mercury, phosphorus, sulphur, arsenic, and other substances used in the arts, are thus conveyed to the artisan; so also injurious gases, as sulphuretted hydrogen, carbonic acid, carbonic oxide, &c. It is the law of vegetable and animal compounds that their elements shall return to their simpler compounds by putrescence and decay. The elements thus combining and forming compounds which escape into the atmosphere are carbon, hydrogen, nitrogen, oxygen, sulphur, and phosphorus. Many of the gases thus formed are very injurious to human health. The form, however, in which animal and vegetable matters appear to be most injurious in the atmosphere is that of a tendency to change before the ultimate compounds are formed. In this state vegetable and animal matter is capable of establishing in living bodies states of change in their tissues similar to that in which they themselves are. These bodies thus act as ferments. In some states of the atmosphere these substances, of whatever nature they may be, are much more readily conveyed than in others. As a rule, hot, moist, and still conditions of the atmosphere favour the conveyance of these particles of matter. Hence it is, when all these conditions combine, that zymotic diseases prevail most.

Water.—In the form of vapour, water has most important relations to life, as we have seen in the preceding section; but in the condition of liquid water it sustains other relations of equal importance. Water is necessary to man as a civilized being, but naturally he uses it for cleaning and

General
Hygiene.

washing, and takes it internally with his food. In all these relations it is of great importance that the water he uses should be free from impurities which are likely to engender disease. The first great source of water is the ocean, which being carried into the air in the form of vapour, is again precipitated on the earth in the form of snow, or rain, or dew. The water that falls on the earth is, part of it, carried off in the form of rivers back to the sea and another portion enters the earth, and comes again to the surface in the form of springs. Thus we have naturally sea-water, river-water, and spring-water. The latter is constantly impregnated with mineral constituents; and when these are very obvious, the waters are called mineral. If the water comes to the surface of the earth with a greater heat than natural, it is called thermal. Sea-water is unfitted for dietetical purposes, on account of the large quantity of salt it contains. This does not, however, prevent its being used for the purpose of bathing, in which the object is the application of cold to the skin. The exercise of swimming is more easily performed in salt than fresh water, and the stimulant effect of the salt appears to exercise a healthy influence on the capillary circulation. In cases where it is desirable, it should be known that pure water can be obtained from the distillation of sea-water.

River and spring waters are those which are mostly employed for washing and dietetical purposes. These waters seldom contain so large a quantity of saline matter as sea-water. The saline matters may, however, be in quantities to render them unfitted for either washing or drinking. Where the saline constituents interfere with the action of soap, they are objectionable for washing purposes. When the saline constituents are similar to those found in the blood, they do not appear to exercise an injurious influence for dietetical purposes, unless they are in great excess.

All waters are liable to contamination, from the presence of decomposing animal and vegetable matters. The existence of large bodies of water containing such matters is frequently prejudicial to health. Lakes, ponds, bogs, and stagnant waters generally, are liable to this contamination, and the effluvia they give off produce diseases of various kinds, more especially intermittent and remittent fevers. Rivers into which the refuse of towns is poured are liable to this contamination, and are thus not only rendered injurious for drinking purposes, but detrimental to those who live on their banks.

Spring or well waters are exposed to these contaminations. In towns, where the soil is permeated with the contents of cesspools or the leakage of drains, the wells may be contaminated, and the water thus rendered entirely unfit for use. Extensive evidence has been brought forward to show that attacks of epidemic cholera have been connected with the contamination of well and river waters used for dietetical purposes. Such waters may be rendered comparatively sweet by boiling, filtering, and other cleansing processes.

Soil.—The geological strata under the soil exercise a considerable influence on the life of plants and animals. These strata frequently determine the composition of the waters which are drunk and used. They vary in chemical composition and physical properties, and have varying relations to heat and moisture. Some soils absorb heat, and keep up the temperature of a district. This is the case more or less with sandy, gravelly soils. Such soils do not retain moisture; and as moisture is necessary to animal and vegetable growth and decomposition, they are more free from malarious and continued fevers, and neuralgiæ, than other soils.

A clay soil retains moisture, and is always damp. On this account it encourages animal and vegetable growth and decomposition. It is drained with difficulty, and is rendered colder by the amount of moisture it contains. Mists

and fogs are more likely to occur on moist clay soils than on dry gravelly ones.

Limestone and sandstone soils heat or cool very rapidly. At the same time, they do not allow water to pass off very rapidly; and by retaining animal and vegetable matter, they are liable to generate poisonous miasmata during the heat of summer.

Chalk, like gravel, allows the free percolation of water, and does not rapidly absorb heat. It absorbs moisture, and the atmosphere is dry over it. Next to a gravelly soil, a chalk soil may be regarded as most healthy. There are many combinations of soil which need to be looked to in providing for the sanitary welfare of those who live upon them.

(B.) *Internal Agents.*

Another set of agencies are those which act more directly on the functions of the body, and which may be generally included under the heads of food, clothing, exercise, and mental and moral culture.

Food.—The human body, like other organisms, is composed of material elements. These are about eighteen in number. Four of these—carbon, hydrogen, nitrogen, and oxygen—are called *organic* elements, on account of their universal presence in living organized bodies. Two—sulphur and phosphorus—are very generally present, and are called *pseudorganic* elements. The rest are inorganic elements, and consist of the non-metallic elements, chlorine, iodine, and silicon; and the metals, potassium, calcium, sodium, magnesium, iron, and three or four others occasionally present.

These elements exist in compounds which form the tissues of the body. They are generally introduced into the body in the form in which they are found there. These compounds are found in the mineral, vegetable, and animal world; and when consumed by the animal, are called food. Food subserves two principal purposes in the system of animals: 1. It builds up the fabric of the body; 2. It maintains its special animal heat.

For the performance of these two great functions, special compounds are adapted. Thus, water, the compounds of the inorganic elements, and the nitrogenous compounds of plants, are employed for the performance of the first function; and starch, oils, and sugar for the second. There are, however, certain compounds consumed especially by man which act more particularly on the nervous system, as tea, coffee, alcohol, and tobacco, which may be called medicinal or auxiliary food. The food of man, with the exception of water and salt, is mostly derived from the vegetable kingdom. It is the plant which acts upon the organic elements in such a manner as to form fit compounds for the tissues of animals. The following outline of the food of man will afford an idea of its nature and relations to his life:—

I. *Alimentary or necessary*, which may be divided into three principal groups.

1. *Mineral.*

a. *Water.* Taken pure and in various beverages, and also contained largely in solid food.

b. *Salts.* Found largely in the ashes of all vegetable and animal food, and includes also common salt.

2. *Nitrogenous: nutritious or flesh-forming food.*

a. *Albumen.* Found in eggs, blood, and nervous tissue of animals, and in the juices of many plants.

b. *Fibrine*, also known as *gluten*. Found in the muscles of animals, and in the grains of the various cereal plants, as wheat, barley, maize, rice, &c.

c. *Caseine or legumine.* Found in the milk of the Mammalia, and separated as cheese, and also in the seeds of leguminous plants.

3. *Carbonaceous: respiratory or combustible foods.*

a. *Starch.* Found in almost all vegetable foods; and is pure in sago, tapioca, and arrow-root.

General
Hygiene.

General
Hygiene.

- b. Sugar.* Found in the milk and liver of animals, and in the juices and fruits of plants.
- c. Oil.* Found in the milk and fat of all animals, and in the seeds of many plants.
- II. *Medicinal and Auxiliary Foods.*
4. *Accessory Foods.* These, though constantly taken, are not digested, or appropriated, as,—
- a. Gum.* Found extensively in vegetable food.
- b. Cellulose.* The substance from which the walls of vegetable cells are formed.
- c. Gelatine.* The substance from which animal cells are formed, and constituting the basis of all animal soups and jellies.
5. *Alteratives.* To this group are assigned—
- a. Acids,* as vinegar, citric, malic, tartaric, and oxalic acids.
- b. Alkaloids.* The active principles of tea, coffee, and chocolate.
6. *Stimulants.* These act on the nervous system.
- a. Alcohol.* The active agent in beers, wines, and spirits.
- b. Volatile oils.* These give flavour to condiments and spices, as mustard, horse-radish, pepper, nutmegs, cinnamon, cloves, &c.
7. *Narcotics.* To this category is referred tobacco, opium, Indian hemp, and other narcotics indulged in by man.

The influence of food on health is most important. Man, left to himself, instinctively discovers what and how much he ought to take. But he is constantly placed in circumstances in which one group of these foods is abundant, and another is deficient. He is also, especially in childhood, dependent on others; and it is only by a knowledge of the requirements of the system that disease and death can be prevented. Food requires to be adapted to age, to seasons, to employment, to habits and conditions of the system.

The child, the youth, the adult, and the aged, all demand modifications of the diet. In hot countries and hot seasons, the heat-giving food, in proportion to the nutritious, requires to be diminished; whilst in cold climates and seasons, it needs to be increased. The hard-working man requires more nutrition than the man whose pursuits are sedentary. Some foods are particularly adapted to states of the system; thus oils and fats are beneficial in those conditions where there is a tendency to wasting from an undue absorption of fatty matter, or an insufficient supply of it. Water in large quantities frequently acts as a depurant, and its beneficial effects in certain states of the system have led to the folly of administering it in large quantities in all cases of disease.

The saline matters of the food may be deficient in the blood, and can be supplied by the administration of fresh vegetables, as seen in the case of scurvy. The alkaloids of tea and coffee act manifestly as retarders of the wasting processes of the body. Alcohol, in all its forms, produces most pernicious effects upon the body when taken in excess,—in fact, is the greatest dietetical curse of man; but in small quantities it excites the languid heart to action, and suspends those changes which might go on to the destruction of life and health.

Closely connected with the subject of food is that of cookery. Not only should food be of a proper kind, and given in due quantities, but it should be cooked in such a way as to insure its digestion and its ultimate action on the system. How little this is attended to, the least inquiry will make manifest. Those who professionally prepare or vend food know little of its properties and qualities; and the wealthy only secure a due supply of sustenance by an expenditure which is in the highest degree wasteful to themselves and injurious to the community in which they live. Our army, navy, schools, workhouses, prisons, and hospitals are supplied with food on no principle whatever; and disease and death are frequently the result.

The question of the relative digestibility of food, the action of the bile and the pancreatic fluid, the secretion from the mucous membranes of the intestines, and the evacuation of the undigested mass after the chyle is absorbed,—all demand study, in order to secure the sanitary action of food.

General
Hygiene.

Another important practical question in relation to public health is the adulteration and sale of impure food. This question has recently received the attention of the legislature, and more stringent measures are likely to be taken for the suppression of these practices. That the adulteration of food is carried to an injurious extent has been sufficiently proved; whilst through ignorance persons frequently sell food in a state likely to produce disease.

Clothing.—In a civilized state, man clothes himself, and by this means saves a large amount of wear and tear in the system. In cold and temperate climates, exposure naked to cold would destroy a vast amount of young life at once, and lead to the early destruction of mature life. At the same time, the surface of the body requires a certain amount of cooling in the hotter seasons of the year; so that the subject of clothing is one of considerable importance in a sanitary point of view.

Children are more influenced by cold than adults, and should be warmly clothed whenever the temperature is below 60° Fahrenheit. To a neglect of this rule may be traced the destruction of a large amount of infant life in this country. Neither the chest nor the legs of young children are sufficiently clothed in winter. Women also dress too lightly about the chest in the winter of these climates. Hence their liability to bronchitic attacks. In dressing, it should be remembered that all clothing made of animal substances is warmer than that made of vegetable fabrics. The head is naturally clothed, and needs perhaps less attention than it receives. If warm clothing is needed in cold climates and weather, it becomes oppressive in hot climates and weather. As the temperature rises above 65°, woollen clothing of all kinds may be exchanged for cotton and linen. The custom of clothing European troops in their woollen dresses, and hot and heavy head-dresses, in hot and tropical climates, is opposed to reason, and exceedingly destructive of health. The colour of clothes is also of importance. Economy dictates dark colours as showing the dirt less; but dark colours absorb heat in the summer when it is not wanted, and radiate heat in the winter when it needs to be husbanded. White and light-coloured clothing is that which is best adapted for clothing at all seasons and in all climates of the world.

Exercise.—The calling into play the action of the voluntary is called exercise. The contraction of the muscular tissue is attended with the destruction of a certain amount of the particles of which it is composed. This renders a restorative necessary, the blood is drawn upon for new matters, the capillary circulation is increased in the muscles moving, a corresponding increase of action takes place in the capillaries of the lungs, the inspiration becomes deeper and more frequent, the heart is stimulated to action, and the circulation of the blood is more rapid in every part of the body; the secreting surfaces are more active, the skin perspires, the exhalation of carbonic acid and moisture from the lungs is greater, and the whole system sustains an increase of activity. Of course such effects are more or less extensive according to the nature of the exercise. It may be of so violent a kind as to embarrass the heart and lungs, and where these organs are weak or damaged death may ensue. Health is, however, connected with a due exercise of all the muscles. In many trades, particular sets of muscles are called into action to the exclusion of others. The want of exercise in the latter may be productive of disease. The excessive exertion of the voluntary muscles in laborious occupations tends to waste the system and destroy life; whilst a life of freedom from muscular exertion permits the degradation of the tissues of the body, and an accumulation of fatty matter, which invites the attacks of disease or ends in sudden death.

To diminish the destruction of life by over-exertion, and to supply such exercises as will maintain health, are the

General Hygiene.

objects of the sanitarian. When the occupation does not involve a sufficient amount of exercise, the movements of the body involved in walking, running, jumping, riding, driving, rowing, swimming, fencing, declaiming, and reading aloud, may be recommended. A regular system of gymnastic exercises may be adopted with advantage in schools. For the sedentary classes of our artisans and commercial population public play-grounds are strongly to be recommended, in which games and exercises might be engaged in and adapted to the special wants of those using them.

Connected with exercise is the subject of *rest*. The voluntary muscular system, and the nervous system through which it acts, need rest. Continuous voluntary exertion exhausts more than the same amount of labour with rest. Periods of hard work and exercise should be intermitted with periods of cessation from exertion. This applies also to mental labour. Nature secures a certain amount of rest during meals; but the grand rest of the system is *sleep*. During the period of infantile and youthful excitability, sleep needs to be of longer duration than with the adult. For man in his vigour a certain amount of sleep is essential to his well-being. Thousands die for want of sleep, produced either by anxiety or a determination to shorten the hours of repose. As a rule, it may be said that the healthy hard-working man requires, in every twenty-four hours, *eight hours in bed*. Many can do with less, but none will ever repent securing this amount of rest. Some even require nine. Persons may go on for years despising this rule, but in the end the nervous system exacts from those who over-work it a fearful penalty.

Mental and Moral Culture.—The special functions of the brain and nervous system require attention from those who would preserve the health of the human body. What is true of any other general function is true here; a partial or excessive culture of the functions of the nervous system is likely to engender disease. Unless there is a harmonious development of the perceptive and reflective powers, and a proper development of the will, the human being is subject to the control of passions and feelings which lead to the most destructive effects upon the rest of the system. The neglect of the rules of sanitary science, seen in the destruction of thousands and tens of thousands of lives annually, points to the necessity of intellectual culture for the safety of the race; whilst the records of insanity and crime show how painfully society pays for the neglect of a proper culture of the moral and emotional nature of man.

3. SPECIAL MORBID AGENCIES.

The human body is liable to certain specific forms of disease, arising from the introduction into the blood from without of certain substances which act as poisons. As a rule, mineral substances, which are not naturally contained in the human body, act as poisons. These substances are often used for the purposes of suicide and murder. They are not, however, placed in the category of substances producing specific diseases. Such substances are produced either in the living tissues of plants and animals, or result from their decomposition. Such poisons may be divided into those generated in the bodies of living animals and plants, and those produced by vegetable and animal decomposition. Those generated in the living animal body may be divided into those produced in the human body, and those produced in the lower animals. Amongst the latter poisons may be enumerated those produced in the dog in hydrophobia, and in the horse in glanders.

Amongst the poisons generated in the human body may be mentioned those of syphilis, small-pox, scarlet fever, measles, diphtheria, typhus fever, typhoid fever, plague, whooping-cough, and cholera. In these instances the system

has the power of generating a poison which, when brought in contact with another human body, is capable of inducing in it the same form of disease as that in which itself was produced.

We may here pass over the consideration of poisons produced in living plants, as they are only accidentally or designedly introduced into the system.

Dead animal and vegetable matters are capable of entering into a state of decomposition, in which they may be taken into the body as food, or in which their particles may be diffused through the air, and thus introduced by the agency of the lungs into the blood. Such poisons, under the names of malaria and miasmata, are known to be capable of inducing disease in the human body.

All these poisons are more or less under the control of human agency. Where the poisons generated in the human body prevail, there strict quarantine, or measures for diluting the poison, do not fail to prevent the spread of disease. In the case of the putrid poisons, the removal of the cause, or the removal of persons from their influence, is known to avert disease.

In considering the action of these poisons, and the best means of rendering them inert, three things should be borne in mind: 1. The body attacked, or likely to be attacked; 2. The medium through which the poison is transmitted; 3. The poison itself.

With regard to the human being, it should always be recollected, with regard to all these poisons, that some persons are highly susceptible of their action, or predisposed to receive them, whilst others present none of this susceptibility or predisposition. A person vaccinated, or who has had the small-pox, will not contract small-pox on exposure to the contagion. It is no proof of the non-contagiousness of a disease that all persons exposed to its action do not acquire the disease. The subject of the causes that render some persons liable to take certain diseases, and others not, is worthy all attention, as tending to throw light on the spread and propagation of contagious diseases. Some of the diseases referred to are only propagated by contact with the diseased body, as syphilis and hydrophobia; but the majority of them are propagated by the poisonous matters passing through the atmosphere. This is a point of great practical importance. Still and moist states of the atmosphere are those which most favour the passage of poisonous gases. Currents of air will, however, convey the poison to a distance. The more concentrated the poison is in the atmosphere, the more likely it is to communicate disease. Infection may be avoided by the current being carried away from an exposed body; and the poison may be so diluted as not to produce an impression on even a predisposed body.

The nature of the poison differs. In some instances it is so intense that a small quantity will reproduce the disease in a predisposed body, whilst in others free exposure is required. As instances of intense poison, those of scarlet fever and small-pox may be given; whilst the poison of cholera and typhoid fever are of a much less intense kind.

Poisons seem to differ at different times and seasons. They are much more vigorous at the breaking out of an epidemic than at its close. They sometimes are so feeble that individual cases occur, and no spread of the disease results; at other times it would appear that diseases become epidemic from assuming a poisonous activity that ordinarily do not present this phenomenon. Thus, under some circumstances erysipelas and dysentery become highly contagious, whilst in their ordinary forms they exhibit no tendency to spread. It would even appear that diseased germs are susceptible of transformation; that at one period they shall produce one form of disease, and at another time another. These points are most important to bear in mind in dealing

General Hygiene.

Special Hygiene. with the outbreak of various forms of contagious and epidemic diseases.

PART II.—SPECIAL OR PARTICULAR HYGIENE.

It is not enough to inquire into the general laws of vitality, or to ascertain what are the necessary conditions of health and comfort, but an application of this knowledge must be made to the various sanitary wants of a community, and to the hygienic demands of industry. This is the aim of practical and especial hygiene. It has for its objects a minute acquaintance with the habits and occupations of the people, a particular knowledge of all the circumstances affecting the health of a community, and the application of rules and remedies to the many unwholesome influences that spring out of a social existence. It takes cognisance of the geographical situation of towns, the arrangement of streets, the construction of houses, the cleansing of the public way, the supply of pure water, the burial of the dead, and the removal of all corrupting refuse. It also concerns itself with the adulterations of food, the unwholesome influences of trade, and the injuries to which labour is exposed. All these, therefore, will form the subjects of consideration.

CHAP. I.—THE SITUATION AND CONSTRUCTION OF HOUSES.

Although these are matters of great importance, in a sanitary point of view, yet they receive but little attention from builders and architects; in fact, the condition of our towns, and the way in which cities are enlarged and remodelled, show that hardly a thought is bestowed on the advantages of situation, or on the general arrangement of streets; and in respect of the houses themselves, they are characterised by a showy exterior rather than by any design for internal comfort. In most cases the rooms are low and badly constructed for warmth and ventilation; the walls are composed of materials that offer but slight resistance to damp and cold; the windows are small, and so badly situated as to give no facilities for the admission of light and air; the passages are dark and narrow; and the whole fabric is cheerless and uncomfortable. Besides which, the houses are crowded together, and tower up to an unnecessary height. They thus darken the narrow and crooked thoroughfares; and are arranged without regard to the direction of the light or the course of the wind: in fact, it would almost seem as if every effort had been made to bar out the wholesome influences of nature. All this tells upon the vigour of the population; for it not only shortens life and engenders diseases of a low type, but it also saps the strength of the community, and more than decimates the infant population.

Again, it too often happens that the poor are lodged in the dilapidated houses of the rich, where it is impossible to secure for them the appliances which are necessary for health and comfort. A large share of the immorality and disease of our large cities is due to this, and to the indiscriminate association of the sexes which such a condition of things is sure to encourage.

It is not possible, however, to discuss in this place the several details of such an inquiry; and therefore we must be content with an exposition of the general principles of the subject. That which should be aimed at in the construction of our dwellings is—

1. The selection of a locality which is not in itself unwholesome, as from the proximity of marshy ground or stagnant water. It should not be so elevated as to be exposed to undue cold, nor so low as to be deprived of the salutary influences of a dry and bracing atmosphere.

2. The ground should be firm, dry, and porous; and it should permit of easy and natural drainage. A damp clay

soil is especially objectionable, and so also is a wet and peaty humus; for both of them provoke diseases of a malarious type.

3. The aspect of the building should allow a free access of air and light; and the principal windows should be so placed as to receive the direct rays of the sun, and to transmit a current of air that may sweep through the house when it is needed.

4. The walls should be constructed of materials that do not retain damp or organic impurity.

5. The houses should stand apart whenever it is possible. And

6. The streets should be arranged so as to receive the sun's light, and be open to a free current of air.

CHAP. II.—ON THE WARMING OF BUILDINGS, &c.

Warming of Buildings.—As the ventilation of buildings will be found treated in another place in this work (see VENTILATION), nothing requires to be said of it here. This chapter shall therefore be devoted to the warming of buildings, &c. The circumstances which render this necessary are the entrance of cold air by the doors and windows, the conducting power of the walls, and the radiation of heat from the glass of the windows. The walls are generally from two to four degrees below the mean temperature of the room, and they absorb and conduct a large amount of heat. The cooling effect of glass is also very great; for a square foot of glass will generally cool about 1·3 cubic feet of air per minute from the mean temperature of the room to that of the external air, and the cooling effect of metal or corrugated iron is nearly the same. Taking these facts into consideration, the rule which is generally adopted for maintaining the warmth of a room or public building at a genial temperature of from 60° to 65° is, that the supply in cubic feet of warm air at this temperature should be equal to four times the number of people the room is intended to contain, added to eleven times the number of external doors and windows, added to 1·3 times the area of the exposed glass. If the windows are double, the radiations may be neglected; and if they are tight, there is no necessity to multiply them by eleven; for in these cases the provision or supply is simply for ventilation.

The means which have been adopted for effecting this are the open fire, the close stove, the system of flues for hot air, and the closed pipes for a current of steam or hot water.

Although the *open fire* is not an economical way of warming a room, yet it is generally adopted in this country because of its cheerful appearance and because of the abundance of fuel. In early times the fire was placed in the centre of the room, and there was a hole in the roof above to let out the smoke. Then came the first improvement of setting the fire against the wall, and of ornamenting the outlet with a turret and with louvre openings. After a time there was a further improvement of stone-screens over the fire to shut out the smoke; and in the fourteenth century the channel for the smoke was entirely enclosed; and thus were chimneys first designed. But for more than 200 years they were not generally used except in the houses of the wealthy; and even there the large fireplace, with its cramped seats within the chimney breast, and the high-back settle which acted as a screen to keep off the wind, were but imperfect methods of warming. As soon, however, as coal began to be used as the common fuel, attention was directed to the discharge of the offensive smoke from it, and the best means of economizing the heat. Then it was that the great improvements began to be effected in the construction of fire-places. The earliest of these were by Keslar of Frankfort (1614), Savot (1625), Glauber (1669), Delesme (1686), and the Cardinal de Polignac (1715). The last-named writer, under

Special Hygiene.

Special
Hygiene.

the name of M. Gauger, published the first philosophical treatise on the subject, and it contains the germs of almost every modern improvement. He showed the advantage of having the sides and back of the stove placed at such an angle as to reflect the radiant heat into the room; and he also recommended that the chimney should be contracted immediately over the fire, so as to prevent the too rapid ascent of the heated air. These suggestions were still further improved by Franklin (1774), and by Count Rumford (1796); and since then the chief improvements have been in the methods of supplying the fuel, as from below or at the sides of the fire, and in directing the current of air upon it or through it. These improvements are countless, but the rules to be deduced from them are,—

1. That the fire-place should be in the situation which commands all parts of the room, and is as nearly as possible at equal distances from the confines of it; so that the radiant heat may be equally diffused.
2. It should be raised to about 10 inches from the floor, so that the feet may be warmed and the face not scorched.
3. The grate should have a large frontage, of a semicircular form.
4. The back and sides should be composed of bad conductors (as of fire-brick), so that the heat may be stored as well as steadily radiated.
5. The bars should be as small as possible, in order that the fire may burn clear, and the heat be freely radiated.
6. The aperture for carrying off the smoke should be narrowed to the minimum size, in order that the heat may be retained, and the fire made to burn steadily.
7. The chimney should be as perpendicular as possible beyond the gathering.
8. The coverings or sides of the grate should be placed obliquely at an angle of 45° to the front, and they should be well polished.
9. The distribution of warm air into the apartment should be promoted by air chambers around the grate and flues, and the supply of air to the grate should be under the floor, as in the contrivances of Mr Boyd.

With all these arrangements, however, there is a great loss of heat, and there are many strong objections to the open fire-place. Thus:—

The waste of fuel and of heat is enormous, for at least seven-eighths of the heat of the fire passes up the chimney, and is lost (Dr Arnott). Count Rumford estimated it at fourteen-fifteenths. Then, again, there is a very unequal effect in the distribution of the heat. Those who are near to the fire are too warm, and those who are away from it are not warmed at all; the law of radiation being, that the effects are inversely as the squares of the distances.

Another objection is, that the fire causes an uncomfortable draught along the floor of the room, and does not ventilate those parts which are above the level of the chimney breast.

And, lastly, there is a great deal of dirt and smoke, and there is danger of fire.

With all these disadvantages, however, our national habits have confirmed us in the choice of an open fire.

The close stove is used where fuel is scarce, or where the open fire is not admissible. It is a very ancient mode of warming, and is still commonly practised on the Continent.

The several varieties of stoves are,—Those which warm the air of the room by simple contact with the heated surface of the stove; those which supply a continuous current of hot air into the room; and those which deliver the warm products of combustion into the apartment. Of all these, the two former alone deserve consideration; for the latter are dangerous and unwholesome. Of the first, the simplest is the Dutch stove, which consists of an iron

chamber in which the fuel is burnt. The stove is raised a little above the floor, and the products of combustion are carried off by a flue. In France, Germany, Sweden, and Russia, the stove is made of brick-tiles or porcelain. The fire-place is small, but there is a circuitous disposition of the flue, and this makes the stove a large and inelegant structure. The materials, however, retain the heat for a long time, and therefore the stove requires but little attention, and is very economical.

When the warm products of combustion are conveyed into the room, as is the case with the common brazier, with Harper and Joyce's stoves, and with the various gas furnaces which have lately been contrived, there is great danger to health; for not only is the atmosphere made dry and hot, but it contains the poisonous products of combustion, which have on several occasions been fatal: in fact, the objections to most of the close stoves, whether they throw the products into the room or not, are, that they burn or overheat the atmosphere, and make it dry and uncomfortable. Besides which, they do not generally permit of a very complete renovation of the air, but merely cause a continual circulation of it within the room. To guard against these objections, the stove should be constructed so as to deliver the products of combustion entirely out of the room, and it should not be composed of materials that will soon become hot. The fire should never be so intense as to scorch the air, for that will produce a sensation of dryness and oppression. The supply of fresh air should be continuous, and the vitiated atmosphere should be removed by special contrivances at a higher level. A proper degree of humidity should be given to the air by means of evaporating vessels or wet surfaces, and there should be perfect and easy control over all the arrangements. When this is the case, the close stove has advantages over the open fire, in the circumstance of its being more economical and more uniform in its action.

A system of flues for hot air has been a common mode of warming among the wealthy from very early times. The Roman *hypocaustum* was but a set of flues running beneath the flooring, and conveying the smoke and hot air from a furnace outside the room. Exactly the same kind of arrangement is the ancient *hang* of the Chinese; and the modern invention of Mr Beaumont is also an example of it. Judging from the effects of these stoves, and the economy with which they may be maintained, they appear to have many advantages; but they require especial attention, and are not always under control; besides which, there is danger of the soot firing in the flues, and so becoming unmanageable; and, above all, they cannot be made the means of constant ventilation.

A closed pipe conveying steam or hot water is a modern invention. The effects are much more genial than those produced by a higher temperature, but the apparatus is expensive, and in the case of steam it requires constant attention; nevertheless, it is used with advantage in large public buildings, as in hospitals, prisons, barracks, &c.

The hot-water apparatus, in its simplest form (Kewley's), is on the principle of a syphon. It consists of a long pipe coiled about in the rooms to be heated, and having two legs of unequal length passing down into an open kitchen boiler; the short leg dips just under the surface of the water, and the long leg passes to the bottom of the boiler. As the water becomes hot, it rises in the short leg and circulates to the coils in the upper level, where it parts with its heat, and then descends in the long leg to the boiler. The apparatus is not adapted for any great height (not above 14 feet), and the water cannot be heated above 180° because of the tendency to a vacuum.

The second form of the apparatus is that contrived by the Marquis de Chabannes. It consists of a closed boiler, with the two legs of the syphon communica-

Special
Hygiene.

Special
Hygiene.

ting with a cistern at a high level. These are filled with water, and when the fire heats the contents of the boiler, the hot water rises at once to the cistern, whence it is distributed by coils to the rooms to be heated, and then it descends to the boiler. By this arrangement the temperature may be raised to 212°, and the water conveyed to any distance.

The third and only other form of the apparatus is the invention of Mr Perkins. It is a closed circuit of comparatively small pipes filled with water. About one-eleventh part of the whole tube is coiled in a suitable manner, and placed in a furnace at the lowest level. From this a straight tube passes to the top of the building, and thence the pipe descends to the several rooms to be warmed, where it is coiled so as to expose a large radiating surface; from these it returns to the coil in the furnace. An expansion or safety tube is placed at the uppermost part of the apparatus, to guard against danger from the too great expansion of the heated water. The temperature of the water in the furnace coil may be raised to 400°, but the circulation and cooling in the return coils is so great that the water soon falls to 200°; in fact, when the return coils have a radiating surface about ten times as great as that of the furnace coil, it is hardly possible to maintain a temperature above 200°.

The quantity of heat given out by these contrivances is somewhat variable; but a cubic foot of steam at 212°

ought to give out enough heat to raise 180 cubic feet of air 10°, and a cubic foot of water will raise the temperature of about 3000 cubic feet of air one degree for every degree of heat it loses. Tredgold, Hood, and others, have given the rules for ascertaining the length and surface-measurement of pipe which is necessary for heating given quantities of air, and have also determined the amounts of the different kinds of fuel which are required for the purpose; but this is not the place for the consideration of such facts.

Artificial Illumination.—In a sanitary point of view, this is a subject of great importance, for all the combustible bodies employed for the production of artificial light appropriate the oxygen of the air and form carbonic acid. They therefore vitiate the atmosphere to a large extent, and some of them also produce sulphurous acid, which by subsequent oxidation becomes sulphuric acid, and this exerts a corrosive action on metals and textile fabrics.

The principal illuminating agents are oil, tallow, stearic acid, spermaceti, wax, camphine, benzole, and coal-gas. The extent to which these several agents appropriate the atmospheric oxygen, evolve heat, and vitiate the air for the same amount of light, may be seen in the following table. The light evolved in each case is that of 26 sperm candles, each burning at the rate of 120 grains per hour; and the vitiating effect is calculated at the rate of 3 parts of carbonic acid in 1000 of air.

Special
Hygiene.

Illuminating Agent.	Consumption of each Burner or Candle per hour.	Number of Burners or Candles required.	Heating Power in Cubic Feet of Air raised 10 Degrees.	Quantity of Oxygen consumed in cubic feet.	Quantity of Carbonic Acid produced in cubic feet.	Quantity of Air vitiated and consumed per hour in cubic feet.
Cannel gas	3.5 cub. ft.	2	22,500	7.92	3.91	1307
Benzole	285 grs.	5	19,340	7.35	5.89	1970
Camphine	376 „	4	20,530	8.37	6.02	2016
Common coal-gas	5 cub. ft.	2	32,400	12.87	6.40	2146
Sperm-oil in Argand	686 grs.	3	31,200	10.10	7.10	2371
Colza-oil in Do.	756 „	3	27,150	11.08	7.80	2608
Sperm-candles, 6 to the lb.	136 „	23	37,800	16.29	11.40	3811
Oil in a common lamp	133 „	27	43,600	17.62	12.39	4142
Wax candles, 6 to the lb.	168 „	21	40,800	17.91	12.60	4212
Stearic acid, do.	140 „	26	44,100	18.00	12.92	4318
Yellow moulds, do.	143 „	30	44,200	21.05	15.27	5108

From this it will be seen that, for the same amount of light obtained, the heating and vitiating effects of tallow candles are nearly four times as great as those of cannel gas; but then gas is not consumed economically; for the light is placed at a great altitude, and more gas is therefore burnt than is necessary to produce the required amount of illumination. This it is which has created so great a prejudice against gas, and which has caused it to be consumed in a wasteful manner, so as to heat and vitiate the atmosphere to a serious extent. In every case, however, it is manifest that the products of combustion should be discharged from the room, and that there should be a large supply of atmospheric air to provide for the heating effects of the illuminating agent.

The difference in the illuminating power and the vitiating effects of the same body (sperm-oil for example) is dependent on the way in which it is burnt, and it shows how necessary it is that combustion should always be maintained at the fullest point; indeed, the differences in the vitiating effects of the several fatty bodies are caused, not so much by differences of chemical composition, as by the vigour with which the combustion is maintained. It is therefore advisable that the supply of air to the combustible should be such as to maintain it in the most active state of combustion. This is the object of glass chimneys, of the various contrivances named oxydaters, of the thin and plaited wicks of candles, and of the expanded or sheet-like flames of gas. When the combustion is very feeble,

a number of acid compounds are produced which are very offensive. The fatty bodies, for example, when burnt with a smouldering wick, or a large snuff, produce acrolein, empyreumatic vapour, and irritating fatty acids; coal-gas, when slowly burning, produces aldehyde, formic acid, &c.; and the half-burnt vapours of turpentine and benzole are equally offensive.

Coal-gas is a very complex mixture; it consists of about 40 per cent. of hydrogen, nearly the same quantity of light carbonated hydrogen, from 5 to 10 per cent. of condensable hydro-carbons, with variable proportions of carbonic oxide, carbonic acid, bisulphuret of carbon, nitrogen, ammonia, and sometimes traces of sulphuretted hydrogen. Many of these gases are poisonous; and therefore it is that coal-gas exerts an injurious action on the animal economy. If it is inhaled in a concentrated state, it quickly produces insensibility, which is followed by coma and death. An atmosphere containing from 7 to 12 per cent. of coal-gas will kill small animals in a very short time; and this proportion acting on man, causes headache and nausea, with great depression of the vital powers.

A mixture of gas and atmospheric air is explosive; and it would seem from experiment that the greatest danger is when there is 1 part of common gas to from 6 to 7 of air, or 1 part of cannel gas to about 10 of air. The force of the explosion under these circumstances is equal to that of about 30 atmospheres. These circumstances call for especial care in the use of gas, and in many continental cities there are

Special
Hygiene.

authorized rules for the management of it. In Hamburg, for example, the gas-fitters are obliged to perform their work in an appointed manner. They must use tubes of wrought iron, or of brass, or copper; and in cases where these are not easily adapted, tubes of drawn tin must be employed. The joining must be made in a durable and solid way, either by means of sockets ground in and cemented with iron cement, or by screwing up, or by soldering. Any other kind of connection is forbidden. The tubes must be placed in localities where they are accessible, so that in case of leakage the mischief may be easily repaired. The cock must be constructed so as to make only a fourth part of a turn, and they must be fixed so as not to be removable from the tubes. All the pipes of one inch or more in diameter must be provided with stop-cocks, so as to shut off the gas in case of fire; and no one is permitted to use or alter the fittings without having them tested by means of a pressure of 1 inch of mercury or 14 inches of water. All the gas-fitters are sworn to adhere to these instructions; and in case of any damage from negligence, compensation can be claimed from the gas-fitter in a civil court of justice.

The sulphur which is contained in coal-gas is objectionable, because of its forming sulphurous acid, which soon absorbs oxygen from the air, and becomes sulphuric acid. This exerts a corrosive action on all kinds of textile fabrics, and has caused much mischief in libraries and warehouses; in fact, the amount of sulphur in 100 cubic feet of coal-gas is sufficient to produce from 30 to 50 grains of sulphuric acid. It is proper, therefore, to guard against the destructive effects of this acid by burning the gas in a closed chamber, so that the products of combustion may be carried entirely away; and there are many contrivances for accomplishing this.

A dangerous compound, called water-gas, has on several occasions been proposed for illuminating purposes. It consists of hydrogen, carbonic oxide, and carbonic acid, in various proportions; and to give it an illuminating power, it is naphthalized with benzole, or the volatile hydro-carbons of coal-tar. The gas is obtained by passing steam over ignited carbon, and the carbonic oxide which is so produced is a deadly poison; so much so, that the governments of France and Germany have interdicted its use.

There are two illuminating agents—namely, the oxy-hydrogen, or Drummond light, and the electric light—which do not vitiate the atmosphere; but they are so costly, and are so difficult to manage, that they are not used for domestic purposes.

Water Supply.—An abundant supply of wholesome water is one of the first essentials of health and comfort.

Pure water cannot be obtained from natural sources; even that which distils from the earth, and falls as rain or snow, is charged with volatile matters which are often highly offensive; and the water which flows from the soil contains saline impurities which have been derived from the strata through which it has percolated. These are the earthy carbonates of lime and magnesia, the chlorides of the alkalis, the earthy and alkaline sulphates, with silica, alumina, organic matter, and frequently the nitrates of potash, soda, and lime. The proportions of these constituents vary with the nature of the soil through which the water has filtered; for example, the amount of carbonate of lime and magnesia may range from less than a grain per gallon to more than 20 grains, the former being the proportion in the water from the shallow sands of the tertiary strata, and the latter in the water from the chalk formation. So also with respect to sulphate of lime: in most of the streams of England, and in the water-bearing strata, the proportion does not exceed 5 grains per gallon; but in the hard selenitic waters of the London clay the proportion is from 20 to 30 grains. The existence of nitrates in water

is generally a sign of putrid contamination. All the shallow wells of our large towns and cities are charged to a considerable extent with this salt, the acid of which is produced by the oxidation of organic matters which have drained from the sewers, and cesspools, and graveyards, and from the soakage of surface filth. While the soil is capable of producing this salutary kind of oxidation, the danger is kept in abeyance; but no one can say when this power may cease or be overtaxed, and then the danger is imminent. Water which has flowed from well-manured land is charged in the same way with alkaline nitrates; and that which has drained from a soil covered with peat, or has stood upon decaying vegetable matter, as the water of ponds and marshes, is commonly impregnated with organic compounds to a serious extent. As a rule, it is found that the water from the surface of the soil is not wholesome unless it has been collected in a sandy district which is not in cultivation. Those from the upper sands of the tertiary strata are generally excessively hard, from the presence of sulphate of lime. Those from the lowermost sands of that strata, as the deep well waters of London, are free from this impurity, and are frequently alkaline, from the presence of carbonate of soda. The water from the upper and middle layers of chalk is characterised by the existence of much carbonate of lime; and that from the upper greensands which lie upon the gault is not much charged with calcareous salts, but contains a rather large proportion of alkaline nitrates, with traces of phosphates. In the summer-time such water is soon covered with *Conferva* and *Diatomacææ*, which feed upon the nitro-phosphates, and form a thick scum upon its surface. The water from the sands below the gault is commonly the purest of all; but even this is occasionally impregnated with sulphate of iron that has been produced by the oxidation of non pyrites. River waters have generally lost a great portion of their calcareous matter, from the escape of carbonic acid. A water which contains about 20 grains of saline matter in the gallon, of which about 12 or 13 are carbonate of lime, from 2 to 3 sulphate of lime, from 2 to 3 common salt, and with not more than 2 grains of organic matter, is generally well suited for domestic purposes. If it contain a larger proportion of carbonate of lime, it is unpleasantly hard, and causes a waste of soap, besides depositing a crust upon the interior of the vessels in which it is boiled. Every grain of carbonate of lime that remains in solution in the water destroys about 10 grains of soap; and therefore a calcareous water is wasteful for domestic purposes. When the calcareous salt is in the form of sulphate of lime, it is still more objectionable, because this salt is not precipitated from the water by boiling or by the addition of an alkali. The hardness is therefore said to be permanent, in contradistinction of the fugitive hardness of a carbonated salt. Such water not only destroys soap to the extent of about $7\frac{1}{2}$ times the weight of the sulphate contained in it, but it is unfit for vegetable infusions, and for extracting albuminous matters. There are occasions, however, when this is desirable, as in the brewing of pale ales, when the object is to extract the saccharine matter of the malt, without much of the colour or the albumen. The water of Burton-upon-Trent, for example, which is so celebrated for the production of pale ale, contains about 28 grains of sulphate of lime in the gallon.

In consequence of the objections which have been raised to the hardness of calcareous waters, several processes have been suggested for the purpose of softening them. None of these processes, however, are applicable to the selenitic waters, which derive their hardness from sulphate of lime. In other cases they owe their action to the removal of the carbonic acid which holds the carbonate of lime in solution. Exposure to the air in a running stream, or boiling the water for a few minutes, or the addition of caustic lime,

Special
Hygiene.

Special
Hygiene.

which is Dr Clark's process, will have this effect, and then the carbonate of lime is thrown down as a white insoluble powder. The latter process, which was suggested by Dr Clark in 1841, is generally thought to be the most effectual, but it has not yet been practised with success; for there is much difficulty in removing the precipitate from the water, and the suspended lime is apt to form concretions in the service-pipes. The quantity of lime which is necessary for the purpose will depend upon the hardness of the water; but it rarely exceeds 10 grains per gallon, and with this proportion the hardness of a chalk water may be reduced from 19 or 20 degrees to 6 or 7.

A water which contains but little carbonate or sulphate of lime, although soft and agreeable for domestic purposes, is apt to be dangerous, from its action on the lead of the cisterns or service-pipes. Experiments have shown that pure distilled water rapidly corrodes lead, and so does rain and snow water, and the water which has fallen upon sandy districts, and has not received much mineral impregnation. The corrosion of the lead, which is due to the combined influence of water and atmospheric oxygen, leads to the formation of the white hydrated oxide of the metal; and this, by combining with carbonic acid, becomes a hydrated carbonate. Part of this is thrown down as a white precipitate; part of it is also suspended in the water, and gives it a milky appearance; and a still smaller part, amounting to about 7 grains in the gallon in the case of the hydrated oxide, and $1\frac{1}{2}$ grain in the gallon with the hydrated carbonate, are dissolved. These proportions of lead are quite sufficient to give to the water a poisonous action: indeed, as little as 1 grain of oxide of lead in 7 gallons of water has been known to act injuriously (Herepath); and 1 grain in the gallon has often produced lead-poisoning. The proportion which is thought to be harmless is 1 grain of lead in 20 gallons of water (Smith); and when it rises to about 1 grain in 10 gallons, it is approaching a dangerous quantity.

The facts which have been made out in respect of the action of water on lead are these:—That water which contains less than 2 grains of saline matter in the gallon cannot be safely stored in lead vessels or distributed through lead pipes. That a proportion of 6 grains of saline matter (chiefly carbonate and sulphate) may be distributed through lead pipes, but cannot be stored in lead vessels; and that when the proportion of sulphates and carbonates amounts to from 10 to 20 grains per gallon, the water is not affected by the lead to any appreciable extent. These facts show that there is danger in seeking for a too pure supply, or in softening the water to a very great extent.

Again, the presence of nitrates or chlorides, or an excess of carbonic acid, will also cause an injurious action on lead; and so will the falling in of leaves or dirt into a lead cistern, or the joining of iron pipes to the lead. The former in their decay produce a vegetable acid which dissolves the lead, and the latter sets up galvanic action, which corrodes it. Cases of lead-poisoning have occurred where lead pipes have been joined to iron ones; and it has sometimes happened, that although the water which flows through the pipe is wholesome, that which has stood in it for some hours is poisonous. This explains the fact, that in a large household the domestics who make their morning tea of the water which has stood in the pipes all night, will show symptoms of lead-poisoning, while the rest of the family are free from them.

In seeking for a supply of water, therefore, it is necessary to guard, on the one hand, against the existence of too large a quantity of saline matter, and on the other, to avoid that degree of softness or purity which will lead to an injurious action on the lead of the cistern or service-pipe. Water which contains nitrate or chloride in excess or solid vegetable matter, should always be rejected.

VOL. XIX.

Special
Hygiene.

The *mode of supply* is likewise a matter of importance. Whenever it is practicable, the water should be conveyed to the storing places in covered channels, so as to prevent as far as possible the contamination of the water with filth. The reservoirs should also be covered; and the water should remain in them a sufficient time to deposit the grosser impurities. It should then be filtered through sand-beds into the reservoirs from which it is supplied to the public. As to the question of an intermittent or constant supply, there are many arguments of great weight which bear upon both sides of it. The advantages of a constant supply are, that the necessity for large cisterns, and the consequent exposure of the water to fouling, is greatly diminished; the water comes to the house cool and well aerated; and it is always ready for use. The disadvantages are, that the necessity for cisterns cannot be entirely obviated; that there is a great waste of water in the continuous flow of it; that it is delivered at so slow a rate that there is a needless loss of time in collecting it; that it cannot be supplied at a high pressure; that the pipes are apt to freeze; that when repairs are going on there is a total shutting off of the supply; and that the continuous flow is never sufficient to clean the drains or to flush the sewers. Besides which, in almost every case where the constant supply has been generally used, there have been practical difficulties, chiefly on the score of excessive waste, which have interfered with its continual action. The truth is, that in the houses of the wealthy and the careful it is a matter of little or no importance whether the supply is constant or intermittent; for, with proper attention to the state of the cistern, the supply is always sufficient and unpolluted; but in the dwellings of the poor, where the receptacle for the water is generally an open butt, receiving all the chance filth which may drop into it, and becoming tainted with the disgusting exhalations from the neighbouring closet, to say nothing of the insufficient capacity of the receptacle, it is a matter of serious moment whether there cannot be a perpetual flow. At any rate, there is some better system required than that which prevails in all the crowded localities of our great cities, where it is hard for the poor to obtain even that modicum of water which is required for their physiological wants, and where it is vain to expect from them those habits of cleanliness which are necessary for health, and for their social advancement.

As to the *quantity* of supply, it is manifest that it should be sufficient not only for the domestic wants of a population, but also for the purposes of trade and luxury. In the city of London it amounts to nearly 25 gallons per head per day; and in the cities and towns of Glasgow, Aberdeen, Nottingham, Preston, Oldham, Liverpool, Paisley, and some other places which are regarded as models in this respect, the daily supply is from 15 to 20 gallons per head. Looking, therefore, at the requirements of a population, and at the practical facts which have been ascertained concerning them, it may be concluded that a supply of from 12 to 15 gallons per head is required for purely domestic purposes, and that an addition of from 5 to 8 gallons per head is required for the purposes of trade and general cleanliness. This makes a total daily supply of 20 gallons per head; and this may be regarded as sufficient for domestic wants, for public baths and wash-houses, for the flushing of sewers, for the cleansing and watering of streets, for the extinction of fires, and for the supply of trades and manufactures.

The chief conditions of a water supply are:—

That the water should be of such purity and quality as to be fit for domestic purposes, without, on the one hand, being wasteful on the score of hardness, and on the other dangerous from its softness.

That it should be conveyed from its source in covered channels.

Special
Hygiene.

That it should be stored in reservoirs that will permit of sedimentation, and be filtered through fine sand.

That the daily supply should be not less than 20 gallons per head of the population.

That it should be supplied at high pressure, so as to reach the uppermost storeys of the houses.

That the cisterns of every house should be constructed of harmless and durable materials; that they should be covered so as to exclude dirt and other impurities; and that they should have a capacity of at least 12 gallons per head, or 24 gallons per room.

That every closet should have a distinct supply, so as to guard against offensive impregnation.

That every court should have a separate stand-cock that may be used for flushing and cleansing.

That there should be a street supply sufficient for the accidents and emergencies of fire.

And lastly, that there should be a proper distribution for street fountains, for public urinals, and for the flushing and cleansing of sewers.

Cleansing, Draining, and Sewering.—In providing for the sanitary wants of a community, it is not sufficient merely to procure and distribute an adequate supply of good and wholesome water, but means must be taken for the removal of that water after it has become foul in the services of life and industry. Provision must also be made for the drainage of the soil, and for the quick disposal of all the refuse matters which are apt to accumulate in every large city. The cleansing of the streets, and the removal of common refuse, are usually provided for in every town and hamlet, and are generally enforced with the utmost care and regularity; but the drainage of the soil, and the disposal of sewage and liquid waste, have yet to be dealt with, so as to be inoffensive and technically useful. This is a problem which has hitherto baffled the science of the chemist and the skill of the engineer; and the experience of the past, as well as the lamentable errors of the present, have left it doubtful whether the old system of cesspools, with the appliances of modern science, would not have been preferable to the wasteful and dangerous methods of modern sewerage; for the fact is dawning upon us, that every river in the country is being fouled by the reckless discharge into it of matters which are due to the soil. Not that we can go back to the careless habits of our forefathers, when every house incorporated its own stink, and stood upon an oozing cesspool; but it is a question of serious importance, whether, if as much attention and engineering skill had been bestowed upon the improvement of that system, and the perfection of the cesspool arrangements, a more profitable result would not have been obtained than the present; for, however great may appear to be the improvement of the public health through the adoption of the modern system of sewerage, we must not forget that the experiment is only in the first stage of its development, and that we have yet to learn what will be the ultimate effect of the pollution of every watercourse in the kingdom.

Judging from the facts which are before us, it appears evident that the surface and subsoil drainage of every town and city should be altogether distinct from the sewers and cesspools, and that while the drainage may be safely discharged into the nearest stream, the sewage of the population must be dealt with in an independent manner. That which must be provided for is the collection and disposal of about 40 ounces of excrementitious matter daily for each member of the community. Of this from 2 to 2½ ounces are dry solid, and with the present arrangements it is mixed with from 20 to 25 gallons of water, and is thus rendered unfit for every useful purpose; in fact, the matters contained in the public sewers consist not only of the solid and liquid ejecta of the population, but also of the fluid refuse of

Special
Hygiene.

every branch of industry. They are composed of the filth of kitchens, laundries, and dye-houses; the drainage of stables, slaughter-houses, and the public markets; the various liquid impurities of trade and manufacture; the washings of streets and alleys; and the whole water supply of the district. Each of these constituents has an influence on the composition of the general mass of sewage, and on the putrefaction to which it is subject. Analysis shows that the sewage of large towns contains from 15 to 80 grains per gallon of suspended matter, and from 35 to 76 of dissolved. Of the former about 35 per cent. is organic, and of the latter about 28 per cent. The mineral constituents are chiefly carbonate of lime and common salt, with small proportions of alkaline sulphate and earthy phosphate, together with the insoluble debris of the roads and the detritus of wheels and horse-shoes. The organic matter consists of the remains of vegetable and animal fibre, with a soluble extractive in a high state of decomposition. None of these can be utilized; and the organic constituents give off such an abundance of foul gases that they are a constant source of annoyance. The gases consist of about 73 per cent. of light carburetted hydrogen, 16 per cent. of carbonic acid, 10 of nitrogen, and traces of sulphuretted hydrogen, ammonia, and a putrid organic vapour that is in the highest degree offensive. Every gallon of sewage will discharge from 1½ to 1½ cubic inch of the gas every hour, and the fermentation continues for weeks. The effect of this in the atmosphere of the sewer is extremely dangerous, for wheresoever it escapes, like the emanations from cesspools and privies, it causes disease; in fact, it lowers the vital powers, produces nausea or actual sickness, and at length sets up a putrid form of fever which is exceedingly fatal. To prevent the escape of these gases the openings from the drains and gullies are trapped, and every effort is made to prevent the diffusion of the foetid gases into the houses and public way. But still the sewers must be ventilated; and to accomplish this, openings are left in the middle of the streets, out of which the gases pass without hindrance. It has been tried to ventilate the sewers by means of the rain-water pipes, or by tubes to the tops of the houses; but the foul gases diffuse themselves into the upper windows, and are offensive. It has also been proposed that the sewers should be ventilated by the street lamps, or by the church towers; but the only practical means of disposing of the gases is by the aid of charcoal placed in the course of the outlet channels. The efforts made to destroy the gases by means of furnace fires placed in special ventilating shafts have not been successful, partly because of the difficulty of effecting any large amount of ventilation in this manner, and partly because of the enormous expense which it involves.

Attempts have been made to diminish these evils by the use of small drainage pipes, instead of the large brick sewers which are commonly employed. It has been thought that, with a good arrangement of such pipes, the sewage would be quickly discharged, and would not have time to undergo the decomposition to which it is subject in the larger channels; that foul gases would not therefore be evolved from it; and that it could be more easily utilized than the putrid liquid matters of the common sewers. But these expectations have not been realized. In the towns of Croydon, Rugby, Tottenham, Uxbridge, and elsewhere, the system has failed; and experience has shown that it is not only an expensive system, but it is also a dangerous one, because of the mischief occasioned by the escape of foul gases when by accident a stoppage occurs in any of the pipes; for as there are no special contrivances for the outlet of the gases, they are forced through the traps and openings into the houses, and are thus a cause of annoyance and disease. Experience has also shown that the solid excreta which is thus collected cannot be utilized

Special
Hygiene.

with profit, and that the liquid refuse is as offensive, and is as difficult to dispose of, as the worst kinds of ordinary sewage.

That much has yet to be accomplished in respect of this matter, there can be no doubt; and in the meantime the objects to be kept in view are,—

The construction of special drains for the discharge of the surface and subsoil drainage, and for disposal of the less offensive sullage from the domestic use of the water supply.

The formation of special drains and receptacles for the removal of the animal excreta.

The construction of the sewage-channels and the cess-pools of impervious materials.

The occlusion, by means of traps, &c., of the sewer-gases from the houses and public way; and the providing of distinct ventilating channels with deodorizing trays of powdered charcoal.

The existence of proper regulations for cleansing the public way, and for removing the house refuse.

And the adoption of some profitable and inoffensive means of utilizing the sewage and waste products.

Offensive or Injurious Trades.—All pursuits and occupations have their influence on the health of those who are engaged in them: even the luxurious habits of the wealthy affect the condition of the body, and mark the evils of a too artificial state of existence. But this is not the place to discuss the special effects or particular maladies of each occupation, but rather to lay down such general rules for the management of offensive trades as may be applicable to the purposes of hygiene. And, in the first place, there are certain manufacturing processes which ought not to be conducted within the confines of a city; for they are either dangerous on account of the poisonous matters they discharge into the air or soil, or they are insufferably offensive. To the first of these belong the trades and occupations that deal with corrupting organic matter, and which poison the atmosphere with the products of putrid decomposition: among these are slaughterers and knackers, bone-boilers and catgut-spinners, tanners, and the makers of artificial manure. Nearly akin to these are the different processes of manufacturing chemists, as the making of mineral acids, the assaying and dissolving of metals, the roasting and smelting of ores, the preparing of lead and arsenical pigments, the distilling of crude pyroligneous acid, and the treatment of the various products of gas-making, as coal-tar and ammoniacal liquor. To the second belong the trades of tallow-melting, soap-boiling, tripe-dressing, gas-making, varnish-making, bleaching, &c., &c; but in all cases, whether the offensive operations are conducted within the confines of a town or not, it is proper that every care should be taken to prevent the escape of offensive effluvia; and this is necessary, not merely because of the nuisance occasioned by it, but also because of the fact that every particle of matter escaping from the domain of art is a loss to the manufacturer. Every effort should therefore be made to collect the volatile and waste products, so that they may be hereafter utilized; and if it so happens that the volatile product is not of sufficient value to pay for the cost of its collection, it should be destroyed or rendered innocuous by some special contrivance, as by conveying it through a flue into the furnace fire. In this manner the disgusting fumes from melting tallow, from boiling bones, or tripe, or whalebone, and from the making of varnishes, manures, and other such like offensive operations, may be consumed and rendered harmless.

Again, when it is necessary to collect or store materials that are apt to undergo decomposition, they should be placed in air-tight receptacles and treated with disinfectants; and when the storage of such materials is large, the chamber containing them should be ventilated by a fanner, and the offensive effluvia conveyed into a furnace

Special
Hygiene.

fire. All liquid products of a volatile or noxious character should be transported in casks or close barges, and should be stored in air-tight tanks. Nor should there be a larger stock of such materials than is necessary for the immediate requirements of trade.

And lastly, in every establishment where liquid organic substances are likely to soak into the soil and be offensive, the pavement should be impervious, and it should be laid upon a proper incline, so that the waste liquors may run off and be collected in a covered tank, or discharged into a public sewer. All the sinks and gullies should be effectively trapped, and there should be an abundant supply of water to ensure the needful cleansing. In addition to which, the business of the factory should be under such regulations as will prevent unnecessary annoyance.

There are some trades which are so dangerous and unwholesome as to require particular care on the part of the operatives. This is so in the manufacture of lead and arsenical pigments, in the making of lucifer-matches, and in the dry grinding of steel, &c. All these demand especial precautions. The buildings should be well ventilated; the operations should be conducted in a cleanly manner; there should be no waste of the dangerous products; the working clothes should not be worn out of the factory, and they should be frequently cleansed. Those who work in lead should drink a lemonade acidulated with sulphuric acid, and the lucifer-makers should use an alkaline beverage. Under all circumstances, the action of the dangerous matter should be checked as much as possible by cleanliness, by proper prophylactics, and by effective ventilation.

The discharge of opaque smoke into the atmosphere is nearly always a wasteful nuisance; for the evidence of those who are best able to judge of the matter is to the effect that it may be easily prevented, and that it ought not to be allowed. The mischief of it is, that it obscures the atmosphere, interferes with domestic cleanliness, begrimes the architecture of a city, and causes the inhabitants to shut out the air which is necessary to ventilation. The remedy is a little attention to the manner of supplying the fuel to the fire, or the employment of one of the countless contrivances which have lately been invented for the consumption of smoke.

The Burial of the Dead.—This has been a subject of sanitary regulation from the earliest times. The ceremonies of the Jews and ancient Egyptians, the processes of embalming which were practised by the Egyptians and Peruvians, and the burning of the dead by the Greeks, the Romans, and the Ethiopians, were but the means of preventing danger from putrefaction. And even in later times, when the Romans practised interment in the soil, it was performed in an allotted space beyond the walls of the city. Gradually, however, the custom of burying the dead within cities, and even within the temples of religion, was adopted, and at last it was learned how dangerous the practice was. As far back as the sixth century the mischief of it was anticipated, and edict after edict was promulgated by the church against it, but with little or no effect until the legislative enactments of different countries put a final check upon it. In France, Germany, America, and, lastly, in the metropolis of this country, the practice of intramural interment has been prohibited, but not until it was shown that the emanations from the dead were a fruitful source of danger to the living. It is a serious matter, that close beneath the feet of those who attend the services of the church, and all around the sacred edifice, there are heaps of human remains undergoing putrefactive decay, and evolving foul gases which are known to be a cause of disease. Instances are not rare where these gases have suddenly gushed forth, and have killed with the energy of a thunder-stroke; and often have they spread a pestilence that has decimated the neighbouring population. All this, with

Special
Hygiene.

the knowledge that the gaseous emanations of animal corruption are among the most deadly poisons with which we are acquainted, has led to the condemnation of intramural interment.

The questions which present themselves in respect of this matter are,—the situation of the place where the dead should be buried; the character of the soil which is best suited for the promotion of animal decay; the space which should be allotted for each interment; and the time which should elapse before a grave is disturbed. Add to these the treatment of the body before it is interred, and the manner of dealing with the present churchyards and overcrowded vaults.

The situation of a public cemetery is not an unimportant question; for it involves considerations of economy, of convenience, of reverence for the dead, as well as care for the living. It should be accessible by easy carriage-roads; and better still if it can also be approached by a railway; for this secures economy in the transport of the coffin and mourners, and does away with that worst of all necessities, the conveyance of the dead in cabs and other public vehicles. If the site be upon the side of a hill,—a situation which is always in harmony with the feelings of the sorrowful, and encourages that reverence for the dead to which all consideration is due,—it should be carefully ascertained that the drainage of the soil is not downwards into localities where the water is used for domestic purposes. The proximity to a well-wooded district, and a situation which will permit of complete isolation from dwellings, are always to be preferred.

The character of the soil which experience has proved is best suited for animal decay is a light porous soil, which will permit of atmospheric diffusion. A stratum of wet clay is most objectionable, and a peaty soil will have the effect of preserving the body for an indefinite time.

The graves should never be so close as to prevent the free access of air through the porous soil to the body, and the earth should never be saturated with that unctuous corruption which is characteristic of the overcharged graveyards of the metropolis. It must not be forgotten that the object of interment is to effect the complete decay of the body; and every facility should be offered for this purpose. The rich and the poor are nowise different when they meet in the grave, and both should be subject to the same regulations, for both are liable to the same changes in death, and have to pass through the same processes of decay, in order that the elements of their bodies may be restored to the living world, and may circulate in accordance with the law and economy of nature. We may endeavour to gratify our selfish feelings, and try to keep together the frail fabric of the cherished dead; we may swathe it in cerements, confine it in metal, or wood, or stone, and build it into vaults, and heap pyramids upon it; but all is in vain: the law of nature is, that it shall decay, and its elements pass again into the living world, and so circulate for ever. Our efforts, therefore, should be to expedite the processes of nature, and not to check them. There should be no burying in metal and building into vaults, but all our dead should find a common resting-place in the soil.

The superficial space which should be allotted to each grave should not be less than 20 feet. The largest coffin is about 6 feet long and 2 feet wide; and if such coffins, with a superficial area of 12 feet, were packed side by side, without earth between them, as many as 3620 could be disposed of in an acre; but such an arrangement would be manifestly improper, and therefore it has been decided that a sufficient layer of earth should be placed between the coffins, to enable the physical and chemical powers of the soil to perform their appointed duties. What the space for a coffin should be, is still a matter of uncertainty. It varies in different countries, from a superficial area of 30 to 90 feet.

Special
Hygiene.

The former will permit of 1452 graves in an acre, the latter of 484. In the resolutions which were issued from the Home Office, in accordance with the Burials Acts of from the 15th to the 19th of the present reign, it is ordered that the grave spaces for the burial of persons above 12 years of age shall be at least 9 feet by 4, and those for the burial of children under 12 years of age, 6 feet by 3. The former (36 square feet) will permit of 1210 burials in an acre; and the latter (18 square feet) 2420; the average of both being 27 square feet for each grave, or 1815 burials to the acre; but as the number of children buried is generally twice as great as that of adults, it would give an average of 24 square feet for each grave, or 2017 graves to an acre. Mr Chadwick says that the well-considered regulations for burials in towns give about 1452 common graves per acre. From all of which it may be concluded that a superficial space of about 30 square feet should be allotted to each grave. And it is also necessary that space should be allowed for the gravel walks in a cemetery, and for the ornamental culture of trees; for nothing is so salutary as the growth of vegetation in the organic soil of a burial-ground.

Another regulation from the Home Office is, that not less than 4 feet of earth shall be placed over the coffin, or rather that the coffin shall not be within 4 feet of the ordinary level of the ground, unless it contains the body of a child under 12 years of age, when it shall not be less than 3 feet below the level.

Lastly, it is recommended that only one body shall be buried in a grave at one time, unless the bodies be those of members of the same family; but although this regulation is a very salutary one, it is not observed in any cemetery or burial-ground in England, except in the burial-places belonging to the Jews, amongst whom the custom has prevailed from an early date.

The practice of burying the dead in vaults or catacombs or brick graves is fundamentally wrong, but still it prevails to a large extent in this and other countries; and the regulations which have been made in respect of it are, that the coffin shall be of lead, and that it shall be entombed in an air-tight manner in stone or brick-work, with proper cement. The space which is allotted to them is generally 9 feet by 5, or rather 9 feet by 4 and 9 feet by 6 alternately, and sometimes there is a channel along the head of the vault for ventilation. The notions which prevail in respect of the protective power of lead coffins and brick vaults are very erroneous. If the coffins are made so tight as to prevent the gradual escape of the pent-up gases, they will sooner or later explode; but commonly the lead is purposely left with small fissures and holes for the outlet of the gases. A time also comes when the outer wood coffin decays, and then the weight of the lead and its superincumbent tier of coffins flattens the metal case, and the organic remains are squeezed out, or are crushed by the heavy pressure. The lead also corrodes and becomes converted into white lead, by which means the coffins are pierced with myriads of small holes. These changes may be seen in almost every church vault in the kingdom, and they illustrate the absurdity and danger of such a mode of burial.

As to the time which should elapse before a grave is disturbed for a new tenant, it will vary with the character of the soil, the distance of the body from the surface, and the number of coffins in the grave. In a good soil, and under favourable circumstances, an adult coffin with its contents will have disappeared in 8 or 10 years; whereas in a clay or peaty soil it will remain for a century. It is generally assumed, that in a moderately good soil a period of 14 years is sufficient for the decay of an adult; that for young persons between the ages of 5 and 16 a period of 10 years is sufficient; and for infants under 5 years about half the time. But long before this the soft parts of the body will

Special
Hygiene.

have decomposed, and the skeleton alone will remain. This, however, at last decays, and crumbles into dust, which blends with the neighbouring soil. Not until this has taken place can it be said that the grave is ready for another tenant; for the return of dust to dust, and the total dissolution of the body, is alike required for the purposes of hygiene and for the respect which is due to piety and affection.

The delay which occurs in the burial of the dead has often suggested the necessity for providing some means for the preservation or custody of the body before interment, so as to prevent the mischief which is too often occasioned by putrefaction. In the houses of the poor this is especially needful, for it commonly happens that the dead are kept in the rooms which are occupied by the living; and many days may elapse before the necessary arrangements can be made for the burial: during the whole of this time, the occupants of the room are exposed to the foetid emanations from the putrid and sometimes infectious body. To guard against this, it has been proposed that there should be houses of reception for the dead, where the corpse might be detained in decent and respectful custody until the appointed time for its burial. These houses might also be used for the reception of bodies found dead in the public way; and means might be taken to prevent putrefaction until the period for interment. Provision has been made for this in most of the local sanitary acts, but it has not yet been put into practice, partly because of a fear that it would violate the feelings and domestic affections of the poor, and partly because it might be abused by those who are too eager to get rid of their dead; for if the body were once deposited in the reception-house, the further cost of its removal and interment might fall upon the local authorities. Altogether, the subject is beset with difficulties, but it is clearly one that requires consideration, for it might be developed so as to be of great advantage to the community.

The treatment of the existing evils which arise out of the present overcrowded state of the church vaults and graveyards is a matter of some importance. In the city of London, where this state of things has called for a remedy, it has been found that the most effectual way of dealing with the mischief is the following:—After a sanitary inspection by the government officer, an order in Council is issued for the final closing of the vaults. This is done under the supervision of the sanitary officer for the district; the coffins are arranged in order, and filled in with dry earth. They are covered to the depth of from 18 inches to 2 feet, with the same sort of earth; and over this is laid a stratum of coarsely-powdered vegetable charcoal to the depth of 3 or 4 inches. A ventilator or two should be carried from the vaults to the top of the church, and the ventilator need only be a pipe of about 4 inches in diameter. The vaults are then built in, and permanently closed with brick-work. In the case of the grave-yards, they are levelled and covered with a stratum of fresh earth, in which trees and shrubs are planted, and the whole is neatly laid out with grass. Vegetation acts as a salutary agent by absorbing the liquid humours from the soil, and by appropriating the organic vapours which may escape from the ground.

Disinfectants and Antiseptics.—It may not be out of place to refer in a very general way to the operation of these agents, and to their value as disinfectants; for putrefaction in one form or another is the chief cause of the unhealthiness of towns.

There are two classes of these correctives,—namely, those which check putrefaction by giving stability to the organic compound, and those which appropriate or absorb the foetid products. The first of these are properly called *antiseptics* or *antiputrescents*, and the second *deodorizers* or *disinfectants*. The antiseptics are common salt, vinegar,

sugar, alcohol, creosote, the empyreumatic oils of wood or peat or coal, and the metallic salts, as chloride of zinc, corrosive sublimate, sulphate of copper, muriate of iron, alum, &c. None of these agents entirely prevent putrefaction; they merely check it by combining with the animal matter, and forming compounds which are not prone to decay. They are employed in many operations of the arts, and in some cases are the popular means of preserving food.

The deodorizers act in one of two ways,—they either absorb and fix the foetid gases, or they utterly destroy them. Those which operate in the first way are the volatile acids, as vinegar, sulphurous acid, nitrous acid, and spirit of salts; the mineral compounds, as the salts of lead, iron, zinc, and manganese, all of which latter unite with ammonia and sulphuretted hydrogen, which are two of the most offensive constituents of almost every putrid vapour. Those which act in the second way are chlorine, hypochlorous acid, the manganates and permanganates of the alkalis, powdered charcoal, and fresh earth. The *modus operandi* of these is nearly always alike; they give oxygen to the putrid matter, and so destroy it. Where it is necessary to act upon organic vapours and putrid miasm, the volatile disinfectants, as chlorine or hypochlorous acid, should be employed; but where the putrid substance is in a solid or liquid form, the other agents may be used: of these, the manganate or permanganate of soda or potash (Condy's fluid) is the most rapid and safe; chloride of lime is also effective, and so is charcoal or dry earth, both of which absorb the foul gases, and bring them into chemical contact with atmospheric oxygen. Both of these agents therefore require free access of air. Practically, it will be found that Condy's fluid acts most freely on liquid products: it disinfects sewage, putrid water, and foul sores, almost immediately; solid substances, as animal remains, and the semifluid matter of cesspools, are best treated with a layer of charcoal or dry earth. A good deodorizer for the preservation of dead bodies during the time which elapses before burial can take place, is sawdust charged with a solution of sulphate of zinc and dried; it may be scented with a little camphor, to take off the cadaverous smell. Game also may be packed in it, when it is to be sent to a distance; and animal matters generally are well preserved by it. None of these agents, however, are applicable to the deodorization of sewage on a large scale, because of their cost. It has been calculated that the cheapest of them (chloride of lime), even when used in the proportions of only twelve grains per gallon, would cost nearly £240,000 per annum to deodorize the sewage of London. Quicklime, therefore, is generally employed in these cases; but it is not a perfect deodorizer, for it merely absorbs the sulphuretted hydrogen of the putrid compound, and casts down a part of the organic matter which is in solution; but if the precipitate is not quickly removed from the supernatant fluid, it passes into a state of decomposition, which is not less offensive than the original sewage. At Leicester and Tottenham, this process is used on a rather large scale, and with some success in a sanitary point of view, but with none in a commercial.

Fire is a powerful and complete disinfectant: it is there used in many processes of the arts where offensive vapours are evolved.

There are many other practical questions which the limits of this article will not embrace, as the economy and adulteration of food, the purity of medicines, the action of poisons and antidotes, the specific and general causes of endemic diseases, the origin and spread of epidemics, the importance of quarantine, &c.; but the facts which have been discussed will illustrate the leading principles of hygiene, and will suggest the rules which should be adopted for the protection of life and the preservation of health. (E. L., H. L.)

Special
Hygiene.

San Jose
||
Sannazaro.

SAN JOSE, the capital of the republic of Costa Rica, in Central America, on the river Cartago, 248 miles W. by N. of Panama; N. Lat. 9. 46., W. Long. 84. It is quite a modern town, and though the seat of the government, legislature, and law courts, and containing a cathedral and episcopal palace, has few remarkable buildings. There is here a large tobacco factory; and an active trade is carried on. Pop. 30 000.

SAN-JUAN-DE-LA-FRONTIERA. See **PLATA, LA.**

SAN LUCAR, a town of Spain in the province and 17 miles N. of Cadiz, in a bare, sandy, undulating country, on the left bank of the Guadalquivir, not far from its mouth. It stands partly on the flat bank of the river, and partly on the rising ground behind; its white glittering houses rising one above the other, up to an old Moorish castle on the summit. There are here 3 churches, 4 hospitals, one of them founded by Henry VIII. for English sailors, and the deserted buildings of several suppressed convents. The place is, however, dull and lifeless; having fallen off very much from its ancient commercial importance. It is now chiefly dependent on the wine trade, and is the mart of the inferior vintages sent to England as sherry. Many of the people are also employed in agriculture and fishing. The climate is hot, but not unhealthy. It was from San Lucar, in 1519, that the first voyage round the globe was begun by Magellan, who never returned, having been slain by the savages of the Philippines. Pop. 16,861.

SAN LUIS. See **PLATA, LA.**

SAN LUIS POTOSI. See **MEXICO**.

SAN LUSSURGHI, a town of the Island of Sardinia, in the division of Sassari, in a valley inclosed by mountains, 8 miles W.S.W. of Cagliari. Its narrow winding streets are lined with good houses; and there are several churches, a convent, and a school. Woollen and linen cloth are manufactured; and there is some trade in cattle, wool, &c. Pop. 4460.

SAN MARINO. See **MARINO, SAN.**

SAN MICHELI, **MICHELE**, an Italian architect of considerable celebrity, was born at Verona in 1484. He acquired his art under the eye of his father Giovanni and his uncle Bartolomeo, who were both architects of distinction. The ancient amphitheatre of his native town was a constant object of interest for the young architect, and his future designs are much indebted for their massive rusticated work to this period of youthful study. He went to Rome about 1500, where he was fortunate enough to gain the intimacy of all the famous artists of the day, Bramante, Michael Angelo, and the Sangalli. While in the ecclesiastical states, he constructed many buildings of celebrity, among others the cathedral of Montefiascone. On his return to the Venetian Republic, in 1525, he was engaged in erecting the new fortifications of Verona. Here he introduced, for the first time, the use of triangular and heptangular bastions, since so much employed by military engineers. He was subsequently engaged in fortifying many places in Cyprus, Candia, Istria, and Dalmatia, some of which were confided to his nephew, Gian-Girolamo. Both uncle and nephew had pressing offers from Francis I. and the Emperor Charles V. to enter their service, but to all such flattering proposals they gave an emphatic refusal. The palazzi or mansion-houses of San Micheli are many of them not to be imitated, abounding, as they do, in irregularities of design, and in a curious mixture of highly ornamented work, with decidedly bald construction. San Micheli enjoyed an honourable old age, and died in 1559 in his seventy-fifth year.

SAN MIGUEL, a town of Central America, in the republic and 45 miles E.S.E. of San Salvador, on the navigable river Lempa, 20 miles above its mouth in the Pacific. It contains a church and convents; and the people are mostly employed in agriculture. Pop. 6000.

SANNAZARO, JACOPO, an elegant Italian poet, was

born at Naples on the 28th of July 1458, of a noble family of Spanish origin, who dwelt at San Nazaro, a mansion-house situated near Pavia. He began his studies at Naples, under Giuniano Maggio, but was very early interrupted by an unfortunate love affair, which drove him to travel. Some say he went to France, where he wrote his first poem, *Arcadia*, in 1502, an Italian pastoral, in which he describes, in alternate prose and verse, the scenes and occupations of pastoral life, intermingling them with adventures which really occurred to himself. The poem has been greatly admired for the elegance and purity of its diction; and the author has been generally ranked with the best poets of his country. The success of this work was early extended to Spain. Ticknor, in his *History of Spanish Literature*, vol. iii., p. 38, says, that "Spain was the first foreign country where the *Arcadia* was imitated, and was afterwards the only one where such works appeared in large numbers, and established a lasting influence." In 1526 appeared the work which gained him the name of the "Christian Virgil," *De Partu Virginis*. This poem, which was written in Latin, was much applauded, and the author gained the sanction of Popes Leo X. and of Clement VII. to his production. This work, and his *Sonetti e Canzoni*, 1530, gained for their author a very wide reputation. He received great honours on his return to Naples from King Ferdinand I., and subsequently from Frederick, the last Neapolitan king, who assigned him a residence on the beautiful slope of Mont Posilipo. Sannazaro accompanied the latter king in his exile to France, where he remained while that monarch lived. On his return to Italy, it is said, he was told one day that the Prince of Orange had been slain in battle, who, among other indignities, had recently demolished the poet's country-house; when Sannazaro called out, "I shall die contented since Mars has punished this barbarous enemy of the Muses." He died soon after, on the 27th of April 1530.

SAN PAULO, a province of Brazil, lying between S. Lat. 20. and 24. 30., W. Long. 44. 30. and 53; bounded on the N. by the provinces of Goyaz and Minas Geraes, N.E. by that of Rio de Janeiro, S.E. by the Atlantic, S. by Curitiba, and W. by Parana. Area, 170,615 square miles. The coast line is about 400 miles in length, and stretches from N.W. to S.E.; along the shore is a narrow strip of low land, and beyond it rises a ridge of mountains extending in a parallel direction. These form the watershed of the province, dividing it into two very unequal portions; the rivers of the eastern part flowing directly into the Atlantic, and those on the other side reaching the same destination through the Parana, which forms part of the northern and the whole of the western boundary of the province. The mountains are for the most part of granite formation, and their upper parts are covered with dense forests of valuable timber, especially cedar and pine. Their lower slopes, and the country as far as the Parana, are almost all exceedingly fertile. The principal affluent of the Parana in this province is the Tiete, which flows from east to west very nearly in the centre of the country. Grain, rice, and manise, are the principal crops raised in the interior. Along the coast, tobacco, sugar, and cotton are cultivated. Horses and cattle are reared in great numbers on the tablelands in the central parts of the province. The extreme portion is still occupied by aboriginal tribes. There are several seaports along the coast, by means of which a considerable trade is carried on with Rio Janeiro. San Paulo is divided into 7 comarcas; and represented in the legislature of Brazil by four senators and nine deputies. Pop. (1856) 500,000.

SAN PAULO, the capital of the above province, on a lofty uneven piece of ground, between two small streams, 32 miles from the sea, and 220 miles W. by S. of Rio de Janeiro. It has narrow, well-paved streets, lined with

San Paulo.

Sanquhar earthen tiled houses, generally two storeys high, and frequently provided with balconies. There are here a cathedral of large size but no great beauty, 7 other churches, 5 convents, a splendid episcopal palace, theatre, public library, several schools, an imperial manufactory of arms, woollen and cotton factories, and gold refineries. It is the central point of the Brazilian mining operations; and in the vicinity are valuable gold mines. San Paulo is the seat of the provincial assembly, courts of law, and public offices. Pop. 25,000.

San Salvador.

SANQUHAR, a royal and parliamentary burgh of Scotland, in Dumfriesshire, near the left bank of the Nith, 27 miles N.W. of Dumfries, and 56 S.E. of Glasgow. It has one long principal street, neither very regular nor clean. The chief buildings are the town-hall, parish church, Free Church, 2 United Presbyterian, and a Reformed Presbyterian Church, several schools, &c. Weaving, muslin-sewing, and carpet-making are the chief employments of the people. The burgh is governed by a provost and nine councillors; and represented in Parliament by one member. Pop. (1851) of the parish, 4071; of the parliamentary burgh, 2381; of the town, 1884.

SAN SALVADOR, a state of Central America, lying between N. Lat. 13. 7. and 14. 24., W. Long. 87. 37. and 90. 2., bounded on the N. and E. by Honduras, S. by the Pacific, and W. by Guatemala. Its length is 165 miles, its mean breadth 69, and its area 11,392 square miles. There are two lines of water-parting in San Salvador, one extending from E. to W. parallel to the Pacific coast, separating the waters that flow directly into the Pacific from the affluents of the Lempa; and the other further inland, having a parallel direction, with the Sumpul and Torola on its N. side, and the Lempa (except for a short distance where it pierces through the chain) on the S. This watershed forms the chain of the *Cordilleras*, but consists rather of isolated hills, or groups of hills with their offshoots, than of a continuous range. Along the shore of the Pacific stretches a low tract of rich alluvial land, varying from 10 to 20 miles in breadth. Beyond this the ground rises abruptly to the height of 2000 feet, forming a broad tableland, above which tower many lofty volcanic peaks. From the highest portion, which forms the lower watershed of San Salvador and the southern edge of this plateau, to the chain of the *Cordilleras*, stretches the broad valley of the Lempa, about 100 miles in length, and from 20 to 30 across. The ground slopes very gradually from the south for some distance, and then descends abruptly to the proper valley of the river; on the other side it rises with a more uniform ascent, though broken and rugged, to the foot of the mountains that form the upper watershed of the country, and tower over it at a height of 6000 or 8000 feet. The Lempa rises in the N.W. of the state, and flows for the most part of its course towards the S.E., then turns suddenly to the S., and falls into the Pacific. The whole length of its course is 150 miles, but it is navigable only for 27 miles. The chief affluents of this river are the Sumpul, which forms the northern boundary of the state throughout its course, and the Torola, both from the left. Besides the Lempa, San Salvador is watered by the Rio Paza in the west, separating it from Guatemala, and by the San Miguel in the E. There are two lakes of some size in the country, that of Guija in the N.W., discharging its waters by the Quesalapa into the Lempa, and that of Ilopango, near the centre. The latter of these, as well as many others of inferior size, is of volcanic origin. Indeed the whole of the country is remarkable for its volcanic character, and for the number of burning mountains, both active and extinct, which it contains. A line of eleven great volcanoes extends along the crest of the table-land, between the shore and the Lempa. These are in their order, beginning at the N.W. extremity, **Apeneca, Santa Anna, Izalco, San Salvador, San Vicente,**

Tecapa, Usulután, Sacatecoluca, Chinemeca, San Miguel, and Conchagua. Of these only Izalco and San Miguel are now active. The former has been entirely formed, since the discovery of the country, from the stones and ashes emitted by the crater, which first opened in 1770. Its height is now about 2500 feet. San Miguel is a cone about 6000 feet above the plain, its lower portion covered with dark green forests, and the lighter verdure of the meadows above them; its summit tinted by the dark brown *scoriae* and the silvery hue of the ashes from the crater, and surmounted by clouds of smoke ceaselessly rolling up from the interior. Probably no region in the world of equal extent contains so many volcanoes, or traces of volcanic action, as this little state, where for days the traveller's road lies over beds of lava and similar substances. A consequence of this is the great fertility of the soil, and the luxuriant vegetation that covers the mountains up to their very summits. The entire soil of San Salvador is either volcanic or alluvial. The ground of the latter sort has been gradually formed, in the lapse of ages, from the ashes and stones ejected by volcanoes now extinct. It occurs for the most part in small patches, scattered over different parts of the country; the most extensive tract of alluvial ground being in the district of Gotera, in the department of San Miguel. In other places, the action of volcanic forces is most strikingly apparent, from the confused assemblage of abrupt cliffs, deep ravines, mountains, valleys, and plains indiscriminately mixed together.

The country is essentially an agricultural one, and well cultivated, the low land yielding tropical produce, and the upper regions the crops of northern climes. Indigo is the plant raised in the largest quantities. Sugar, cacao, coffee, and tobacco are also grown. Almost all the land is cultivated, very little remains unclaimed, and there are few large estates belonging to individuals. The rural population consists mostly of Indians, and the lands which they have been allowed to retain have tended to their encouragement in industrious habits. For the most part they live in villages, which stud the country in great numbers; going in the morning to and returning at night from their little patches of ground in the vicinity. Roads have been constructed throughout the most of the country. The mineral resources of San Salvador include the silver mines of Tabanco in the N.E. of the state, which are easily worked, and yield from 47 to 2537 oz. per ton; and the iron mines of Petapa in the W. It is also believed that extensive beds of coal exist throughout the valley of the Lempa. A certain part of the coast of San Salvador, about 50 miles in length by 20 or 25 in breadth, between La Libertad and Acajutla, is called the Balsam Coast, because it produces what is erroneously called the balsam of Peru. This is obtained from the juice of a tree; the whole region as far inland as the mountains being covered with dense forests occupied by Indians, who make their living by selling this balsam and planks of cedar-wood.

The seaports of the country are La Union, on the Gulf of Fonseca; Libertad and Acajutla further west, along the shore. Of these, the first only is properly a harbour, the others being merely open roadsteads. The number of vessels that entered and cleared in 1858 was 156 each way; tonnage, 55,163. In 1857 the total value of the exports was £260,820, being an increase of £37,233 over the preceding year; and the imports amounted in value to £172,021, showing a decrease of £37,323. The value of the chief articles exported was:—Indigo, £230,751; sugar, £14,011; hides, £12,961; tobacco, £3920; balsam, £1437. Very few manufactures are carried on here, and these are chiefly articles for domestic use, such as coarse cotton cloth and hardware. The great majority of the people are Indians, belonging, in all probability, to the Nahual or Aztec race, who inhabited Mexico before the Spanish invasion. Their language is very similar to that

San Salvador.

San Salvador. spoken by the natives of Mexico, and they seem from the ancient traditions to have come from Nicaragua, which was occupied by an offshoot of the Nahuatl race. In most parts of the country they have become assimilated, more or less, to the Spaniards, and have adopted their manners, but in the Balsam Coast they have preserved the purity of their blood and language, as well as in some measure the mode of living of their ancestors. This part of the country is very difficult of access, being traversed only by intricate footpaths, and they have a great dislike to the intrusion of white men. In this district the ancient language is retained, which has almost entirely fallen out of use in other parts of the country. The towns in San Salvador are generally inhabited by white men and those of mixed blood (*ladinos*), the former being generally merchants or proprietors of estates (*haciendas*), and the latter employed in mechanical pursuits. The Indians in the villages and country districts are engaged in agricultural labour.

The government of the country is republican: the executive power is in the hands of a president, elected for two years; and the legislature consists of a chamber of twenty-five members. The army consists of 1000 regular troops, all infantry, and a militia of 4000 men, infantry, cavalry, and artillery. The public revenue in 1855 amounted in all to L.89,360; and in 1856 to L.105,520. The provisory seat of the government is Cojutepec; the former capital, San Salvador, having been destroyed by an earthquake on the night of the 16th of April 1854. It was a place of 25,000 inhabitants, and had a very picturesque and beautiful appearance, being planted in many parts with palm-trees and shaded with evergreens. The buildings were generally low, but there was a fine cathedral, a large university, and other handsome edifices. But the whole was destroyed in a few moments. It was the evening of Easter Sunday, about half-past nine, when the inhabitants were first warned of their danger by a slight shock, and at ten minutes to eleven the ground began to heave and tremble with such force that in ten seconds the entire city was a mass of ruins. Churches and houses fell with a tremendous crash to the ground; terror and dismay seized all the inhabitants that death had not overtaken; and a dense black cloud of dust hung over the whole scene. The loss of life, however, was afterwards ascertained to be less than was at first supposed.

The first European who invaded San Salvador was Alvarado, one of the officers under Cortez, in the conquest of Mexico. After having conquered the country now called Guatemala, he was informed of the existence of a powerful nation to the south-east, which he resolved also to conquer. He met with an obstinate resistance, but succeeded in penetrating as far as the capital, Cuscatlan, where, however, he only remained a few days. The country was then one of the best peopled in America, and contained many large towns as well built as those of Mexico. For a long time the inhabitants resisted the invaders; and it was only by the advantages of cavalry and fire-arms that the conquest was consummated. The country afterwards formed part of the general captaincy of Guatemala, and remained under the Spanish government till 1821, when, by a bloodless revolution, the province regained its independence. Until 1823 San Salvador, along with the other parts of the Spanish Guatemala, was united to Mexico; but in that year a confederation was formed by the five states of Guatemala, Honduras, San Salvador, Nicaragua, and Costa Rica, under the name of the Confederation of Central America. This arrangement continued until 1840, after which the component parts of the confederation became entirely independent, as they have since continued to be. San Salvador is the best peopled, as well as the first in industry and commerce, of all the states of Central America, and indeed of all Spanish America; and the people are superior in intelligence, industry, and enterprise to those of the neigh-

bouring countries. It is divided into six departments, as follows:—

	Pop.		Pop.
San Miguel.....	80,000	Sonsonate	75,000
San Vicente.....	56,000	La Paz	28,000
San Salvador.....	80,000	Cuscatlan	75,000
Total	394,000		

Sanson.

But more recent returns bring the entire population to 580,000.

SANSANDING, a town of north-western Africa, in the kingdom of Bambara, on the right bank of the Joliba or Quorra, 20 miles N.E. of Sego, N. Lat. 13. 40., W. Long. 6. 9. It is an extensive town, and has an active trade with Timbuctoo, carried on by means of the river, which is navigable between these two places. Salt from the Sahara, coral and beads from the Mediterranean, are all conveyed to western Soodan through this town, and exchanged for gold, ivory, slaves, wax, honey, &c. Pop. 11,000.

SANSCRIT. See LANGUAGE and PHILOLOGY.

SAN SEBASTIAN, a seaport of Spain, capital of Guipuzcoa, one of the Basque provinces, on the shore of the Bay of Biscay, 42 miles N.N.W. of Pampeluna. It occupies a narrow isthmus, terminated towards the north by a conical rock 400 feet high, called Urgull or Orgollo, and flanked on one side by the river Urumea, which is crossed by a bridge, and on the other by a bay, which forms the harbour. The summit of the hill is occupied by a fort, with five fronts, and the landward side of the town is defended by solid ramparts, with a bastion in the centre. The houses are almost all modern, built uniformly in straight streets and regular squares, so as to present an appearance quite unlike most Spanish towns. There are two large irregular churches, a handsome court-house, a nunnery, theatre, hospitals, barracks, &c. The manufactures of the place are insignificant; and the harbour is small, and not easily accessible, though well protected by a mole and small island. There is a considerable trade in English and French goods, corn and other articles being exported. From its position and strength, San Sebastian has been long a place of much importance, and has sustained several sieges. The most memorable of these was in 1813, when the British, under Wellington, took it by storm. Pop. 10,036.

SAN SEVERO, a town of Naples, capital of a district in the province of Capitanata, on the northern edge of the *Tavoliere di Puglia*, or great pastoral plain of Apulia, at the foot of Monte Gargano, 20 miles N. by W. of Foggia. It is walled, but outside of the fortifications a new town and extensive suburbs have sprung up. In this portion stand many handsome residences of the more wealthy citizens. The inhabitants in 1799 made a gallant but vain resistance to the French under Duhesme, in revenge for which an indiscriminate slaughter was begun, and the town was only saved from total destruction by the heroism of the women, who threw themselves between the victorious soldiery and their victims. Pop. 19,000.

SANSON, NICOLAS, said to be the creator of French geography, was born at Abbeville, December the 20th, 1600. He was educated at the Jesuits' College at Amiens, and afterwards devoted much of his attention to the study of geography, a pursuit of which his father is said to have been particularly fond. At the age of sixteen, young Sanson laid down a map of ancient Gaul, said to be superior to those of Ortelius and Mercator. Having married early, he applied himself to commerce; but, devoting too much attention to his favourite pursuits, his affairs soon became embarrassed, and he gave up his ledgers for ever. Visiting Paris in 1627, and taking with him his map of Gaul, he had the good fortune to attract the notice of Louis XIII., who not only took lessons from him in geography, but made him engineer of Picardy. His duties in the latter

Sansovino
||
Santa
Catharina

position did not interfere with his zeal for geography. He settled in Paris in 1640, where he published numerous maps, together with illustrative volumes. Sanson was made geographer to the king, received a royal pension, and was chosen a councillor of state; but did not assume the rank, lest, it is said, his children should abandon the favourite pursuit of their father. His death, which happened at Paris on July 7, 1667, was induced by the incessant labours to which his devotion to geographical science subjected him.

Sanson, although a zealous geographer, is said by Languerue to have constructed very indifferent maps, and it is well known he was but an indifferent critic; but he had the merit of originating the art, and left subsequent geographers to carry out that which he had so well begun.

SANSOVINO, JACOPO TATTI, was a distinguished Italian sculptor and architect, and was born at Florence in the month of January 1477, and not in 1479, as Temanza would have it. Tatti was born in the same street (Via Santa Maria) with Michael Angelo, who was then rising to the zenith of his fame; and it is said the mother of the youth, whom he strongly resembled, caused him to be secretly taught drawing, for which he had shown great aptitude, with the ultimate design that her son should rival the glory of his townsman, Michael Angelo. He assumed the name of *Sansovino*, out of compliment to his generous master, Andrea Contucci of Monte Sansovino, with whom he had learned the rudiments of his art. He seems likewise to have profited much by a very close intimacy with Andrea del Sarto. Sansovino becoming acquainted with Guiliano Sangallo, the architect, this artist took Sansovino to Rome, where he procured for him the friendship of Bramante and of Pope Julius II. On his return to Florence, he executed his celebrated statue of Bacchus, which was destroyed by fire in 1762. During his residence in his native city he tried his hand at architecture, and designed several triumphal arches of great beauty, to celebrate the public entry of Leo X. in 1515. He returned to Rome, only to leave it in 1527, when it was taken and sacked by the imperial troops of Charles V. of Spain. Having sought Venice on his way to France, whither he had been solicited by the court, he was induced to take up his abode in that city, where he afterwards spent his life in the enjoyment of much honour and fame. He began his labours in Venice by repairing the dome of St Mark's, and subsequently erected numerous structures for private individuals and for the Venetian republic. Among his works of this class are the unrivalled Library, opposite the Public Palace; La Zecca or the Mint (his finest work), the Loggia del Campanile, San Geminiano, the Palazzo Cornaro à San Maurizio (one of this artist's most excellent works), San Giorgio de' Greci, La Scuola della Misericordia, San Francesco della Vigna, Palazzo Delfino, Fabbriche Nuove di Rialto, &c. Sansovino did not neglect his sculpture while he raised his reputation as an architect. Three of the most beautiful statues in Venice, according to Vasari, a Laocoon, a Venus, and a Madonna surrounded by angels, are from Sansovino's hand. In addition to these, he executed two colossal figures of Mars and Neptune, which adorn the Giants' Staircase, in the ducal palace, when considerably upwards of seventy years. "In his draperies," says Vasari, "his children, and the expression which he gave to his women, Jacopo never had an equal." He died at the ripe old age of ninety-three, on the 2d of November 1570.

SANTA ANNA, a town in the republic of San Salvador, in the department and 12 miles N.E. of Sonsonate. It has many distilleries, and a large trade in indigo, tobacco, and sugar, which are raised in the vicinity. Pop. estimated at 10,000.

SANTA CATHARINA, a maritime province of Brazil, lying between S. Lat. 26. and 29. 30., W. Long. 48. 30. and 52., bounded on the E. by the Atlantic, N.W.

VOL. XIX.

Santa
Cruz
||
Santa
Marta.

by the province of Sao Paulo, S.W. by that of Rio Grande do Sul. Length from north to south about 230 miles; breadth varying from 60 to 200; area, 14,707 square miles. The coast is low, but the inland part of the province is hilly, being traversed by the mountain range of Santa Catharina, from which numerous offsets stretch towards the sea. Down the valleys thus formed flow many rivers, such as the Sao Francisco, Aracary, Tapeçu, Tijnea, and others, discharging their waters into the Atlantic; while on the other side of the mountain, the Uruguay, one of the affluents of the La Plata, has its source within the limits of this province. The soil is for the most part fertile, and the climate mild: and, owing to the variety of elevation in different parts of the country, the productions of European countries are raised here, as well as those of more tropical lands. The extensive forests of the country abound in valuable timber; but many of them are infested with wild animals, who dispute their possession with the native Indian tribes. Indigo and cochineal grow without culture. Sugar, rice, millet, beans, onions, and garlic, are used in large quantities, and exported to Rio Janeiro. Some of the rivers are navigable, and there are a few good harbours along the coast; but the principal is that formed by the island of Santa Catharina. This island, upwards of 30 miles in length, by about 10 in breadth, is separated from the mainland by a strait about 7 miles broad at the widest, but narrowing at one place to less than a mile across. This narrow part is formed by two projecting capes, which thus divide the strait into two safe and capacious harbours. The surface of the island is undulating, and well wooded; it has many fine lakes and rivers, and enjoys a mild and salubrious climate. The capital of the province, Nossa Senhora do Desterro, stands on the west coast of the island, which contains also some of the other principal towns. The province of Santa Catharina returns one senator and one deputy to the Legislative Assembly of Brazil. Pop. (1856) 105,000.

SANTA CRUZ. See CANARY ISLANDS.

SANTA CRUZ DE LA SIERRA, the largest and most easterly department of Bolivia, bounded on the N. by that of Beni and by Brazil, E. by Brazil and Paraguay, S. by the Argentine Confederation, and W. by Tarija, Chuquisaca, and Cochabamba. It lies between S. Lat. 15. and 22., W. Long. 57. and 65., and has an area of 136,235 square miles. The surface is level or undulating, and covered with extensive and hitherto unexplored forests. Here occurs the watershed between the affluents of the Amazon and those of the La Plata; the Rio Grande and Rio Blanco belonging to the former, and the Pilcomayo and Paraguay to the latter, watering the department. The last-mentioned river, however, only forms the eastern boundary of the country for some distance. Minerals are believed to exist in large quantities here, and the soil produces sugar, coffee, cacao, rice, cotton, indigo, &c. The greater part of Santa Cruz is still occupied by native tribes of Indians, and very few settlements have been made. Pop. 69,000.

SANTA FÉ, a department of the Argentine Confederation. See PLATA, I.A.

SANTA FÉ, the capital of the territory of New Mexico, in the United States of North America, in a wide plain, barren and sandy, surrounded by lofty mountains, about 20 miles E. of the Rio Grande. The streets are narrow and crooked, and the houses, built of sun-dried bricks, have generally but one storey, and an open court in the middle. The most conspicuous buildings are two Roman Catholic churches, with spires. The inhabitants are mostly Spaniards and Indians. Santa Fé is a place of considerable trade. Pop. 7000.

SANTA MARTA, or MARTHA, a seaport of New Granada, capital of a province in the department of Magdalena, on the east shore of a bay of the same name, on the Caribbean Sea, 40 miles N.E. of the mouth of the Mag-

Santa
Maura
||
Santander.

dalena. It has many well-built houses, a cathedral, and a safe harbour, defended by a citadel and battery. Here are some of the most important mercantile houses in the country, and a company for the steam navigation of the Magdalena. The transit trade of the place is very considerable. Pop. 8000.

SANTA MAURA. See IONIAN ISLANDS and LEUCADIA.

SANTANDER, a province of Spain, bounded on the N. by the Bay of Biscay, E. by the province of Biscay, S. by that of Burgos, S.W. by Palencia, and W. by Oviedo. Area 3434 square miles. It is almost entirely occupied with lofty mountains, for the Cantabrian chain traverses the south of the province, and sends off numerous branches towards the sea. Between these there are deep narrow valleys and glens, watered by the rivers that take their rise in the mountains; such as the Deva, Nansa, Besaya, Miera, and others. The loftier regions of the province contain much fine pasture-ground, and are clothed with extensive forests, affording good timber for various purposes. The most prevalent tree in these woods is the lime; but oaks, firs, walnuts, chestnuts, plum-trees, fig-trees, and some apple-trees, are also grown in the province. Maize, wheat, wine of inferior quality, vegetables, and fruit, form the principal produce of the valleys; and maize bread is the chief article of food among the peasantry. Iron, argentiferous lead, and other metals, are obtained here; and there are quarries of limestone, marble, gypsum, and beds of potters' clay. Leather, woollen and cotton cloth, agricultural implements, and other articles, are manufactured; and many of the people live by fishing and fish-curing; but trade of all kinds is much impeded by the deficiency in the means of communication. The only important seaport in the province is Santander, the capital, through which the foreign trade is carried on. The people of the province are quiet, sober, and industrious, and education is more attended to here than in most parts of Spain. Pop. (1857) 232,523.

SANTANDER, the capital of the above province, on the shore of the Bay of Biscay, at the mouth of the rivers Cubas and Fijeros, 85 miles N. of Burgos, and 207 N. of Madrid. It stands on the north side of a large open harbour, and is sheltered towards the north by a small ridge of hills, beginning at the entrance of the harbour, and stretching westwards. The town was once surrounded by walls, of which scarcely a trace now remains, as the buildings have extended far beyond its original limits. There is a cathedral here, not very remarkable for architectural merit, and disfigured by a tasteless modern cupola; several other churches, hospitals, a town-hall, theatre, custom-house, college, and several schools. A cigar manufactory occupies the precincts of a suppressed nunnery; tanneries, breweries, sugar-houses, candle factories, cooperages, &c., are also among the manufactories of the place. The harbour is large, deep, and safe, affording good anchorage, and easy of access. There are fine quays, always busy and crowded. The number of vessels that entered in 1856 was 447, tonnage, 51,788: that of those that cleared in the same year 408; tonnage, 56,375. Santander carries on a considerable trade, almost entirely with Cuba, to which island it exports the flour of Castille, receiving in return sugar, coffee, and rum. Cacao is also brought from La Guayra, and small quantities of fish from Norway, Shetland, and Newfoundland, in exchange for timber, hides, oil, and rice from Spain. The total value of the imports in 1856 was L.976,611, and that of the exports L.363,353. The custom returns for 1855 amounted to L.184,047. Santander is joined by railway with Alar del Rey, about 70 miles off in the interior, and steamers ply regularly between this port and Nantes, Bayonne, Liverpool, and Hamburg. Several improvements are being carried out in the harbour, by increasing its

depth, and erecting a mole and a lighthouse. Santander (called by the Romans *Portus Blendium*) was, at an early period, an important seaport; but afterwards fell into decay, and only recovered its position after the discovery of America, when it was licensed to trade with that continent. Charles V. landed here in 1522, to take possession of the Spanish crown; and Charles I. of England re-embarked here in 1623 after his visit to Spain. Pop. about 20,000.

SANTAREM, a town of Portugal, capital of a district of the same name, in the province of Estremadura, on a rocky hill on the right bank of the Tagus, 50 miles N.N.E. of Lisbon. It is in general well built, although many of its splendid mansions are in a ruinous condition. Some remains still exist of the ancient walls, which in the time of the Moors gave the place such strength, that it was considered almost impregnable. The town is remarkable for the number and antiquity of its ecclesiastical buildings. One edifice, originally a mosque, and thereafter a church, is now used as a theatre, and much defaced. Besides churches and convents, the town contains also schools and hospitals. The surrounding country is very rich, and Santarem carries on an active trade with Lisbon by means of the river, especially in corn, wine, and oil. Pop. 8000.

SANTEUL, JEAN BAPTISTE DE, an excellent Latin poet, was born at Paris in the year 1630. Having finished his studies, he applied himself entirely to poetry, and celebrated in his verse the praises of several great men, by which he acquired universal applause. He enriched Paris with a great number of inscriptions, which are to be seen on the public fountains and monuments of the city. At length, some new hymns being required for the Breviary of Paris, Claude Santeul his brother, and M. Bossuet, persuaded him to undertake that work. Santeul was intimate with all the learned men of his time, and had as his admirers the two Princes of Condé, father and son, from whom he frequently received favours. Louis XIV. also gave him a proof of his esteem by bestowing upon him a pension. He attended the Duke of Bourbon to Dijon, and died there in 1697, as he was preparing to return to Paris. Besides his Latin hymns, he wrote a great number of Latin poems, which have all the marks of genius discoverable in the works of true poets. The best collected edition of the *Œuvres* of Santeul is that in 3 vols., Paris, 1729.

SANTIAGO, the largest of the Cape Verd Islands, and in position one of the most southerly of the group, N. Lat. 14. 54., W. Long. 23. 40. Length 35 miles, breadth 12; area 360 square miles. In its general character it is mountainous, being traversed by a ridge which divides the two *conselhos* of Villa Praia and Santa Catarina, and attains near the centre, in a cone-shaped summit called Antonia, the height of 4,500 feet above the sea. There are, however, a number of fertile and well-watered valleys which stretch towards the coasts, and open out into wide plains and gentle slopes. The geological formation of the mountains is basaltic, with extensive layers of clay, and deposits of chalk and lava. The valleys are mostly occupied with gardens and plantations of coffee and sugar, separated by *purgueira* hedges. In the more level parts, the better land is planted with cotton, anise, and *purgueira*, whose oil forms an important article of export, while the inferior soil is used for pasture; but no trees can be grown on account of the violent hurricanes to which the island is liable. The average produce of the island is 542 pipes of brandy, 97,000 lbs. of sugar, 14,800 qrs. of maize, about as much of beans, and 22,200 qrs. of *purgueira* seed. Santiago has seven harbours for large vessels, the largest, deepest, and safest of which is Praia, on the south coast. It is divided into two *conselhos* and eleven parishes, and has a population of 31,103, of whom 28,137 are free and 2866 slaves.

Santiago.

Santiago
de Chili.

SANTIAGO DE CHILI, the capital of the republic of Chili, and of the province of the same name, on the Mapocho, an affluent of the Maypu, 90 miles E.S.E. of Valdivia, at an elevation of 1836 feet above the level of the sea, calculated from the marble fountain in the *plaza*. S. Lat. 33. 26., W. Long. 70. 38. The plain in which it stands is too lofty to exhibit much natural verdure or luxuriant vegetation, except along the banks of the rivers and artificial canals which water the soil. Still the situation of the city is exceedingly fine, and its scenery very beautiful; the majestic ridge of the Andes towers with its snowy summits to the east, while a lower ridge bounds the plain on the west. Careful irrigation has converted large portions of this plain into a very rich expanse, productive especially of wheat, which yields on an average twentyfold. The climate is salubrious, the thermometer ranging between 70° and 75°; and there is no rain and little wind. The rate of mortality fluctuates between 9 and 11 per cent. Among children, however, from 1 to 7 years old, the mortality is much greater, since of these it may be considered that 2590 die annually; while of adults from 25 to 35, the number of deaths is only about 148. This circumstance is to be ascribed to the abundance of unripe and unwholesome fruit, which is greedily devoured, especially by the poorer children. The annual number of births averages about 2300 males and 2690 females. Of the former rather more than half, and of the latter about the half, die. Santiago, like all other Spanish-American cities, is laid out in squares; the streets, which are broad, but not very well paved, crossing each other at right angles. A beautiful avenue, consisting of four rows of stately poplars, with streams of water between them, and a beautiful fountain at one end, divides the city into two parts. The private houses were for a long time low and mean-looking; but within the last ten years great and rapid improvements have been made in the style of house architecture. There are now many handsomely-built and equally well-furnished mansions, most of which have cost not less than L.20,000 for their erection. Near the centre of the town is the great square or *plaza*, with a marble fountain in the middle. Round it stand some of the public buildings of the city. These have in general nothing remarkable about them. The most noteworthy are the mint, the *Camara de Diputados*, or hall of deputies, and the theatre, which accommodates 1500 persons. The churches are very plain; the best are the *Compañia*, the cathedral, and Santo Domingo. Santiago possesses a national public library, containing 23,000 volumes, and a library of the tribunals with 1600 volumes; a museum; an observatory; a university; two hospitals; and a proportionate number of asylums, convents, nunneries, and schools of various descriptions. There are no manufactories worth noticing; a pottery has been lately established, and is now struggling into existence; and a coarse cloth factory has long existed in a very languishing condition. The city is lighted with gas; and an attempt has been made to introduce water in pipes, but this has been as yet only partially successful, and the inhabitants still receive their water in barrels brought on the backs of horses from the public fountains. Tolerable carriage-roads connect Santiago with the coast, and with the far-off northern and southern extremities of the wide-spread republic of which it is the capital; while at present a railroad to Valparaiso and another to Talca are in progress, the former connecting it with the vast Pacific, and the latter with a long series of agricultural provinces. There is a considerable trade carried on, chiefly through Valparaiso. Fruit, hides, salt beef, and the produce of the mines are exported; while sugar, cacao, and other articles are imported from Peru and Central America. Some commercial intercourse also subsists between Santiago and Mendoza, on the other side of the Andes, across which

there are here two passes, lofty but practicable, for mules. The city was founded by Pedro de Valdivia, on the 24th of February 1541, on property belonging to the Cacique Huelen-Guala, surrounding the little hill or rather rock of Huelen, now called Santa Lucia. This hill is now crowned with a fort, which is frequently visited by strangers for the sake of the fine view it commands. Valdivia portioned out the city into lots, in squares of 150 Spanish or 138 English feet, which he divided into fourths, called *solares*, or building sites. Each of his followers received one of these, on which he built his wooden, straw-thatched house. Each received likewise a piece of enclosed land, for the cultivation of wheat and vegetables. Thus the city rose, and soon became rich and populous. But many barriers were opposed to the advancement of its prosperity by the restrictive policy of Spain, as long as Chili remained subject to that country. When the colonies achieved their independence, Santiago sprang into new life and activity, and made such rapid progress in size, wealth, and civilization, that it may now be ranked among the most flourishing and important cities of South America. Besides natives, it is inhabited in a large proportion by foreigners. Of these the most numerous are the Germans; then Americans and English conjointly, who, till the railway and gas-works were commenced, were the scarcest; next to them, French and Italians. The population is 107,000, in the proportion of 1 unmarried man to 3 unmarried women; 14,420 married men to 14,570 married women.—The province of Santiago comprises the departments of Santiago, Victoria, Melipilla, and Rancagua, and is bounded on the north by the provinces of Aconcagua and Valparaiso, south by that of Colchagua, while the Argentine Republic lies to the east and the Pacific to the west. Its length is about 120, and its breadth 114 miles. Along its eastern border stretch the Andes from north to south; and in this part of the range stands their highest summit within the dominions of Chili, Tupungato, 22,015 feet high; for Aconcagua, which attains the height of 22,800 feet, belongs to the Argentine Republic. Between the mountains and the sea, this province contains some of the richest valleys in Chili. It is well watered, and enjoys a fine climate. Santiago is consequently almost exclusively an agricultural country, and its principal production is grain; but it also yields silver and copper to a considerable value. The great mass of the people are farm-labourers, of whom there are 24,000; then farmers, of whom there are 11,400; of sempstresses, there are 10,011; of washerwomen, 4585; of cooks (chiefly women), 4206; of spinners, 5493; of servants, 9618; of shopkeepers, 2501; shoemakers, 4204; weavers (chiefly women), 1777; miners, 1036; priests, 321; teachers, 170; doctors (M.D.), 39; advocates, 150; wet nurses, 350; dentists, 5; dressmakers, 22; tailors, 870; butchers, 80; bakers, 600; jewellers, 35. The whole population amounts to 280,000, of whom 16,000 males and 13,000 females are able to read and write.

SANTIAGO DE COMPOSTELLA, a town of Spain, Galicia, in the province and 32 miles S. of Corunna, occupying an uneven irregular situation, encircled by hills, from which may be obtained picturesque views over the town and neighbourhood. The climate of the place is cold and damp, and the weather almost invariably rainy; but this humidity favours the vegetation of the country, so that the place is well supplied with fruit and vegetables. The town is mostly built of granite, and has a sombre appearance; the public places are embellished with numerous fountains. Many of the streets radiate in different directions from the cathedral, while those of a better class run parallel to one another. The most important building in the place is the cathedral, built about 1082, on the site of a former one. The external appearance has been injured by subsequent additions, which have been built against the outer walls, but which

Santiago
de Com-
postella.

Santiago
de Cuba
||
Santorin.

have served to protect them from the effects of the damp climate. On each of its sides is a square formed by various ecclesiastical edifices. The interior is impressive, with its long lofty naves, its dim religious light, heightening the effect of the illuminated high altar, surmounted by the image of St James. This image, no way remarkable for beauty, is an object of great reverence, and its back between the shoulders is kissed by all the pilgrims to the shrine. The most remarkable objects in the cathedral are the fine dome, two bronze pulpits in the choir, and the numerous monuments, some of them much defaced. Some of the other churches in the town are handsome; the ancient large and wealthy Benedictine convent of St Martin is now a barrack; the university, founded in 1532, and having 1030 students in 1845, has a heavy Ionic front and a handsome Doric quadrangle. The principal manufactures of Santiago are those of linen cloth and silk stockings; there is an active trade in rosaries and saints' images. The city owes its origin and importance entirely to the saint whose name it bears. He, according to the legend, after his decapitation at Jerusalem, conveyed himself into a boat and made a remarkably quick passage in seven days to Padron, a small seaport near Santiago. The body, however, lay unnoticed and unknown for nearly 800 years, until the appearance of heavenly lights over the spot pointed out its resting-place. Hence the epithet of Compostella (*Campus stella*), added to the name of the town. The bones were removed to Santiago in 829; and the first cathedral built over it in 874 became a great centre of pilgrimage, as the Spaniards were forbidden by the Pope to go as crusaders to Jerusalem as long as the Moors were in their own land. In 997, Al Mansur penetrated as far as Santiago, and destroyed the whole place except the saint's tomb; and when the new cathedral was erected, the sacred bones were for security built into the foundation. After the time of the Reformation, the pilgrimages to Santiago diminished very much in number, and the town fell into decay. It now presents a very melancholy appearance; its numerous convents suppressed and fast falling into ruins. Pop. 22,729.

SANTIAGO DE CUBA, the oldest city and formerly the capital of Cuba, on the river Santiago, about 6 miles above its mouth, on the S.E. coast of the island, N. Lat. 20.; W. Long. 76. It is well built, chiefly of stone, with straight regular streets, and a handsome public square, with an equestrian statue in bronze of Ferdinand VII. Among the more important buildings are a cathedral and other churches; and the town contains a theological seminary, several learned societies, schools, a theatre, &c. Santiago is the seat of an archbishop, and of the governor of the eastern intendency of Cuba. The harbour, though difficult of entrance, is large, deep, and well defended by several forts. In the extent of its trade it ranks next highest to Havannah and Matanzas among the ports of Cuba; the imports for 1855 amounting in value to L.500,878, and the exports to L.506,208. The climate, however, is very unhealthy, and yellow fever is very destructive here. The town is surrounded by mountains, which are not insubrious. Pop. (1850) 24,005, of whom 9610 were white people, 9396 free coloured people, and 4999 slaves.

SANTIAGO DEL ESTERO. See PLATA, LA.

SANTONA, a town of Spain, in the province and 16 miles E. of Santander, on the north side of a fine bay, on the opposite shore of which stands Laredo. It occupies a rock somewhat resembling that of Gibraltar, and, like it, joined to the mainland by a low isthmus, and it is fortified, containing barracks, arsenals, and magazines. Pop. 934.

SANTORIN, or THERA, an island in the Ægean Sea belonging to Greece, the most southerly of the Cyclades, 13 miles S. of Nio, and about 60 N. of Crète. It is of the form of a horse-shoe or crescent, about 30 miles in circumference, and nowhere more than 3 miles across. This

island was formerly united with Therasia, and formed a complete circle, having in the centre the deep crater of a submarine volcano, the rim of which may still be traced by the islands of Santorin, Therasia, and Aspronisi. The water in the inside is of great depth, though not, as was at one time supposed, unfathomable; and near the middle are three islets which have been thrown up by the volcano, two of them in ancient times, and the other, which is the largest, as late as 1707. The whole of the islands are of volcanic origin, except the southern part of Santorin, which is of limestone formation. In this portion, Mount Elias, the highest point, reaches an altitude of 1887 feet. The inner edge of the crescent formed by the island consists of rugged and steep precipices, from 500 to 1200 feet above the sea, and at the foot of these stand Epanomeria, Merovouli, and Thera, the chief towns; many of the houses nestling among the cliffs and accessible only by stairs cut in the rock. The other side of the island presents an agreeable contrast to these bare cliffs. It slopes gradually to the sea, and is entirely covered with vines, from among which numerous white villages rise. Bailey, vetches, beans, figs, &c., are also raised; but the chief product of the island is its wine, which is of good quality, and the total value of which is upwards of L.16,000 yearly. The whole annual produce of the island is about L.24,000. Santorin contains thermal and mineral springs, but there is some scarcity of fresh water, and the inhabitants, though in other respects industrious, have done little to secure the small supplies they possess. Some ancient remains have been found, and there are numerous churches and convents belonging to the Greek and Roman Catholics. The only important circumstance connected with Santorin in ancient history is its having founded the celebrated colony of Cyrene, in Africa. Pop. (1848) about 14,380.

SANTOS, a town of Brazil, in the province and 34 miles S.S.E. of San Paulo, on the north side of the island of San Vicente, in the bay of Santos, which forms an excellent harbour. It is built for the most part of stone, and contains a town-hall, arsenal, churches, convents, and hospitals. Santos is the port of San Paulo, and connected with that town by a good road. Almost all the exports of the province are shipped here, especially sugar, rice, coffee, tobacco, and cotton cloth. Pop. 8000.

SAN VICENTE, a town of Spain, Estremadura, in the province and 33 miles N. of Badajoz. It contains a parish church, several schools, a town-hall, prison, &c. The houses are for the most part well built, and the streets clean. Manufactures of hats, leather, linen, &c., are carried on, and there is some trade in cattle, hides, dried figs, and other fruit. Pop. 6888.

SAONÈ, (anc. *Arar*), a river of France, rises near Vionenil, in the department of Vosges, and flows first southwest and afterwards directly south, till it joins the Rhone at Lyons. Besides the department in which it has its source, the Saone traverses those of Haute Saone, Côte-d'Or, and Saone-et-Loire; while in the lower part of its course it separates that of Rhone on the right from Ain on the left. Its most important affluent is the Doubs from the N.E.; and among the towns on its banks are Gray, Auxonne, Chalons, and Macon. Its whole length is about 280 miles; and it is navigable as far as Gray, 190 miles above its confluence with the Rhone. By means of canals the Saone is connected with the Rhine, the Loire, and the Seine.

SAONE, *Haute*, a department of France, bounded on the N. by that of Vosges, E. by Haut-Rhin, S. by those of Doubs and Jura, W. by Côte-d'Or, and N.W. by Haute Marne. Length from N.E. to S.W. 70 miles, greatest breadth 38; area 2064 square miles. The eastern part is occupied by the Vosges Mountains and their branches; the main ridge forms for a short distance the N.E. boundary, and has two principal summits here, the Ballon de Ser-

Santos
||
Saone.

Saône-et-
Loire

vance, 3967 feet, and the Ballon de Lare, 3718 feet high. This portion of the department is rugged and barren; but not so the remainder, which occupies the centre of the wide basin of the Saône. This basin is enclosed on the north and north-west by the Faucilles, the chain of Langres, and the Côte-d'Or; on the south-east by the hills of Laumont, a branch of the Jura Mountains. All these ranges are outside the limits of the department, but some of their offshoots extend into it; its surface, however, except in the north-east, is not mountainous, but consists of gentle slopes and level plains. Through the centre of the country flows the sluggish stream of the Saône, into which flow all the rivers that water the department. The Oignon rises among the Vosges on the N.E. frontier of Haute Saône, and flows south-west, separating for the greater part of its course this department from Doubs and Jura. It joins the Saône at Pontaillier in the department of Côte-d'Or. In its geological character, Haute Saône is not uniform. The eastern portion consists of the primitive rocks of the Vosges; to the south and west of this lie beds of sandstone, and beyond these again there are strata of the various kinds that lie between the sandstone and the chalk formation. Iron, coal, granite, porphyry, and freestone are the most valuable minerals obtained in the country. Mineral and saline springs exist at various places. The climate is more moderate than in the surrounding departments, being neither so hot in summer nor so cold in winter. The autumns are very fine, but sudden changes of weather are not uncommon in spring. The soil in the loftier regions is not very good, and the mountains are almost all covered with forests; but the more level districts are of great fertility. Fine meadows occupy the plains; and the sloping hills are covered with vines and corn-fields. Although agriculture is not very far advanced, the produce of the country in corn and wine is more than sufficient for the consumption. About half of the area consists of arable land, and about a fourth is occupied by wood—oak, beech, and fir being abundant. About 150,000 acres are occupied by meadows and pasture-land, and 55,000 by moors and heaths. The vineyards, which cover an area of 30,000 acres, produce wine of a very ordinary quality. Wolves, foxes, squirrels, and otters, are among the wild animals of the country. Game is plentiful, and the rivers abound in fish. The rearing of cattle is much attended to, as well as of horses and pigs, and the breeds of all these animals are good; but sheep are neglected. It is calculated that the department contains 150,000 horned cattle, 32,000 horses, 110,000 sheep, 80,000 pigs, and 12,000 goats. The manufactures comprise iron, for which there are from 35 to 40 furnaces, 60 foundries, and 2 steel manufacturing, ironmongery of all kinds, glass, pottery, leather, cotton thread and cloth, paper, oil, brandy, &c. Some trade is carried on in wine, corn, and other rural produce, horses, cattle, timber, and iron. Large quantities of the produce are floated on rafts of timber down the Saône, which forms one of the principal means of internal communication. There are numerous roads throughout the department; and a railway is in course of construction, which will traverse the country. Haute Saône belongs to the diocese of Besançon, and, besides Roman Catholic churches, contains 4 Protestant ones, and 3 synagogues. It has law-courts, subject to the Court of Appeal at Besançon, a normal school, 4 colleges, 7 upper, and 1100 elementary schools. There are three arrondissements, subdivided as follows:—

	Cantons.	Communes.	Pop. (1856).
Vesoul	10	215	102,228
Gray	8	165	81,301
Lure	10	203	128,868
Total	28	583	312,397

The capital of the department is Vesoul.

SAONE-ET-LOIRE, a department of France, bounded

Saône-et-
Loire.

on the N. by that of Côte-d'Or, E. by Doubs, S. by those of Ain, Rhone, and Loire, W. by Allier, and N.W. by Nièvre. Length from E. to W. 85 miles, greatest breadth 68; area 3305 square miles. It is traversed from north to south, in the centre, by the Charolais and Mâconnais Hills, which form a northern prolongation of the Cevennes, connecting that range with the Côte-d'Or, the Faucilles, and ultimately with the Vosges. The southern portion of these hills consists of several parallel ridges, with valleys between them, down which rivers flow either to the Saône on the one side, or to the Loire on the other. Towards the north, the breadth of ground occupied by the hills diminishes; and the number of separate ranges is reduced to two, with a valley between, opening at either end to the level ground on different sides, so as to permit a communication; and this has afforded a passage for the canal that connects the Saône and the Loire. The highest summit of these hills is Mount Blauvray, 3280 feet above the sea. The ground on either side slopes gradually down to a level surface—that on the east side belonging to the basin of the Saône, and that on the west to the Loire. These rivers flow in opposite directions, the former towards the south, and the latter towards the north; and they, with their affluents, are the principal streams that water the department. Both are navigable through their whole course in Saône-et-Loire, and the Saône receives the Doubs and the Seille, the Loire, the Arconce, Arroux, and others, within its limits. The department has also some small lakes. Granite is the prevailing rock in the hills and western plain, while the geological structure of the Saône basin is oolitic. Along the banks of both the great rivers, however, there are tertiary deposits. The climate is in general temperate; among the hills it is cold and variable; but much more genial weather prevails in the lower ground. The soil is in general extremely fertile, and the surface is varied with rich corn-fields, green meadows, and vineyards, covering the hills and dales of the country. Corn is chiefly grown to the east of the Saône; the central portion between that and the hills is the vine-growing part of the country; and the western slope is chiefly occupied with pasture-land. Of the whole area, about 1,632,000 acres are occupied by cultivated land, 417,000 acres by wood, and 87,000 by heaths and waste lands. The corn produced is, on the whole, more than sufficient to supply the demand; for although some parts of the department import it, this is made up for by the exportation from other districts. The wines produced here are in considerable repute, though not esteemed of first-rate quality. A great number of cattle, and especially of sheep and pigs, are raised here; and the oxen of the Charolais have a reputation little inferior to the best Swiss breeds. It is calculated that there are in the department more than 240,000 horned cattle, 150,000 pigs, and 370,000 sheep. Wolves and wild boars are found in the mountains. The minerals of the country contribute in no small degree to its wealth. The coal-fields in the valley of the Arroux are among the richest in France; iron is also obtained in great abundance; and at Romanèche there is a rich mine of manganese, which yields annually about 80,000 tons of that mineral. There are, too, in the department quarries of marble, alabaster, and freestone. Besides the mining operations, various branches of industry are carried on. The most important of these is the manufacture of iron, and next to that those of glass, pottery, leather, cotton cloth, paper, hats, &c. The principal articles of trade are iron, coal, leather, corn, and wine. The internal means of communication are numerous, as there are two navigable rivers, joined by the Canal du Centre, numerous roads, and a railway which traverses the valley of the Saône. The department forms the diocese of Autun, and has several courts of law under that at Dijon. It contains also a lyceum, normal school, 5 colleges, 7 upper, and

Sao Sebastiao 670 elementary schools. The capital is Mâcon, and there are 5 arrondissements, as follows:—

	Cantons.	Communes.	Pop. (1856)
Mâcon	9	131	120,297
Autun	8	85	104,595
Châlon-sur-Saône	10	152	134,480
Charolles	13	136	129,911
Louhans	8	81	85,735
Total	48	585	575,018

SAO SEBASTIAO, a seaport of Brazil, on the Atlantic coast, opposite an island of the same name, in the province of San Paulo, and 65 miles E.N.E. of Santos. It is wretchedly built, with mean houses and unpaved streets, but contains a church, convent, and schools. The harbour is large, and the trade of the place considerable. Pop. of the district 6000.

SAPPERS AND MINERS, ROYAL. See ARMY.

SAPPHIRE. See MINERALOGY.

SAPPHO (Σαπφώ, Æolic Ψάπφα), a very celebrated Grecian poetess, was a native of the island of Lesbos, and was nearly contemporary with her countryman Alcæus, with whom she divided the leadership of the Æolic school of lyric poetry. She must have been younger than that poet, as she was still alive in 568 B.C. It cannot now be ascertained whether she was a native of Eresos or of Mitylene; but the supposition of K. O. Muller (*Hist. of Greek Lit.*, vol. i. p. 172), may perhaps bear some degree of plausibility, that at the time of her greatest celebrity she passed from the lesser city to the greater. Few circumstances relating to this illustrious woman can now be ascertained. About 596 B.C., while still in the bloom of youth, she sailed from her native island to take refuge in Sicily; and at a much later period she produced the ode alluded to by Herodotus (ii. 135), in which she reproached her brother Charaxus for purchasing Rhodopis or Doricha of Naucratis in Egypt,—a beautiful courtesan, with whom he had fallen desperately in love. The severity with which the censure is laid on has induced the majority of the later critics to treat as a libel the current charge of Sappho having herself occasionally sacrificed to the goddess of love. It was formerly a pretty common belief that Sappho took a violent leap into the sea from the Leucadian rock, because her love was not requited by a youth named Phaon, to whom it had been addressed. It is true a youth is frequently mentioned, but never by name, in her odes; and it is just possible she may have alluded in some of her verses to Adonis, the favourite of Aphrodite, who in some legends is called Phaon and Phaëthon. But the whole story is likely to have originated in some highly poetical expression used by the author. Besides, as Welcker and others have remarked, it is not told by any of the preservers of the legend whether Sappho survived the leap or perished by it. Sappho, like all the early lyric poets, sang the praises of Love and Marriage. She sang them with simplicity and directness, and with a warmth of poetic fire which emanated from uncommon poetic endowments. In the remains of her lyrics which survive, there is no line calculated to cloud her fame, as there is none to cloud her genius. They contain passages in which the poetess repels with dignity the least transgression of the bounds of social intercourse as understood by the Æolians; but it is precisely because the manners of that race are so little understood, that men have chosen freely to calumniate the name of this great poetess. Müller justly remarks, that at the time at which Sappho wrote, the line had not been drawn with any degree of exactness between sensual and sentimental love. The Attic comic poets could neither understand the simplicity of that simple time, nor could they indeed comprehend it at all. They accordingly made short work of it, by introducing Sappho into their licentious dramas as a common courtesan.

Those who wish to see the character of the poetess vindicated from the numerous charges which have been brought against it, may read the little work of Welcker, *Sappho von einem herrschenden Vorurtheil befreit*, Göttingen, 1816; and the writings of K. O. Muller, Neue, Ulrici, Bode, &c. To form a true estimate of the erotic poetry of Sappho, one must have recourse to the few fragments of it which now remain. Of the nine books of erotic odes, epithalamia, hymns to the gods, and other poems which Sappho originally left, only one complete ode and a number of short fragments are now left. Judging from the very scanty material at our disposal, it is not difficult to justify the admiration of the ancients. In purity and fervour, in delicacy and sweetness, in grace of diction and in harmony of construction, Sappho may be fairly pronounced equal to the greatest lyric poet of any age or country. The *editio princeps* of the hymn to Aphrodite was published by H. Stephens in his edition of Anacreon, with whom Sappho's poems have been usually printed, in 1554. Since then there have been countless editions of her fragments, from the simple text up to the most cumbersome elaboration of annotation. In the latter respect Volger, Leipzig, 1810, decidedly bears away the palm; while the edition of Neue is regarded as the first in point of excellence. It bears the name of *Sapphonis Mytilenææ Fragmenta, Specimen Operæ in omnibus Artis Græcorum Lyricæ Reliquiis, excepto Pindaro collocandæ, proposuit*, C. F. Neue, Berlin, 1827. Sappho has been frequently translated into all the European languages. What is called the Sapphic measure is the most important of all the Sapphic metres. It corresponds very closely to the measure employed by Alcæus. That used by Sappho, and which bears her name, has a short syllable at the end of the verse, while in the Alcaic measure the syllable begins the line. According to the improved scansion of Professor Key (*Journal of Education*, vol. iv.), the Sapphic measure is as follows:—

— — — — —
Grandinis misit pater et rubente.

The Sapphic and Alcaic are most probably the favourite measures of Æolian lyric poetry. The near resemblance of the two verses, as well as their frequent employment by the poets of Lesbos, and in the odes of Horace and Catullus, afford good evidence of this proposition.

SARABAND, in Spanish *zarabanda*, a Spanish dance in $\frac{3}{4}$ time, formerly danced with castanets. The movement is rather slow. In the music of Corelli and other old masters, sarabands are of frequent occurrence.

SARAGOSSA (Sp. *Zaragoza*), a province of Spain, bounded on the N.E. and E. by that of Huesca, S. by that of Teruel, S.W. by that of Guadalajara, W. by that of Soria, and N.W. by that of Navarre; area 11,783 square miles. It is not so mountainous as the other portions of Aragon, of which ancient kingdom it once formed a part, lying principally in the valley of the Ebro, which traverses the province from N.W. to S.E. This valley, from 70 to 80 miles broad, is enclosed on the S.W. by the Sierra de Moncayo, the highest hills in the province, and on the N.W. by the Sierra de Sobrarbe. The latter separates from the valley of the Ebro that of its affluent the Aragon. Several other rivers water the country, all flowing into the Ebro; the Jalon, Huerba, and Aguas from the right; the Arva and Galleogo from the left, being the largest of these. The soil is in the level portions pretty fertile, and agriculture is the principal occupation of the people. Wheat, rye, barley, oats, hemp, flax, oil, and wine are the chief productions; silk-worms are also bred; and there are extensive forests which yield wood for charcoal. There are no important manufactures, silk and soap being the only articles which were formerly made to a considerable extent, and even these branches of industry have now much fallen off. Pop. (1851) 297,336.

SARAGOSSA, the capital of the above province, and for-

Saraband
||
Saragossa.

Saragossa. merly of the kingdom of Aragon, in a rich plain on the Ebro, just above its confluence with the small river Huerba, 180 miles N.E. of Madrid. It is built on the south side of the river, which is crossed by a fine stone bridge erected in 1437. Encircled by walls, and substantially built, with numerous domes, towers, and spires, it looks very imposing from a distance, but has a dull and gloomy appearance on a nearer approach. The streets are narrow, crooked, and ill-paved, the grand old mansions deserted or in ruins, and the whole town crowded with beggars and lumbering rustic waggons. Along the river's side there are fine public walks and avenues of poplar-trees. The chief buildings of the town are the two cathedrals, in each of which the chapter resides alternately for six months. They present in almost all respects a complete contrast,—the one ancient and stately, in the Gothic style; the other like an oriental building, with multitudinous domes and variegated tiles. The interior of the former is very fine, and has many interesting monuments. The latter is quadrangular, with three naves, and is entirely dedicated to the worship of the Virgin, the chief object of adoration being a pillar of alabaster, on which she is said to have alighted. This relic is enclosed in a small chapel inside the cathedral, and a hollow has been worn in it by the lips of the worshippers. The new tower, or tower of San Felipe, like the celebrated one of Pisa, diverges about 9 feet from the perpendicular, a defect caused by the sinking of the foundation. It is built of brick, richly ornamented, and is lofty enough to command a fine view of the city and environs. Among the eighteen churches of the town, that of San Pablo is remarkable for its grand architecture; and that of Santiago is said to cover the site of the lodging place of the apostle to whom it is dedicated. Saragossa contains one of the largest hospitals in Spain, and a *Casa de Misericordia*, or poor-house, with accommodation for 600 or 700 inmates. The university, which was founded in 1474, had, in 1841, 1100 students. It formerly possessed a fine building and valuable library, but these were destroyed by the French, and a new edifice, with a handsome quadrangle, has been partially erected. Another remarkable building of the town is the *Aljaferia*, or old citadel, an irregular pile, standing outside the N.W. gate. It was originally built as a palace by the Moors; subsequently occupied by the Inquisition; afterwards used in succession as a barrack, military hospital, and prison. It is now unoccupied and falling into decay, although it contains a splendid staircase and many magnificent halls. Besides the establishments already mentioned, Saragossa contains various schools and convents, a museum, public library, botanic garden, theatre, baths, &c. Leather, silk, and woollen cloth are manufactured, and there is some trade in agricultural produce carried on by the Ebro. The most ancient name of the town was Salduba, or Saldyva, which was given to it by the Celtiberians, who originally inhabited this country. After the Cantabrian war it was colonized by Augustus, B.C. 25, who gave to the place his own name, calling it *Cæsar Augusta*, or *Cæsarea Augusta*. It early renounced the pagan religion, and is said to have been the birth-place of Prudentius, the earliest Christian poet. No remains of the ancient city have been preserved. About 470 A.D. it was taken by the Goths, and in 712 by the Moors, who corrupted the Roman name into that which it now bears. In 1118 Alonzo, surnamed *el Batallador*, wrested Saragossa from the Moors after a siege of five years, during which the defenders were reduced by famine to the utmost straits. In 1710 the British general, Stanhope, defeated the French under Philip V., not far from the town. But the most memorable events in connection with Saragossa are those which took place during the French invasion of Spain. In 1808 the citizens rose against the invaders, and, under the command of Palafox, defended the town for two months, favoured by the strength of the place

and their own obstinate courage. The first siege was raised August 15th, 1808; but the respite thus gained was not made use of to strengthen the defences; and when the French attacked the place again in greater force, it was compelled to surrender, February 20th, 1809, having lost in all nearly 60,000 men. Pop. 82,189.

SARAIISK, a town of European Russia, capital of a circle in the government and 35 miles W.N.W. of Riazan, on the Osetr. It has eight churches, five of stone and three of wood; two schools, two charitable institutions, an old stone citadel, and numerous gardens. Carpentry is carried on here, as well as the manufacture of tar and rosin; and there is an active trade in cattle. Pop. 6332.

SARANSK, a town of European Russia, capital of a circle in the government and 70 miles N. of Pensa, at the confluence of the Insara and Saranka, in a very fertile country. It is an irregular place, with crooked, ill-paved lanes; and contains numerous churches, a school, and an hospital. Here are salt magazines, and manufactures of soap, sail-cloth, &c. Some trade is carried on. Pop. 5443.

SARAPUL, a town of European Russia, capital of a circle of the same name in the government of Viatka, on the Kama, 195 miles S.E. of Viatka. It is commanded by a fort on an adjacent hill; and contains a cathedral and other churches, besides various schools and hospitals. There are here manufactures of soap, jewellery, and cloth; some river navigation, and an active trade in corn and salt. Pop. 7668.

SARATOGA SPRINGS, the most fashionable watering place in America, in the state of New York, 38 miles N. of Albany. It is only celebrated for its mineral waters, as the scenery in the neighbourhood has not many attractions; but it is resorted to by multitudes of all classes for the sake of health or pleasure. There are numerous large and splendid hotels here; as well as churches, academies, &c. The number who visited the place in the summer of 1853 is estimated at 30,000. Near this, in 1777, the British troops under Burgoyne surrendered to General Gates. Pop. 4650.

SARATOV, a government of European Russia, lying between N. Lat. 48. and 53., E. Long. 42. 20. and 48.; bounded on the W. by the government of Voronetz and Tambov, N. by those of Pensa and Simbirsk, E. by that of Samara, S. by that of Astrakhan, and S.W. by the land of the Don Cossacks. Area 54,797 square miles. A chain of hills, pretty high in the southern portion, stretches from S. to N. through the western part of the country, and divides the waters of the Don from those of the Volga. From these heights eastward to the Volga, which flows southwards, and forms the eastern boundary of the government, the country is hilly and undulating. That river receives no important tributaries in the government, and a large portion of the country in the S. and W. is watered by affluents of the Don; the principal of which are the Choper and Medveditza. The hills are composed of slate and limestone rocks; and the soil of the lower ground is for the most part fertile, especially in the N.W. portion, where no manure is needed to render the ground productive. Further south the soil is somewhat stony and barren. In the forests, which lie chiefly in the N.W. of the government, oaks, pines, poplars, and maple, are the principal growth. Agriculture is the chief occupation of the inhabitants. Saratov contained in 1849, 7,202,282 acres of arable land; 15,892,868 acres of meadows; 3,249,129 acres of wood; and 21,437,864 acres of waste land. The produce of corn in the same year was 55,276,886 bushels, and that of potatoes 896,290 bushels. These numbers, however, include part of what now forms the new government of Samara, which had not been constituted at that date. The number of horses within the old limits in 1849 was 861,008; of horned cattle, 839,526; of sheep, 1,756,450;

Saratov
||
Sardinia.

of swine, 257,216; and of goats, 22,896. The principal crops raised are rye, wheat, oats, millet, hemp, and flax; tobacco and hops have been introduced; and in some places mulberries and even vines are cultivated. The fisheries on the Volga are productive. Iron, salt, and millstones, are the only important mineral productions. The manufactures are chiefly carried on by the foreign settlers, who were introduced into the country in great numbers from Germany and Switzerland by Catherine II. The number of establishments in 1849 was 140, employing 1449 hands. The most important factories were 37 tanneries, 25 tallow-houses, and 14 tile-works. The country is well situated for trade, communicating by means of the Volga with the west of Russia and the Caspian; and by the affluents of the Don with the Black Sea. Besides the foreign settlers, the population consists of Russians, Tartars, and Cossacks. The majority belong to the Greek Church; but there are 81,753 Protestants, 18,672 Roman Catholics, 42,571 Mohammedans, and 529 Pagans. Education is generally in a low condition in the country. For administrative purposes, Saratov is divided into ten circles, as follows:—

	Pop. (1851.)		Pop. (1851.)
Saratov	204,339	Kamyschin	152,166
Zaritzin	53,688	Atharsk	180,149
Volsk	122,047	Balaschov	185,253
Kusnetzsk	117,255	Chvalynsk	125,005
Petrovsk	157,287	Serdobsk	141,893
			1,439,182
Astrakhan Cossacks			5,314
		Total	1,444,496

SARATOV, the capital of the above government, on the right bank of the Volga, 386 miles N. of Astakhan, and as far W. of Orenburg. It stands in a valley between the river and a wooded limestone hill, and is neither handsomely nor regularly built, for the most part only of wood. It contains several Greek churches, some of them built of stone; as well as others belonging to the Protestants and Roman Catholics, a mosque, and two monasteries. Saratov is the seat of a Greek archbishop, and of a Protestant consistory; it has also government offices, a college, and various schools, hospitals, &c. There are large salt magazines, a botanic garden, and a bazaar or market-place, where a large annual fair is held. The principal articles manufactured here are leather, sail-cloth, cotton stuffs, cordage and hats. An active trade is carried on by the Volga. Pop. 61,610.

SARAWAK. See BORNEO.

SARAWAN, a province of Beloochistan, lying between N. Lat. 27. 53. and 30. 20., E. Long. 64. and 67. 40.; bounded on the W. and N. by Afghanistan, E. by Afghanistan and the province of Cutch-Gundava, and S. by those of Jhalawan, Kelat, and Mekran. Length from N.E. to S.W. about 250 miles, greatest breadth 80; area about

15,000 square miles. It is a very mountainous and rugged country, and is enclosed by mountain ranges on the E., N., and W. Those on the E. are traversed by the Bolan Pass, leading into Cutch-Gundava; and those on the northern frontier contain the lofty summit of Tukatoo, estimated at 11,000 or 12,000 feet high. There are some very fertile valleys and plains in Sarawan, especially the valley of Shawl in the N., and that of Musturg, separated from it by a barren plain, 20 miles broad; but in general the country is very dry, having no large stream except the Bolan, which flows through the pass of that name. The population is estimated at 50,000; and the chief town is Sarawan, a collection of mud houses, with a wall of the same material, and 4000 inhabitants.

SARCOPHAGUS (σάρξ *flesh*, and φαγέω *to eat*), a sort of stone coffin or grave, in which the ancients deposited the bodies of the dead which were not intended to be burned. It is supposed to be derived from the *Lapis Assus*, a stone much used among the Greeks in their sepultures, recorded to have always perfectly consumed in forty days the flesh of human bodies buried in it. There was also another fabulous quality assigned to it—namely, its power of turning into stone anything put into vessels made of it. One of the most celebrated specimens of antiquity is the great sarcophagus, which is commonly called the tomb of Alexander the Great. It fell into the hands of the British at the capitulation of Alexandria in Egypt in 1801, and is now deposited in the British Museum.

SARDANAPALUS, the last King of the Assyrians, according to the Greek and Roman writers, was the thirtieth from Ninus, of whom Herodotus merely mentions that he concealed his treasure in subterranean vaults. The character usually ascribed to him is that of a luxurious and slothful prince, who spent the greater part of his time in the harem among his women. But it is difficult to reconcile this statement with the brave and obstinate resistance he made to the attack of the rebel Arbaces, prince of Media. He defeated Arbaces twice, but at last was shut up within Ninus (Nineveh), where he destroyed himself with all his women and his treasures on a funeral pile. There would seem, however, to have been another Sardanapalus, the son of Anacyndaraxes, who is said to have founded Tarsus and Anchiale in one day, and whose epitaph is frequently quoted; and it is not unlikely that Ctesias, from whom Diodorus quotes, has mixed up the events that happened to these two. The second is thought to be the Esarhaddon of the Scriptures, and the first to be the Saracenus of Abydenus. But regarding the whole matter there seems to be very much doubt. The late excavations at Nimrud have brought to light several particulars not very reconcilable as to the existence and reign of Sardanapalus. His annals are proposed to be published by Sir H. Rawlinson and E. Norris.

Sarcophagus.
||
Sardinia.

SARDINIA.

THE dominions of the House of Savoy, called in Italian the *Regno Sardo*, have an area of 29,075 English square miles, with a population (in December 1857) of 5,172,283 inhabitants. They are composed of two separate parts—the continental territories, which in Italian are styled *Stati di Terra Ferma*, and the islands of Capraia and Sardinia, the latter of which gives the title of King to the head of the state.

The continental possessions, consisting of what formerly were the principality of Piedmont, the duchies of Savoy, Genoa, and Montferrat, the counties of Nice and Asti, the marquisesates of Susa, Ivrea, Salluzzo, and Ceva, &c., have

an area of 19,774 square miles, with a population of 4,590,206 inhabitants, and extend in N. Lat. from 43. 30. to 46. 27., and in E. Long. from 5. 35. to 10. 9. With the exception of the southern portion of the Lunigiana, lying east of the Magra, they comprise the country extending between that river and the Var, the Ticino and the Rhone; and are bounded on the N. by Switzerland, on the W. by France, on the S. by the Mediterranean Sea, and on the E. by the grand duchy of Tuscany, the duchy of Parma, and the Lombardo-Venetian kingdom.

The island of Sardinia, with the adjoining small islands of St Antioco, San Pietro, Asinara, Maddalena, and several

Sardinia. smaller ones, has an area of 9301 square miles, with a population of (in December 1857) 577,282. It lies north-west of Sicily, north of Africa, and south of Corsica, from which it is separated by a narrow strait called *Bocche di Bonifacio*, and extends in N. Lat. from 38. 52. to 41. 16., and in E. Long. from 8. 10. to 9. 50. Sardinia is the largest and, next to Sicily, the most important island in the Mediterranean Sea. Capraia, which has only 15 miles in circumference, and 4741 inhabitants, is situated east of the northern extremity of Corsica, north-west of Elba, and west of the Tuscan coast.

The surface of the *Stati di Terra Ferma* presents the greatest possible variety. On the north and west it is covered by the Alps, and on the south by the Apennines; and between these two great mountain chains lies the most fertile and valuable portion of the kingdom, consisting of the slopes, valleys, and plains that form the upper basin of the Po, from its source to its junction with the Ticino below Pavia.

The two divisions of Chambery and Annecy, to the north-west, including what formerly was the duchy of Savoy, are in physical aspect, as well as in the general character and language of their inhabitants, more a part of Switzerland than of Italy. They are an alpine land separated from the plains of the peninsula by an enormous chain of mountains known as the Graian Alps. Its lofty mountains covered with eternal snow and glaciers, its long and deep valleys, its numerous cascades, the raging winds and violent storms of rain, hail, and snow, which occur with frequency in the elevated regions, give Savoy a peculiar and lasting interest. In ancient times it formed part of the country of the *Allobroges*.

The three divisions of Nice, Savona, and Genoa, formerly the county of Nice and the territories of the Genoese republic, and known by the general name of the *Riviera*, surround the Gulf of Genoa, and include all the sea-shore of the continental possessions from the Var to the Magra. They are the ancient *Liguria*, which, according to the division of Augustus, constituted the 9th region of Italy, and are poetically pointed out by Dante as the rugged country, "*Tra Lerici e Turbia*." It is a narrow strip of land, bordered along its whole extent by the ranges of the Maritime Alps and the Apennines, and cut everywhere by narrow valleys and deep ravines. In some places the mountains rise so abruptly from the sea-shore as to render any passage impossible except by means of galleries cut through their projecting spurs. The chief ports, in the order of their importance, are Spezia, the ancient *Portus Lunæ*, placed at the eastern extremity, one of the most spacious and safe harbours in the Mediterranean Sea, and which of late has been made the principal station of the Sardinian fleet; Genoa; Villafranca; Savona; Nice; Porto-Maurizio; and Mentone. The tract from Savona to Sestri di Levante is more thickly inhabited than any other part of the kingdom, with the exception of the neighbourhood of Turin.

The remaining six divisions of Turin, Ivrea, Cuneo, Vercelli, Novara, and Alessandria, comprise the fertile region extending downwards from the Alps and the Apennines, and forming part of a vast valley, or rather plain, which begins at the foot of the Monviso, and only terminates on the easternmost frontier of Italy, at the Adriatic Sea. The River Po divides this valley into two nearly equal portions. Its northern side, which in ancient times formed part of *Gallia Transpadana*, or the 11th region of Augustus' division, extends to the foot of the Alps, some great projections of which enter it in the provinces of Ossola and Aosta. The southern side, which was part of ancient *Gallia Cispadana*, or the 8th region, is bordered in its whole length by the ranges of the Maritime Alps and the Apennines. Piedmont, the name given in a large sense

to the whole of this country, is divided from Switzerland and Savoy by the Helvetic and the Graian Alps, from France by the Cottian Alps, and from the Riviera by the Maritime Alps and the Apennines.

The mountains of the continental states have already been fully described in this work under the general articles ALPS and APENNINES. The principal rivers are the Po, the largest river of Italy, which has its source in two springs on the eastern slope of Monteviso, at a height of 6562 feet above the level of the sea; the Ticino, which forms the boundary between Lombardy and Piedmont; the Sesia, the Dora Baltea, and the Dora, all tributaries of the Po on its northern side; the Tanaro and the Bormida, which join at Alexandria, and flow into the Po on its southern side; the Var, which constitutes the boundary between the province of Nice and France; and the Magra, which flows into the Mediterranean, outside the Gulf of Spezia.

The larger lakes of the Alps belong only in part to this kingdom. The Lemman, or Lake of Geneva, is divided between Sardinia and Switzerland, the southern bank of it only belonging to the kingdom. The Lago Maggiore or of Locarno (*Verbanus*)—for a description of which see LOMBARDY—has also only its western shores within the Sardinian dominions, the eastern side belonging to the Lombardo-Venetian kingdom, and the upper part forming a portion of Switzerland. The lakes exclusively Sardinian are of much smaller extent. The Lake of Orta is a long narrow sheet of water by the side of Lake Maggiore, into which its surplus water is discharged. The Lake of Annecy, in Savoy, is 1350 feet above the level of the sea, and 180 feet in depth. It has an outlet by the rivers Thor and Fior into the Rhone. The Lake of Bourget, near Aix-le-Bains, scarcely exceeds 100,000 acres in extent, but is about 240 feet in depth, and by means of the canal of Savières, discharges much water into the same river. There are some smaller lakes, a few of which are dried up in the summer; others of them are on elevations of great height, the most remarkable of which is one on Mont Cenis, 5740 feet above the level of the sea.

The several states abound in mineral springs; those that have attained greater celebrity are the hot springs of Acqui in Montferrat, which are impregnated with sulphuretted hydrogen; the medicinal springs of St Vincenzio, in the valley of Aosta; and in Savoy the warm baths of Aix, and the sulphureous wells of Bonneval.

A more detailed geographical description of each of the great divisions of the continental territories is given in this work under GENOA, PIEDMONT, and SAVOY.

The climate of the *Stati di Terra Ferma* varies excessively in the different provinces. In Savoy, in the valleys of Aosta and Ossola, and among the Alps of Piedmont, a real Swiss climate prevails. The air in these districts, though changeable, is on the whole pure and healthful, but is too raw to bring forth the fruits of Italy; in favoured spots, however, the grapes ripen, and the sides of the hills are covered with chestnut-trees. In the upper valley of Piedmont the thermometer falls below 10 degrees in winter, and in the neighbourhood of the mountains it is not unusual to see the ground covered with snow during twelve days or a fortnight. Night frosts, which begin in November, continue till April; and even in the midst of summer, cold winds occasionally descend from the heights. The mulberry-trees, the vines, and the maize flourish; and the air, when not in the vicinity of rice-fields, is remarkably pure, and has a balmy fragrance. Along the whole coast from Nice to the Magra, which is protected by the mountains from the cold winds, the climate is much milder and more agreeable. In some favourite spots which are entirely sheltered from the north and north-east winds, the thermometer rarely, if ever, falls below the freezing-point; and the vegetation, combining the botany of Southern Europe and Northern Africa with those of the tropics, is of

Sardinia. singular beauty. The mountains are clothed with sweet chestnuts, their slopes with olive-trees, and figs and orange-trees grow luxuriantly along the sea-shore.

The chief occupation of the inhabitants of this kingdom consists in the cultivation of the land, and is accordingly as varied as the surface of the soil and as the climate, which depends on the elevation. Under the head of **LOMBARDY** will be found a detailed account of the agriculture of that district, the greater part of which may be adverted to as a description of what takes place in the richer portion of Sardinia, which belongs to the basin of the River Po, comprehending the greater part of the provinces of Turin, Cuneo, and Alessandria. Here we shall only add that the most important article of cultivation is the mulberry-tree, the produce from which, and the price it fetched in the market for the last six years, was,—

	Cocoons		Price.
1853	1,025,287	lb.	L.373,987
1854	1,410,454	"	529,523
1855	1,830,353	"	706,398
1856	4,535,346	"	853,306
1857	1,001,811	"	824,900
1858	724,332	"	30,256

In Savoy generally the cultivation is badly conducted. The cultivable land is divided into large portions, belonging to a few great proprietors, and is subdivided into smaller portions to tenants, who, without leases, transmit their lots from one generation to another, paying neither money-rent nor labour to their superiors, but delivering to them or their agents one-half of the produce of the fields, whatever it may be, in its several kinds. The cattle on these lands are commonly the property of the lord, and are maintained on the produce of the soil, before the division is made of what it yields. The power of the tenants to transmit the land to their successors is combined with the power of subdividing it among their several children; and this is carried to such an extent that it has led, and is leading, to such a subdivision that a great number of the farms barely raise sufficient food for the occupants, though their provisions are of the most humble and penurious kind. Savoy is annually deficient in corn to the extent of nearly one-third of its consumption. This is in some measure made up by using chestnuts and potatoes as substitutes for bread. In Aosta and in some other parts the potato is little cultivated, and corn is supplied to them from the neighbouring districts. Along the Riviera the land consists chiefly of narrow strips of valley, which in the greater portion is composed of sand, and is not very appropriate for the growth of grain, though a little is grown in some of the more fertile valleys. The common people derive part of their subsistence from chestnuts, other fresh and dried fruit, fish (especially Sardines, which at some seasons are very abundant), and from an inferior kind of cheese made by themselves; and oil, a useful accompaniment, is at a very moderate price.

The *Regno Sardo* cannot be considered as a manufacturing country, except for the purposes of domestic consumption. Before the seventeenth century, Genoa was the centre or channel of all the supply of manufactured silks and velvets to the other parts of Europe; but at present the manufacturing industry, as regards silk, is reduced almost to the point which the internal consumption demands, or to the process of preparing the raw material for the manufacturers of France, England, Holland, Germany, and Russia. Their silks are handsome and strong, especially the stockings; but, in the absence of the best descriptions of machinery, they are dearer than elsewhere. Silk stuffs, velvets, paper, musical instruments, and some kinds of jewellery, principally manufactured at Genoa, are almost the only articles of export.

The physical aspect of the island of Sardinia is greatly diversified, and more than eight-tenths of its surface are covered with mountains, of which the main chain extends

along the whole eastern side, from the headland called Cape Lurgo Sardo, opposite Corsica, to Cape Carbonara in the south; none, however, of these mountains reach such an elevation as to be covered with perpetual snow. The loftiest range is that of Genargentu in the Barbagia district, in the middle of the island. Its highest summit, the Punta Bruncu Spina, is 6293 feet above the level of the sea. Next in importance is the granitic chain of Mount Limbara, which covers the district of Gallura in the north; its highest peaks attain an elevation of more than 4000 feet. The mountains in the centre and the south of the island, including the Genargentu, chiefly belong to the palæozoic formations, through which arose at different ages the numerous extinct volcanoes that render the island so interesting to the geologist. The most important volcanic tract is north of the River Tirsì, between the Gulf of Oristano and Sassari, where the highest lip of the crater of Monte Urticu, near Milis, reaches 3440 feet above the sea-level. Between the Gulfs of Cagliari and Oristano is the extensive plain of the Campidano, scattered with many populous and flourishing villages. Next in extent to the Campidano is the Campo d'Ozieri in the north of the island, south of the Limbara Mountains. The principal rivers are,—the Flumendosa, which springs from the Genargentu Mountains, waters the Barbagia district, and falls into the sea near Muravera on the eastern coast; the Coginas, which has its sources in the Limbara group, and falls into the Gulf of Torres on the north; the Mannu, which waters the Campidano, and joins the sea in the Gulf of Cagliari; the Tirsì, which has the longest course of all, and after traversing most of the island from N.E. to S.W., flows into the Gulf of Oristano; and the Flumenbosa, which rises among the volcanic range on the W., and empties itself into the sea below Bosa.

Mineral springs are numerous, but are for the most part neglected. The principal are those of Sardara, Villa Cidra, and Fordongianus, those at the foot of Castel Doria, at Codrongianus, and the Benetutti springs of the Goceana Mountains. They are all on the W. side of the island. In a secondary rank may be noticed the thermal waters of Marrubiu, of Iglesias, and of St Antonio. Aqua Cotta, at the eastern base of an insulated hillock near Villa Cidra, is a small but constantly limpid spring, of about 105° of Fahr., close by a stream of potable water having a temperature of 60°, whilst that of the atmosphere is 64°. Here most of the cloth of the Campidano is filled, the makers of it paying to the proprietor for the use of the water.

The situation and the soil of the island are favourable to the cultivation of all those trees and plants which grow in Spain, in Italy, and in Sicily. Its mountains are clothed almost to their summits with forests of cork, green oak, common oak, pine, sweet chestnut, and other trees. The wild olive covers extensive tracts in the hilly districts. Figs, vines, and pomegranates thrive wonderfully, with scarcely any cultivation. The madder and liquorice roots grow wild in some districts. The orange forest of Milis, on the western coast, shows no appearance of cultivation, and has trees compared with which the finest orange-trees in Portugal would seem dwarfs. Lemons, apple, pear, walnut, carrouba, almond, peach, and mulberry trees; flax, hemp, saffron, and every variety of grain, are among its productions. Corn, even under the present system of agriculture, gives a return of 7 or 8 for one, and in some districts the average is said to amount from 16 to 20 fold. There are no wolves. The "mouflon," a ruminating animal, frequenting only the highest and most secluded woods, is a native of the island. Deer, wild boar, and a variety of game abound in the forests; so that there are annually exported about 60,000 skins of hares and rabbits, 5000 of foxes, and 2000 of martins.

With all these natural advantages, this island, which

Sardinia.

Sardinia. In ancient times was reckoned with Sicily a granary of Rome, was sadly neglected, and remained till very recently in a semi-barbarous state. The Vandalic invasion; the anarchy into which it fell during the middle ages; the establishment of the feudal system in a most vexatious and oppressive form; its having long been a dependency of Spain, and for centuries misruled worse than Spain itself; its partition into vast estates, many of which belonged to distant Spanish grandees;¹ and the numerous restrictions upon industry and commerce, were some of the most prominent causes that paralysed the industry of its inhabitants, diminished their number, and changed its fertile plains and valleys into unoccupied and marshy wastes. In the year 1836, however, most important changes were introduced, which will conspire with the wise and stringent measures passed by the present constitutional government to raise this fine island from the abyss into which bad government and worse laws had plunged it.

Feudal tenure and feudal jurisdiction have entirely been abolished; and lands have been declared to be the free property of individual owners, communes, or the crown. The latter is become the possessor of all waste lands, or such lands as neither individuals nor communes could show any title to. These crown-lands are sold or granted in *emphytheosis* by the government at a very low price, with a view of attracting population, capital, and industry into the island. There are, scattered over various districts of the island, nearly 510,800 hectares (1,262,200 English acres) of public lands to be sold, of which only 80,000 hectares (197,690 English acres) have some appearance of cultivation. There are, besides, 430,000 hectares (1,062,590 English acres) of communal lands not cultivated, most of which are also offered for sale. The government are empowered to sell 80 hectares (197 English acres) without any auction; but when a greater extent is demanded by a single person or a company, the formality of a public auction must be gone through. The average price at which these lands are being sold varies from 20s. to 32s. a hectare. So that land is to be obtained in an island of proverbial fertility in the Mediterranean Sea at the same price that lands sell in Australia.

Its insular position gives Sardinia some advantages in point of climate over the opposite coasts of Italy. The heat in summer is not so overpowering, and the winter is very mild, snow being rarely seen, except in the elevated districts. December and January are the finest months of the year, and February the most disagreeable. Spring bursts out in great luxuriance towards the end of March. But the great disadvantage of the Sardinian climate, in ancient as well as in modern times, is the unhealthiness of the lower regions in summer. The *intemperie*, as the malaria is called in the island, is somewhat different from the malaria of Italy and Greece; for although equally or more acrimonious in effect, it does not produce the swelled bodies and sallow skins which are the pathognomonic symptoms of the latter. Both diseases usually commence when the summer heat, assisted by slight showers, disengages the impure gases from the low grounds, and continue till the beginning of November, when the heavy rains have precipitated the miasma, and purified the air. But they differ, inasmuch as malaria is generally supposed to be weak in its effects unless imbibed during sleep; whereas *intemperie*, though worst at night, is dangerous at all times. Instances have been known of strangers landing for a few hours only, from Italian coasters, who were almost immediately carried off by its virulence; indeed, the very breathing of the air by a foreigner at night, or in the cool of the evening, is considered as certain a death in some parts as if he had swal-

lowed some poisonous drug. While the atmosphere is in this state, the natives never move abroad until an hour after sunrise; and they hasten home before sunset, carefully closing every door and window, or, if obliged to go out, carefully holding a handkerchief before the mouth. The extreme heat of the day is also carefully avoided, for they are apprehensive of the *colpo di sole*, or stroke of the sun, attributing its frequency and fatal effects to the malignancy of the *intemperie*.

It is agreed on all sides that fire is an excellent antidote to this evil; and it is recorded that the lords of Oristano were wont, during the unhealthy season, to burn large fires around the town every night, to rarefy the mephitic exhalations. Most of the people remove from the plains to the higher grounds on St John's day in June, when the air begins to be unsafe, although it does not become dangerous before August. Those who, from their circumstances, are obliged to remain, keep themselves well clad in thick woollens, to avert the ardent rays of the sun. Exertion, exposure to summer showers, and fatigue of every kind, are studiously avoided; and a spare but nourishing diet is adopted, with cool acidulated drinks.

It is remarkable that adults who have been accustomed to the insalubrious districts can remain during the summer with comparative impunity, whilst children and new comers are more likely to fall victims to the *intemperie*. As it is chiefly owing to the extensive marshes and lagoons at the mouths of the rivers, and in all the low coasts or level tracts, there can be no doubt whatever that its ravages will disappear in proportion as marshy districts are drained, the beds of rivers and torrents embanked, and cultivation extended in the island.

The manufactures in the island are in so rude a state that in a commercial view they scarcely require to be noticed.

The foreign trade of the kingdom, both by land and by sea, is yearly increasing. The following table of the number and tonnage of the mercantile navy shows that every year, from 1853 to 1856, there has been an increase in the size of the vessels, and in the number of sailors engaged in trade:—

	Ships.	Tons.	Sailors.
On the 31st Dec. 1853	3222	168,585	28,746
" " 1854	3174	175,744	30,782
" " 1855	2962	184,860	31,987
" " 1856	2934	197,924	33,370

It is remarkable that, whilst in 1855 the building of ships, as compared with the previous year, shows an increase of 9116 tons, in 1856 the difference reaches 13,064 tons. Of the total number of sailors employed in 1854, 11,398 were furnished by Genoa, 5936 by Chiavari, 4384 by Savona, 4011 by Spezia, 1619 by Oneglia, 1529 by Cagliari, and 1405 by Nice. The great emporium of the trade of the state is Genoa. The number of vessels, national and of other countries, which entered its port from 1850 to 1854 was as follows:—

Number and Tonnage of Vessels which entered the Port Genoa, 1850–54.

Years	National.		Foreign.	
	Ships.	Tons.	Ships.	Tons.
1850.....	5782	278,113	1603	205,752
1851.....	5937	301,463	2175	231,528
1852.. ...	5886	332,792	1830	239,758
1853 ...	5681	307,626	2152	467,905
1854.....	5544	349,918	2349	301,598

The other four tables here below annexed will give an

¹ So late as 1820 the whole island was divided into 376 fiefs, of which 188 belonged to six Spanish noblemen, who never visited the island.

Sardinia. idea of the state of trade in the kingdom. They come only so far down as 1856, as there are no later official returns published. The first of them, marked "General Trade," shows the amount of all imports and exports, whether for internal consumption or re-exportation, whether of national or foreign production. The second, marked "Special Trade," gives the amount of imports and exports merely for home consumption and of home produce. The third table shows the various articles of import and export, with their official valuation; and the fourth points out the different countries with which the Sardinian trade is carried on, and the respective degree of importance with regard to each country. It will be seen that the chief articles of importation are cotton (raw and manufactured), sugar, coffee, spices, and other colonial productions; wool (raw and manufactured), wheat (chiefly from the Black Sea), common metals (such as iron, steel, lead and copper), mercery, cheese and butter, salt fish, and tobacco. The most valuable article of exportation is silk, but it has little connection with maritime commerce. The greater part of it, which goes to other countries, is transported by land-carriage, in order to supply the manufacturers of France, Prussia, Belgium, Holland, and in some measure of England; for even to the latter country much is now sent by land through France, or by the Rhine. Oil is one of the greater productions exported from Genoa, after being collected there by means of the numerous coasting vessels with which the shores abound. The larger portion of this article is sent to England, where it is used by the wool-combers in the manufacture of cloth; but a considerable quantity of it is sent to Holland, and to the interior of Germany, where it is applied to the same purposes. The other chief articles of export are wine, brandy, oxen, cows, swine, mules, fruit, seeds, and vegetables. The commerce in grain is casual, depending in a great degree on the productiveness of the harvests at home and in Switzerland, to which latter country, when the domestic supply is insufficient, the corn from the ports of Odessa and Taganrog is transmitted through Piedmont. The countries with which the most important trade is carried on stand in the following order:—France, England, Lombardo-Venetian kingdom, Switzerland, United States, and Parma, Modena, and Tuscany. On the whole, the trade of Sardinia may be considered to be in a prosperous and thriving state.

The internal commerce of the country, as well as its land trade with the neighbouring states, has been greatly favoured by the excellent carriage roads and the railways opened within these few years. Two magnificent roads, passing over Mount Simplon and Mount Cenis, and well known to tourists, connect Turin with Switzerland; a road over the Maritime Alps, by the Col de Tende, connects it with Nice; and two roads over the Apennines with Genoa and Savona. Several high roads open communications between Sardinia, Lombardy, and the duchies of Parma and Piacenza; and a beautiful road along the shore from the Var to Sarzana, places all the cities of the Riviera in communication with each other, with the capital, with Milan, and with France and Tuscany. In January 1859 there were open for the public traffic the following railways:—From Turin to—Genoa, 167 kilometres long; Pinerolo, 38 kil.; Cuneo, 87 kil.; Susa, 53 kil.; Ticino, 109 kil.; from Genoa to Voltri, 15 kil.; from Alessandria to—Arona, 102 kil.; Stradella, 59 kil.; Acqui, 34 kil.; from Mortara to Vigevano, 13 kil.; from Tortona to Novi, 16 kil.; from Savigliano to Saluzzo, 15 kil.; from Culoz to St Jean de Maurienne, 106 kil.; from Chivasso to Ivrea, 32 kil.; from Santhià to Biella, 30 kil.; from Vercelli to Valenza, 42 kil.: in all 918 kil., or 570 English miles.

From the reign of Duke Emmanuel Philibert (1553–80), who abolished the political rights of the great feudal vassals, the government of the states of the House of Savoy became a purely absolute monarchy. The head of the state being the only source of law, not only all laws emanated from him, and were promulgated in his name, but he also abrogated them at his will, as well as all judgments and decisions of any judicial body. He had an unrestrained authority of imposing taxes, and the uncontrolled administration of the revenue. Even in the island of Sardinia, though the form of convoking its national assembly, composed of the three *Stamenti*, or orders—of the clergy, the nobles, and the representatives of the town—from the transfer of the island to the House of Savoy was sometimes resorted to for an augmentation of the taxes, yet the powers of the *Stamenti* had gradually been limited to objects only of a local and insignificant nature, and the government was as absolute as in the continental states.

In 1848, however, the unlimited powers of the sovereign were placed under proper restraints by a constitutional charter (*Statuto Fondamentale del Regno*) freely granted by the late King Charles Albert on the 4th of March of that year.

By this new constitution, whilst the executive power belongs exclusively to the king, the legislative power is collectively exercised by the king and by two chambers, an upper one, called *Senato*, and a lower one, called *Camera dei Deputati*. The upper chamber or Senate is composed of an unlimited number of members nominated by the king for life, from among persons at least forty years old, and belonging to one of the twenty-one categories spe-

cified by the charter. The princes of the royal family sit by right in the Senate at twenty-one, but do not vote till they are twenty-five years old. The number of senators at present is ninety-eight.

The Lower House, or Chamber of Deputies, is elective. A deputy must be thirty years old, and have the requisites established by the electoral law. The Chamber consists of 204 deputies, who are returned by a corresponding number of electoral colleges or districts, into which the kingdom is divided. Neither senators nor deputies receive any salary or indemnity. The duration of Parliament, unless a dissolution takes place before, is five years. The chambers meet annually, and in case of a dissolution of the Lower House, a new chamber must be summoned within four months. No tax can be imposed or levied which has not previously been assented to by the Chambers and sanctioned by the king. Each of the three powers of the state has the right of introducing bills, but all money bills must be introduced first in the Chamber of Deputies. The sittings of the Chambers are public. No sitting is valid unless an absolute majority of the members are present: the debates must be in Italian. The ministers of the crown are entitled to attend the debates and to address the houses whenever they deem it expedient; but they have no vote unless they are members of either house. The charter also declares the throne hereditary according to the Salic law; guarantees individual liberty and the liberty of the press,—the latter, however, subject to a repressive law; and establishes that judges, except those of *Mandamenti*, are irremovable after having exercised their functions for a period of three years.

The king's ministry consists of eight departments:—Presidency of the council; Foreign Affairs; Home; Grace and Justice; War and Navy; Finances and Commerce; Public Instruction; and Public Works. The public administration is carried out by an *Intendente Generale* and a Council in the capital of every division, an *Intendente* and provincial council in every province, and a *Sindaco* or mayor in every commune. A Council of state residing at Turin takes cognizance of appeals in all questions relating to administrative matters.

Justice is imparted according to the *Codice pel Regno Sardo* (which in substance is the Code Napoleon), and is administered by means of—1. Justices of the peace established in the *Mandamenti*. 2. Provincial tribunals residing in the capital of every province. 3. Several tribunals of commerce, residing at Turin, Genoa, Savona, Nice, and other cities. 4. Six courts of appeal, residing at Turin, Chambery, Nice, Genoa, Casale, and Cagliari; each court has two chambers, one for civil, and the other for criminal matters. A branch of the court of appeal of Cagliari resides at Sassari. 5. A court of cassation residing at Turin, which revises the judgments of the courts of appeal, and in case of a violation of the law, annuls them, and sends the parties before another court of appeal for a new trial. 6. A

Sardinia. *Regia Camera de' Conti*, or audit court, at Turin, with jurisdiction over all the accountable in the kingdom. 7. An Admiralty court at Genoa.

For military purposes the Sardinian states are divided into the five divisions of Turin, Genoa, Alessandria, Savoy, and Sardinia; and the two sub-divisions of Novara and Nice. The army bears a very high character, and by her gallant conduct in 1855 and 1856 earned praise from high military authority in our country. It is recruited yearly, in the continental possessions by means of a conscription, and in the island of Sardinia, which is exempt from it, by means of voluntary enlistment. Every conscript who does not avoid service by providing a substitute, or every volunteer who has enlisted, is bound to serve eight years, after which, on retiring, he is enrolled in the provincial battalion of his respective district, and for another period of eight years is liable to be called into active service in case of war. Without including the provincial battalions, the whole regular force of the kingdom in 1854, whilst on peace footing, numbered 47,524 men and 7602 horses. It was raised to more than 60,000 in 1855, when Sardinia, having joined England and France against Russia, sent 15,000 men to the Crimea as her contingent. In 1858 it numbered altogether 53,330 men, and was composed as follows:—

	No of Men.
Infantry.....	20 regiments
Sharp-shooters (<i>bersaglieri</i>) ..	11 battalions
Chasseurs (irregulars) ..	1 battalion
Cavalry	9 regiments
Carabineers, engineers, artillery, bodyguards, &c.
Total....	53,330

There were also twelve battalions of the National Guards. The carabineers answer to the French *gensdarmes*, and perform the service of the police.

The fleet in 1858 consisted of four sailing frigates, four steam frigates, four corvettes, three brigs, a schooner, ten steamers, and other small craft; in all, forty ships, carrying 900 guns, and manned by about 3000 sailors and marines. The stations were, Spezia, Genoa, Villafranca, and Cagliari.

According to the budget voted by the Chambers for the present year 1859, the revenue of the kingdom is set at L.5,816,430, 11s. 9d.; expenditure L.6,012,598, 16s. 6d.; thereby showing a deficit of L.196,168, 4s. 9d. Of late years there has always been an annual deficit, which has chiefly been caused by the outlay for the army, the formation of the naval station at Spezia, the repairs of the fortress of Alessandria, and the construction of railways and other public works; and has been met by an increase of the taxation. The national debt, which in 1847 was only of L.4,000,000 sterling, in 1856 had swelled to the sum of L.27,240,000, bearing interest for L.2,000,000 at 4 per cent., and for the remaining 25,240,000 at 5 per cent. Such a great increase in the course of less than nine years was brought on by an expense of nearly L.6,000,000, incurred by the state for the construction of the railways from Genoa to Turin, and from Alessandria to Arona; by the extraordinarily heavy expenses entailed by the war with Austria in 1848–49; and by a loan of L.2,000,000, contracted in 1856 to meet the expenses of the Crimean expedition. The subjoined table will give an idea of the various items of the revenue and expenditure. Here we shall only notice that about L.1,341,997, or more than one-fifth of the whole expenditure, and nearly one-fourth of the revenue of the kingdom, is absorbed by the payment of the interest on the national debt; and yet, on the whole, the finances of Sardinia may be considered to be in a satisfactory state; for though the expenditure has been steadily and yearly increasing since the establishment of a constitutional government, the revenue has equally increased in

proportion; and the country, owing to a much greater amount of production and a considerable development of commerce, caused by the liberal commercial policy of the present administration, has scarcely felt the corresponding increase of taxation.

By the constitutional charter, the Roman Catholic religion is the religion of the state, but perfect freedom of conscience is guaranteed to all existing dissenters. With the exception, however, of some 25,000 Protestants, well known by the name of Waldenses, and about 40,000 Jews, the inhabitants of the Sardinian kingdom all adhere to the Roman Catholic Church. The Waldenses, who have wonderfully withstood long, frequent, and cruel persecutions, are settled in the valleys of Luserna, Perosa, and San Martino, on the eastern slope of the Alps in the western part of Piedmont, between Susa and Nice. They have fifteen parishes, besides churches at Pinerolo, Turin, Alessandria, Genoa, and Nice; and a college of the Holy Trinity at Torre, near Pinerolo, in which their youths receive literary and theological education. The Jews are scattered over all the continental Italian states, and have twenty universities or synagogues of their own.

The Roman Catholic establishment is very extensive, comprehending no less than seven archbishoprics,—Turin, Chambery, Genoa, and Vercelli, on the continent; and Cagliari, Sassari, and Oristano, in the island; and thirty-five bishoprics, of which nine are in the island,—Galluri Nuovo, Iglesias, Ogliastro, Alghero, Ales, Ampurias, Tempio, Bosa, and Bisarcio; and twenty-six on the continent,—Maurienne, Tarantaise, Annecy, Aosta, Susa, Pinerolo, Acqui, Alba, Asti, Cuneo, Fossano, Ivrea, Mondovì, Saluzzo, Alessandria, Biella, Casale, Novara, Vigevano, Albena, Nizza, Bobbio, Sarzana, Savona, Tortona, and Ventimiglia. Besides the chapter of ecclesiastics attached to each cathedral, there are seventy-six collegiate churches with their respective chapters. Every see has a seminary for the education of the ecclesiastics. The island of Sardinia is divided into 381, and the continental possessions into 3872 parishes. The number of monks and nuns was very large; but by a law passed by the Chambers in May 1855 all religious and monastic orders were suppressed, with the exception of those actually employed in “preaching, teaching, or tending the sick.” On the carrying out of this law, it was found that the various religious orders affected by it were as follows:—

Sardinia.

	Continental States.				Island.

The education of the people, which formerly was little attended to, has of late attracted the attention of the government, and thereby made considerable progress. The kingdom is divided into the four academical districts of Turin, Genoa, Cagliari, and Sassari, with a university in each of those cities for the attainment of the higher branches of knowledge. The university of Turin, the most important of them, was founded in 1412, and is now very flourishing. It consists of five faculties: theology, with eight chairs; law, with fourteen; medicine and surgery, with fourteen; humanities, with twelve; and natural philosophy and mathematics, with fourteen. In each faculty there is a council of doctors, by whom the academical degrees are conferred. The number of young men who attended the various faculties in 1858 was reckoned at about 1300. In the provinces there are colleges and schools, in which young men are prepared for the university degrees; technical schools for artisans; and the seminaries already noticed, in which those intended for the church receive their education. By a law passed under the constitutional regime, every commune must provide teachers for the elementary education of both sexes; and the tables here annexed show the number of these elementary schools, the attendance at them, the total expenses for their support, as well as their steady increase from 1854 to 1857. They also show the number of private schools, and their decrease in proportion as public schools increased. It will be seen that in 1857 there still were 126 communes without any elementary schools for boys, and 1019 communes that had no schools for girls.

Number of Public and Private Elementary Schools, and of Communes without them, from 1854 to 1857.

Year.	Public Schools for Boys.			Public Schools for Girls.			Private Schools.

The salaries of the teachers average—to men L. 16, to women L. 13 per annum.

Of the teachers at all these schools, 2854 were in 1854 ecclesiastics, and 2510 laymen; and in 1857, 3055 belonged to the former, and 3917 to the latter class. In 1848, out of a population of 4,916,087, there were able to write and read 754,309 men and 323,535 women; and able only to read 195,504 men, and 230,899 women. The lowest state of education was in the island of Sardinia, in which, out of 547,112 inhabitants, there were able to write and read 68,484 men and 4238 women; and only to read, 2928 men, and 3082 women. The returns of the last census, when published, will no doubt show a very considerable improvement, especially in the continental possessions; for in the town of Turin alone, which in 1848-49 had only 22 public elementary schools, with a yearly expense of 43,362 francs (L. 1734, 10s.), in 1857-58 there existed 174 schools, the support of which cost altogether 275,000 francs (L. 11,000). Such are some of the blessings that a constitutional government has bestowed upon Sardinia.

The kingdom is divided into fourteen administrative Divisions, of which eleven include the continental possessions, and three the island of Sardinia. Each division is divided into Provinces, each province into districts called *Mandamenti*, and each mandamento into Communes; a commune sometimes consists of several villages. There are altogether 50 provinces, 502 mandamenti, and 3088 communes. There is a regular census taken every tenth year on the 31st of December. As the detailed official returns of the last census, taken on the 31st December 1857, have not yet been published, the following table will show the extent of each province, its population, and that of its chief town, the number of mandamenti into which it is divided, and of the communes in each mandamento, according to the returns of the census taken in December 1847. It will also show the population of each administrative division as returned in December 1857. Of the island of Sardinia, which has not yet been regularly surveyed, there is only given the supposed area of the whole, with the dependent smaller islands. The name of the capital, when it differs from that of the province is also given, as well as the names of the other towns in the kingdom with a population of more than 6000 inhabitants.

Sardinia.

The population for the last thirty years has steadily though slowly increased. Thus the *Stati di Terra Ferma*, which in 1838 had 4,125,735 inhabitants, in 1848 had 4,368,975, and 4,590,260 in December 1857. The variations in the population of the island of Sardinia were greater. In 1775, 426,375; in 1800, 361,445; in 1809, 359,344; in 1815, 362,405; in 1828, 436,357; in 1838, 496,205; in 1848, 547,112; and in 1858, 577,282. The great fall of the population from 1775 to 1800 has never been well accounted for; and it is remarkable that the decrease continued even after the island had become the residence of the royal family, on the occupation of the continental possessions by the French. According to the census of 1838, which is taken in preference, as its returns were not in any way affected by revolutions or wars, the *Stati di Terra Ferma*, on the 31st December 1837, were inhabited by 2,072,707 men and 2,053,028 women. In the course of that year there had been 306,902 marriages, 1,303,250 deaths, and 1,457,493 births, of which 30,474 illegitimate, —the average of illegitimate being 2·09, and that of legitimate births 97·91 per cent. The maximum of natural children is of 3 per cent. at Turin, and the minimum is of 1·03 per cent. in the province of Alessandria. The maximum of births takes place in the following order:—March, April, January, October; the minimum in June and December. The greatest number of marriages take place in February, January, April, November; and the smallest number in December and March. Out of their total number in 1837 there had been in February, 62,188; January, 47,022; April, 32,108; November, 26,131; March, 13,053; December, 10,054. With regard to age, the greatest number marry from 20 to 25 years old. In 1837, 23 men and 288 women had married from 12 to 14, and 4052 men and 949 women more than 56 years old. The maximum of deaths occurs in February and August; the minimum in June and October. An idea of the longevity in the continental possessions may be formed from the following numbers:—Out of 1,303,250 deaths that occurred in 1837, 15,734 were still-born; 158,542 died before they were a month old; 152,843 from 1 month to 1 year old; 95,333 from 1 to 2 years old; and so on, decreasing to the minimum of 5130 from 12 to 13 years old; 92,956 had died from 50 to 60; 121,665 from 60 to 70; 100,614 from 70 to 80; 39,274 from 80 to 100, and 362 more than 100 years old.

Little is known of the early history of the various states which now form the continental possessions of Sardinia before they fell under the Roman power. From that time they followed the fate of Rome, and eventually were overrun by the various northern nations that overthrew the empire. Most of the territories south of the Alps, in the sixth century, fell under the Longobards, in whose history the dukes of Ivrea, of Asti, of Aosta, of Turin, &c., play an important part. When Charlemagne put an end to the Longobard kingdom the country fell under the sway of several small counts, dukes, and marquises, who, sometimes as vassals of the empire, sometimes asserting their independence, succeeded in holding possession of it till they were gradually swept away by a more able, more powerful, or more fortunate one of their number, and their petty states absorbed into a monarchy.

The House of Savoy is one of the most ancient sovereign families in Europe. Its earliest historical progenitor, and the founder of its power, was Umberto Biancamano, or Whitehand (flour. 1003–1045), a liege baron of the Burgundian kings, and a descendant, according to some genealogists, of Berengarius II., Marquis of Ivrea and King of Italy; and according to others, of Louis the Blind, King of Provence and Italy, and emperor. Umberto's original possessions seem to have been the county of Salmonrec in the Viennois, to which eventually he added the counties of

VOL. XIX.

Sardinia.

Noyon and Bellay, the Chablais, the Maurienne, the Tarentaise, Savoy, and Aosta. Rudolph III., at his death without issue in 1032, having appointed his joint heirs his widow Ermengarda and Conrad the Salique, the Burgundian Barons refused to comply with his will, and asserted their independence. Umberto alone remained faithful, and having led an army by the valley of Aosta across the Alps, enforced obedience to the widow and to Conrad. This act of chivalry strengthened the foundation of his power. His son Odo, by marrying Adelaid, only offspring of the royal family of the Liarduns, added the county of Turin and great part of the surrounding country to his paternal states. The power of the House of Savoy was established. Ever since, through the course of eight centuries—through many vicissitudes of fortune, such as at times had nearly brought it to its total ruin—the House of Savoy has gone on slowly, but steadily gaining power and influence; and whilst all the other great mediæval Italian families, such as the Estes, the Gonzagas, the Viscontis, the Sforzas, the Carraias, the Medicis, have disappeared, the descendants of Umberto Biancamano are still powerful and flourishing. As it is not consistent with the plan of this work to give a regular history of the Sardinian states, we shall confine ourselves to a short notice of the principal events by which they were gradually brought together into a monarchy.

The reign of Charles III., in the beginning of the sixteenth century, was a period of great misfortunes for the House of Savoy. The progress of the new religious opinions tore away from his possessions the Canton de Vaud, Geneva, and the lower Valais, and deprived him of the alliance of Berne and Fribourg. During the contests between Francis I. of France and the Emperor Charles V., Duke Charles III. having attended the coronation of the emperor at Bologna, Francis invaded Piedmont, and, by a royal edict of February 1537, declared it a French province, which had been unlawfully detached from the kingdom. Charles died in misery at Vercelli, attended only by his barber, in 1553. Emmanuel Philibert (1553–80), the heir to the ducal crown of Savoy, was living in poverty at the court of Charles V.; but he was a man of great energy of character, of an iron will, and of remarkable military talent. The battle of St Quintin is well known in history. By the treaty of Chateau Cambresis that followed it, Emmanuel Philibert, to whose wisdom and valour the Spaniards chiefly owed their victory, recovered all the possessions of his ancestors, and was the second real founder of the greatness of his house. One of his most important measures was that of abolishing political feudality, and, by substituting a fixed annual payment in money instead of the military service of the great vassals, forming a stipendiary regular infantry, which enabled him to restore order in the country, and to defend it from foreign enemies. His successors in the dukedom were Charles Emmanuel I. (1580–1630), Victor Amadeus I. (1630–37), Francis Hyacinth (1637), Charles Emmanuel II. (1638–74), and Victor Amadeus II. (1675).

The latter sovereign, who during his long reign (1675–1730) was almost constantly at war with France or Spain, was the first king of Sardinia. On the breaking out of the war of the Spanish succession in 1700, at first he followed the part of the French; but, indignant at the treatment he met with from Louis XIV. and his generals, for a whole year he took no part in the war. But at length, tempted by the offers of the allied powers, Austria, Holland, and England, in 1703 he declared himself against France. After many reverses, which had nearly deprived him of all his possessions, finally the battle of Turin, won by the imperial army under the command of Prince Eugene of Savoy on the 7th September 1706, compelled the French to raise the siege of his capital and retire from Italy. By the treaty of Turin of March 13, 1707, all the possessions which the

4 M

Sardinia. French held by virtue of the rights and in the name of Spain in Italy, were surrendered to Austria; and the latter power ceded to Victor Amadeus, as the price of his co-operation, the Lomellina, the Montferrat, the district of Alessandria, and the Valsesia. The power of the House of Savoy was thus extended into Lombardy, which Victor Amadeus used to compare to an artichoke that was to be eaten leaf by leaf. At the final end of the war, by the peace of Utrecht in April 1713, and the treaties of Rastadt and Basle in March and September 1714, Spain gave up the island of Sardinia to the emperor, and the island of Sicily to Victor Amadeus, who thereupon assumed the name of King of Sicily. This arrangement, favourable to the House of Savoy, was due chiefly to the influence of England.

But at the death of Louis XIV., Spain, which was then governed by Cardinal Alberoni, tried by going to war to recover her losses, and at once re-took possession of Sicily and Sardinia. The quadruple alliance formed against her compelled her in 1720 to a peace, by which the House of Austria retained Naples, and had Sicily added to it, and the island of Sardinia was given to the House of Savoy, to make up for the loss of Sicily. From that time the dukes of Savoy became kings of Sardinia.

The early history of this island is wrapped up in darkness, and the accounts that the ancient writers have left us of the origin of its first settlers are extremely various and conflicting. But whatever may be thought of them, the high antiquity of its settlement is attested by durable monuments, the materials, height, and construction of which are different from almost any other that are to be found. These Cyclopean structures are very numerous, more than twelve hundred of them having been found and recorded in the island. They are called *Nuragis* both by ancients and moderns, being in height about 50 feet, and in diameter at the base about 90 feet. They are strong buildings, in the form of a truncated cone, composed of masses of stone from 2 to 5 or 6 feet square, arranged in layers without cement. The materials are lava, freestone, porphyry, or such other substances as the respective sites afford; and they generally crown the summits of hills commanding plains, where they are seen in every state, some being nearly complete, and others a mere heap of rubbish. On entering these edifices, which is effected by a low door, the structure is found to extend below the surface of the surrounding earth. The interior space is almost invariably divided into two floors, each consisting of a vaulted room, to which access is gained from a ramp between two concentric walls, and leading to the summit, where a flight of steps completes the ascent. The *nuragis* are of two distinct kinds. Those which are the most common have no marks of the chisel, and are constructed of massive blocks with irregular faces, and smaller stones in the interstices; the materials of the others exhibit exteriors formed by tools, though the stones are not exactly square, but are placed with a stricter regard to keeping the horizontal layers, and gradually diminish in size towards the summit.

There have been various conjectures respecting the probable object of these buildings. The darkness of their interior, and the fragments of *terra-cotta* found in them, would indicate their having been monuments for the dead; a belief so general that they have obtained in their neighbourhood the name of *Domu de Orcu*, or the house of death; but the pottery being evidently Roman, and in some instances accompanied by coins of the lower empire, indicates only that such was the use made of them at a late period. Captain Smyth, who examined these ancient monuments, says, "From their laborious construction, their number, and their general situation on *curcureddus*, or eminences, more or less distant from each other, I cannot but suppose they were designed to answer the double purpose of mausolea

for the eminent dead, and as asylas for the living, especially as many of them are flanked with smaller *nuragis* having a subterraneous communication. But the mystery in which they are involved will probably remain impenetrable, since none of them exhibit the least trace of either literal or symbolical characters."

At whatever periods these remarkable works were erected, a long time elapsed before any precise notice is to be discovered of the history of Sardinia, until about the year 500 before Christ, when the Carthaginians under Malchus, after a victorious campaign in Sicily, attempted the conquest of the island. They were repulsed with such loss, however, as left it in repose for some time; but at length the Carthaginians succeeded in gaining a footing and maintaining themselves in the island, till they surrendered their claims over it to the Romans, B.C. 238. The latter, however, did not effect its subjugation till after several campaigns.

At the fall of the Roman empire, Sardinia, by successive conquests, passed into the hands of the Vandals, the Saracens, and the Spaniards, in whose power it remained from 1324 till they lost it, as has already been noticed, during the war of the Spanish succession.

The war of the Polish succession (1733-38), which caused important changes in Italy, brought to the House of Savoy Tortona and Novara; and by the war of the Austrian succession, on the death of the Emperor Charles VI., Sardinia gained the districts of Vigevano and Bobbio, which Maria Theresa ceded to Charles Emmanuel in reward for his services.

Such was the state of Sardinia when the French attacked it in 1792. In 1798 their successes were such as to compel the king, Charles Emmanuel IV., to abandon the capital, Turin, and the whole of his continental dominions. He withdrew to Leghorn, where he received with delight deputies from the *Stamenti* of the island of Sardinia, assuring him of the entire devotion of the people to his person and government. Satisfied with these assurances he embarked, and, escorted by an English frigate, arrived at Cagliari on the 3d of March 1799, where he was enthusiastically welcomed.

The successes of the Russian general Suwarof induced his majesty to return to the Continent, till, hearing while in Tuscany of the battle of Marengo, and being inconsolable for the death of his wife, the sister of Louis XVI., he abdicated in favour of the Duke of Aosta in March 1802, and resided in privacy at Rome, where he died in 1819. His successor, Victor Emmanuel, remained some time in Italy, in the hope of gaining his continental dominions; but seeing little prospect of succeeding, he left Naples, at which place he had resided since his accession, and arrived in Sardinia on the 17th of February 1806, where he remained secure under the protection of England.

The son of Charles Emmanuel followed the footsteps of his father in opposing the principles of the French revolution, which was then spreading its effects over all Europe, and nowhere more generally than in the continental part of the kingdom of Sardinia. The events of that period are to be found narrated in this work in the historical part of the article FRANCE. We need only state here, therefore, that the King of Sardinia returned to his continental capital in 1814, and by the treaty of Vienna the duchy or ancient republic of Genoa was added to his dominions. By the same treaty he ceded to the state of Geneva the circles of Carouge and Chesne, containing 12,700 inhabitants.

Victor Emmanuel on his restoration re-established, as far as could be done, the old order of things, except that he confirmed the purchases of confiscated property made under the French, restored to the former owners only the few estates that had not been sold, and allotted an annual sum of L.16,000 as some compensation to those whose property

Sardinia.

sardinia. had been plundered. But he became a zealous member of the Holy Alliance, again introduced the Jesuits, established a very severe censorship of the press, and introduced such restrictions on the process of education in the universities and the colleges and seminaries as he judged advisable to check the prevailing tendency to infidelity and immorality. These measures, combined with the general state of Italy, caused in 1821 an insurrection, the particulars of which, as well as a summary of the events of 1848, and the establishment of a liberal constitutional government in the country, are given in this work under ITALY.

The liberal institutions granted by the late King Charles Albert in 1848, have been maintained by his son and successor, the present King Victor Emmanuel; and during the last seven years the country, under a wise and enlightened administration, has made great progress in agricultural improvements, in commerce, in general wealth, and in education.

Such was the state of Sardinia in January 1859. Since that time important events have happened, which seemed to endanger, not only her constitutional liberties, but even her very existence as an independent power. The gigantic struggle that for two months strewed the plains of Northern Italy with human bodies, has just come to an end; but its results being dependent upon a peace, the real terms of which are still wrapped up in mystery, and are at this moment being arranged at Zurich, we shall only give here a very rapid sketch of the causes and the course of the war we have recently witnessed.

Ever since the conclusion of the disastrous war with Austria in 1848 and 1849, the relations between Sardinia and that country, far from being on a friendly footing, had been such as to lead at last to an interruption of diplomatic relations. For an explanation of their hostile attitude, we must go back, at least, to 1815; since which time, whenever an attempt was made on the part of any of the Italian States for freedom—as in 1820 at Naples, and in Piedmont; and in 1830 in the Legations and the Duchy of Modena—the iron hand of Austria interposed, and re-established the stringent despotism of previous governments. It was either at the direct bidding of Austria—as in Tuscany, Parma, and Modena; or by Austrian counsel, countenance, and support—as in Naples and the Papal dominions,—that the constitutional charters, granted in 1848, were, in the course of 1849 and 1850, suppressed, and a despotic and reactionary policy resorted to.

Sardinia alone, after 1848, preserved her liberal institutions, and fairly worked out a regular constitutional government. Hence her very position as a free state, in direct antagonism to the military despotism by which the Lombardo-Venetian kingdom was swayed, became a standing menace to Austria. The feeling of nationality, and the liberal aspirations of the Italian subjects of the latter power, not only were kept alive by the constitutional liberties thriving in a neighbour Italian state, but found expression and sympathy, and were constantly fanned by the free Sardinian press, which never failed to register and expose any general act of despotism, or any instance of individual wrong and oppression, exercised by the Austrian rulers of Lombardy and Venice. For the attacks by the press Austria often demanded redress from Sardinia; and was uniformly answered, that the press being free by the constitution, the government had no control over it; but if the newspapers made false statements, they might be prosecuted for libel. Many Lombards and Venetians, to escape persecution after 1849, availing themselves of the permission to expatriate given by the Austrian laws, had established themselves in Sardinia, where some of them even sat in the Chambers, or filled high official situations. It was in the nature of things, that as Austria was the countenancer and supporter of the despotic rulers, so the con-

Sardinia. stitutional party, all over Italy, should look up to Sardinia as their representative and leader, and the power by which they might expect a voice to be raised in their behalf.

Under such circumstances it was evident that Austria would never have a peaceful supremacy in Italy, so long as a constitutional government existed in Sardinia; and that, on the other hand, the liberal institutions of the latter country were constantly in danger of being trampled upon by the former, whenever a favourable opportunity occurred.

This state of things had almost daily been growing worse, when a few significant words of menace offered by the French emperor to the Austrian ambassador, at Paris, on New Year's day, 1859, accelerated a crisis, which otherwise would have been only delayed, not avoided. Austria, suspecting the existence of an accord against her between France and Sardinia, poured a formidable force into Italy, and assumed a threatening attitude towards the latter power, by bringing a division of her army up to the frontier, on the Ticino, and by strongly fortifying and garrisoning Piacenza, in the duchy of Parma.

Sardinia protested against the Austrian movements, especially against the fortification and occupation of Piacenza, contrary to the treaties of 1815. At the same time she made preparations for defence, and applied to France and England for assistance, in case of attack. The relations between France and Sardinia grew at this time closer, by means of a marriage between Princess Clotilde, a daughter of King Victor Emmanuel, and Prince Louis Napoleon.

Our government, under Lord Derby's administration, endeavoured to bring the parties to an understanding; and to that effect Lord Cowley, from the embassy at Paris, was sent by Lord Malmesbury on a special, but, as it turned out, fruitless mission to Vienna. It was proposed that Austria should give up the separate treaties she had made, since 1815, with the smaller Italian powers, and should withdraw from the Duchies and the Legations. The efforts of England were, in a certain way, thwarted by the proposal of a congress by Russia. But the rather too favourable attitude we assumed towards Austria, by raising a hope, that, in case of war, we would eventually join her, may possibly have tended to induce her to take the step which finally led to the rupture of peace. For whilst arrangements for a pacific solution of the difficulties were still going on, Austria addressed to Sardinia a peremptory summons to disarm within three days. The Sardinian government having answered, that though it was unreasonable for the strong to ask the weak to disarm, yet they would abide by the decision of France and England. After a few days, at the end of April, the Austrian army, in three bodies, crossed the Ticino, and invaded the Sardinian territory.

Had Count Gyulai, the Austrian commander-in-chief, pushed on with the greatly superior force he had, the Sardinians would scarcely have been able to cover Turin; and they were so much prepared to give it up, if necessary, that the state archives had been removed to Chamberg. But before the arrival of the French, the Austrians lost an invaluable time in comparative inaction, and in exacting heavy, and almost marauding, requisitions of provisions of every kind, and money, in the provinces of Lomellina, Vercelli, and Novara.

Meanwhile a large French force, which was sent on the first news of the Austrian summons, began to pour its numbers into Italy, across the Mont Cenis and the Mont Genevre, and by Genoa, in aid of the Sardinians; and, on the 12th of May, the French emperor himself landed at the latter place, and assumed the command-in-chief of the French and Sardinian armies.

An imperial manifesto promised the independence of Italy, from the Mediterranean to the Adriatic Sea; and for

Sardinia. a time it seemed as if the promise was to be fulfilled. In less than two months from the commencement of hostilities, the Austrians, beaten in every encounter, were driven back from the Sesia and the Po, beyond the Mincio.

The main body of the French army assembled at first round Alessandria. Large forces were afterwards concentrated on the right, and seemed to aim at Piacenza, and forcing a passage of the Po, between that fortress and Pavia. An endeavour of the Austrians to dislodge them from their position led, on the 20th, to the battle of Montabello. The French were reposing within their lines, when, at 11 A.M., the Piedmontese outposts gave the alarm. A Sardinian cavalier, covered with blood and dust, galloped into the French camp, calling out, "To arms! the Austrians!" A detachment of Sardinian cavalry, under General Sonnaz, and two French battalions of the line, commanded by General Forey, had to sustain for hours an unequal combat against overwhelming forces. At length, strong French reinforcements having been brought up from Voghera, the head-quarters of Marshal Baraguay D'Hillier's division, the Austrians, after a sanguinary struggle of six hours' duration, were repulsed, driven out of Montabello, and, fairly beaten, retreated to Casteggio.

After several skirmishes on the 31st, the main body of the French army crossed the Po at Casale, and took the road to Vercelli, where the passage of the Sesia was carried out by the successful action of Palestro, to cover their rapid march on Novara. At the same time, two actions, gallantly fought by the Sardinians, made the Austrians believe that the French were marching on Mortara, in the centre of their line.

By these strategic movements the allies outflanked the right wing of the Austrian army. On the 2d of June, General M'Mahon, with his division, threw a bridge over and crossed the Ticino at Turbigo, and marched towards Magenta, on the road to Milan; whilst the emperor, with other army corps, advanced towards the bridge of Bufalora.

The Austrians having learned, on the night of the 2d, the passage of the Ticino at Turbigo, rapidly sent across that river, at Vigerano, three army corps, and on the 4th opposed at once the passage at Bufalora, and attacked M'Mahon's division at Magenta. A fearful struggle took place, in which the troops on each side engaged in the action exceeded 100,000 men. After a sanguinary conflict, which lasted more than eight hours, during which the Imperial and Sardinian guards took and retook the position six times, at half-past eight P.M. the allies remained masters of the field of battle; and the Austrians, who, according to the French accounts, had 15,000 killed and wounded, withdrew, leaving 4 guns, 2 flags, 5000 prisoners, 12,000 muskets, and 30,000 knapsacks. The loss of the allies was put down at 4000. Two French and one Austrian general fell in battle. General M'Mahon, to whom the victory was chiefly owed, was created a field-marshal and Duke of Magenta.

This victory was followed up by another signal success at Melegnano, from which place Marshal Baraguay D'Hilliers, on the 8th, dislodged bodies of Austrian troops that had entrenched themselves. The Austrian loss was estimated at nearly 2000; the French at 943, among whom were 69 officers.

The Austrian accounts, which admitted a loss only of 5000 men at Magenta, greatly deprived the action of its former proportions, and represented it more like a drawn battle than a victory. Its great importance, however, was proved by its practical results. In conjunction with the brilliant action of Melegnano, not only it opened the way to Milan to the allies, but it cleared Lombardy of the Austrians; at first, as far as the Adda, and afterwards the Mincio. Pavia, Brescello, Pizzighettone, and Piacenza,

were hastily evacuated; and the great fortifications, constructed at the latter place with so much labour and expense, which gave one of the pretexts for the present war, were destroyed. In every direction the Austrians fell back upon their reserves in the fortresses beyond the Mincio. They precipitately retired even from Ancona and Bologna, in the Papal States, which they had occupied since 1849.

On the 8th of June, the day of the battle of Melegnano, Napoleon III. and Victor Emmanuel entered Milan, among the enthusiastic greetings of the inhabitants.

On the same day, by a proclamation to the Italians, Napoleon III., after disclaiming any view of personal ambition, or enlargement of the territory of France, and only claiming the moral influence of contributing to render free one of the most beautiful parts of Europe, invited them all to unite in one sole object, the enfranchisement of their own country. "Form a military organization," he continued: "hasten all of you to place yourselves under the flag of King Victor Emmanuel, who has already so nobly shown you the path of honour. Remember, that without discipline there is no army; and, animated with the sacred fire of justice, be nothing to-day but soldiers. To-morrow you will be free citizens of a great country."

The Austrians, under General Count Schlick, the successor of Gyulai, who was deposed in consequence of the defeat of Magenta, continued their retreat along the north bank of the Po, within the quadrangle of the fortresses of Peschiera, Verona, Mantua, and Legnano; and the allies, keeping the northerly road, crossed the Adda and the Oglio without opposition.

On the 22d of June, the hostile armies had come so nearly face to face, as to make it evident that a great battle was imminent. The allies were encamped between the Chiese and the Mincio, occupying Lenato, Castiglione, and Montechiaro; and having their left wing resting on the high ground near Brescia and the southern end of the lake of Garda. At their extreme left was General Garibaldi, who, with the Cacciatori della Alpi, a body of volunteers, after a most daring and brilliant series of manœuvres round the extreme northern frontiers of Lombardy, had come down on the Lake of Garda. The Austrian forces were on the left bank of the Mincio, resting with their right on Peschiera and Verona, and with their left wing on Mantua.

On the 23d, the Austrians poured out their numbers from Mantua, Verona, and Peschiera; and, led by their young emperor, Francis-Joseph, who had assumed the command-in-chief, in the course of the evening crossed the Mincio at four different places, confident of defeating the allies, and driving them beyond the Chiese.

On the 24th, one of the bloodiest battles on record took place. The Austrians began the attack at daylight; and at 10 A.M. the whole of the two armies had come into collision. The battle lasted fifteen hours, and extended along a line of nearly 18 miles, from the neighbourhood of Brescia down towards Mantua. The right wing of the Austrians occupied Pozzolengo, where they met the Sardinians; their centre was at Caviana and Solferino, whilst their left wing marched on Guidinolo and Castel Goffredo, and for a time succeeded in repulsing the French.

The day was decided by a concentrated attack, made about three o'clock P.M., by the French Emperor on Solferino, a village in a commanding situation, where the Austrians had fortified themselves. After several hours of desperate fighting, the place was carried by the French, who, thereby breaking the Austrian centre, moved large masses against their left wing, which, having pushed on almost to the Chiese, was in danger of being surrounded and cut out. Late in the evening, the young Emperor of Austria, with tears in his eyes, saw that the day was irrecoverably lost, and gave the order for the retreat beyond the Mincio, which was accomplished under the protection

Sardinia.

Sardis. of a violent storm, that had begun to rage since three o'clock in the afternoon.

Few battles, in modern history, have been marked with more slaughter and horror. More than 300,000 human beings were brought into a close fight, and at night 35,000 of them, at least, were dead or dying. The French, according to their own statement, had 12,720 killed and wounded, and the Sardinians 5525. The Austrian loss, which was put by them at 11,213, is generally asserted to have exceeded 18,000. Numerous prisoners, 13 pieces of cannon, 2 flags, and large quantities of arms and ammunition, fell into the hands of the allies; and Napoleon III. slept at Solferino, in the very apartment which, the previous night, had been occupied by Francis-Joseph.

After the battle of Solferino, the command-in-chief of the Austrian army was given to Baron Hess, who offered no opposition to the passage of the Mincio by the allies. On the 1st of July, the latter received a reinforcement of 35,000 men, brought by Prince Napoleon through Florence and Modena.

Whilst the Sardinians were investing Peschiera, a French division was at Goito to watch Mantua; Garibaldi's *Cacciatori dell'Alpi*, supported by General Cialdinè's division, were moving to close up the valley of the Adige; and the emperor, with the main body of the army, was approaching Verona,—the startling news was received that Napoleon had sent an aide-de-camp to ask for an armistice; and that, on the 7th July, an armistice was actually concluded between him and Francis-Joseph, and commissioners already appointed to agree upon its terms. Events took at once a pacific turn. On the 11th, the two emperors met at Villafranca, and signed a peace, the basis of which were thus vaguely announced:—

"Italian Confederation under the honorary presidency of the Pope.

"The Emperor of Austria cedes his rights to Lombardy to the Emperor of the French, who transfers them to the King of Sardinia.

SARDIS, or **SARDES**, anciently the capital of Lydia, in Asia Minor, stood at the foot of Mount Tmolus, now called Bozdag, in a beautiful plain, about 50 miles N.E. of Smyrna. It was an ancient town, and built at first in a rude manner, so as to be very liable to conflagrations; but the citadel on a steep rock was almost impregnable, being fortified by three walls. It was thus enabled to hold out when the lower town was taken by the Cimmerians in the reign of Ardys. Under Cræsus, the last of the Lydian monarchs, Sardis rose to a high degree of prosperity; and after his fall in 546 B.C., it was the residence of the Persian satraps of Western Asia. During the Ionian revolt, B.C. 501, the insurgents, aided by the Athenians, took the city; and on that occasion it was accidentally set on fire and burned to the ground. Sardis was rebuilt; but its burning was the chief event that called down the indignation of the Persians against Athens, and led to the Persian wars with Greece. The city remained under the Persian empire till the time of Alexander the Great, to whom it opened its gates after his victory at the Granicus. After the battle of Ipsus, B.C. 301, Sardis fell to the kingdom of Syria; and when the two Scipios conquered Antiochus at Magnesia, B.C. 190, it became a part of the Roman empire. As we learn from the Book of Revelation, a christian church was early founded at Sardis, and was one of the seven to which that book was addressed. The city continued wealthy and powerful till the fall of the Byzantine empire; it was taken by the Turks in the eleventh century, but suffered a severer blow from Tamerlane, who almost entirely destroyed it about 200 years later. The ruins, though covering a large space of ground, are not

"The Emperor of Austria preserves Venice; but she will form an integral part of the Italian Confederation.

"General amnesty."

The intelligence of the peace, and its terms, were received with bitter disappointment in Italy; and no where more, perhaps, than in Tuscany, Parma, Modena, and the Legations. From the beginning of the war those states had overthrown their despotic governments; and, encouraged by the French Emperor's proclamations, had declared their wish of joining in the war against Austria, and uniting themselves to Sardinia. The peace of Villafranca threatened them with a restoration of their despotic rulers.

As it has already been stated, the real terms of the peace are at this moment being settled at Zurich, among the envoys of Austria, France, and Sardinia. In the meantime, at Parma, at Modena, at Bologna, and at Florence, representative assemblies have been summoned, which have expressed the national wish of resisting any attempt to re-establish their previous governments, and of placing themselves under Victor Emmanuel. On the 3d September, a Tuscan deputation presented to Victor Emmanuel, at Turin, an address, stating the unanimous proclamation by the Tuscan Assembly of the will of Tuscany to form part of an Italian kingdom under his constitutional sceptre. The king replied, that the accomplishment of their wish could only take place by negotiations, which were about to begin, on the affairs of Italy; that he would second their desire, and support it before the European powers, especially before the French Emperor, who had done so much for the Italian nation.

Whether, and on what terms and conditions, Lombardy will really be annexed to Sardinia; and whether Tuscany, Parma, and Modena, will eventually form part of the constitutional kingdom of the descendant of Umberto Biancamano, the lapse, possibly, only of a few months will show. At the present moment (September 1859), everything is in a state of great confusion and uncertainty. (***)

very interesting; in the middle of them stands the modern village of Sart.

SARDONIC LAUGHTER, a peculiar convulsive action of the diaphragm, giving the appearance of ghastly and unnatural laughter, and which is the closing symptom of several fatal diseases, is said to have been first observed in those who ate the herb *Sardonia*, a plant said to belong to Sardinia.

SARDONYX, a precious stone, consisting of a mixture of the chalcodony and carnelian, sometimes in strata, but at other times blended together.

SAREPTA, a fortified town of European Russia, in the government of Saratov, near the confluence of the Sarpa and the Volga, 15 miles S. of Tzaritzin. It was founded in 1765 by a colony of the Moravian brethren, and contrasts favourably with most of the Russian towns in this region, having straight streets, lined with neat white houses, and meeting in the centre in a fine market-place, adorned with a fountain. Cotton, silk, and woollen fabrics are manufactured here, as well as hosiery, tobacco, and snuff. The surrounding country has been brought by the labours of the settlers into a most flourishing condition, with rich fields, gardens, and meadows. Pop. about 4000.

SARI, or **SAREE**, a town of Persia, capital of the province of Mazanderan, about 11 miles from the shore of the Caspian, and 115 N.E. of Teheran. N. Lat. 36. 30.; E. Long. 53. 10. It is about 2 miles in circuit, surrounded by a mud wall and moat, with brick towers. There are several gates, but most of them have fallen down, and roads have been made through the wall at various other places. The houses are of brick, neatly tiled, and some of the

**Sardonic
Laughter**

Sari.

Sarlat

||

Sarno.

streets are good, though others are unpaved and very muddy. Everywhere marks of ruin and neglect are apparent. The most remarkable building is a hollow tower of brick, with a conical roof, 100 feet high. There are also a mosque, palace, five colleges, several Parsee temples, baths, and a mean bazaar, where there is some trade in the produce of the country. The surrounding region is fertile, and contains many saints' tombs. Pop. 30,000.

SARLAT, a town of France, capital of an arrondissement in the department of Dordogne, in the valley of the Sarlat, amid steep barren hills, 32 miles S.E. of Périgueux. It is encircled by old walls, and consists for the most part of narrow streets, lined with old ill-built houses. The best of the edifices are the ancient parish church, the college, and the hospital. Sarlat is the seat of law-courts, and has manufactures of paper and walnut oil. It was formerly a place of some strength, and has sustained several sieges. Pop. (1856) 6223.

SARMATIA, the name given by the ancients to an extensive tract of country lying to the east of the ancient Germania, bounded on the N. by the Baltic and the unknown country to the E. of that sea, E. by the Volga (*Rha*) from its confluence with the Kama to its mouth, and by the Caspian Sea, S. by Mount Caucasus, the Euxine Sea, and Dacia, and W. by the Vistula. It thus included eastern Prussia, parts of Poland and Galicia, and the whole centre and south of European Russia. All this country is now included within the limits of Europe; but as in ancient times the arbitrary boundary between the two continents was formed by the river Don (*Tanais*), Sarmatia was divided into European and Asiatic; the former lying to the west, and the latter to the east of that river. This vast region was occupied by a great number of warlike nomadic tribes, whose names are given by ancient writers, but whose respective localities are for the most part merely matters of conjecture. The history of Sarmatia presents us with no event of any importance. Its wild and fierce tribes were not subdued by any of the great empires of antiquity, and are only known to us by the incursions that they made into the more civilized countries to the south. The Romans frequently encountered them on the borders of Pannonia and Mœsia, and after the conquest of Dacia, also in that province. But they never inflicted any serious damage on the empire; and in later times, when the people of these countries came into historical prominence, the name of Sarmatians had disappeared, superseded by the better known appellation of Vandals and Huns. It is to be observed, that the people described by Herodotus under the name of Sauromatæ, which is merely a different form of Sarmatæ, did not occupy the whole of the country known in the time of Ptolemy as Sarmatia, but only that portion of it which lies between the Don, the Volga, and Mount Caucasus; the rest being inhabited by the Scythians. Whether or not the Sarmatians were a distinct people from the Scythians, is a somewhat doubtful point; but it is probable that the two were distinct, and that the former belonged to the Slavonic and Lithuanic, the latter to the Turkish races. See **SCYTHIA**. The Sarmatians wandered about in large waggons, surmounted by tents, and drawn by oxen, wherever their pastoral avocations, the pursuit of game, or their warlike passions, might direct their movements. A vivid description of these savage barbarians is given in the poetical epistles, which were written by Ovid from his place of banishment, near the mouth of the Danube; where he was exposed to the assaults, probably, of the Jazygæ, one of the fiercest and most powerful of these tribes.

SARNO, a town of Naples, in the province of Principato Citra, near the source of the Sarno, at the foot of the Apennines, 12 miles N.N.W. of Salerno. It has an old castle, a fine cathedral, with some good paintings, several

other churches and convents, and an hospital. About the middle of the town there are mineral springs, which are much resorted to. Paper-mills, iron, and copper foundries are the chief manufacturing establishments in the place. Silk is produced in abundance in the neighbourhood. Not far off are some remains of an ancient aqueduct. Pop. 12,000.

SAROS-PATAK, a town of Hungary, in the county, and 15 miles S.W. of Zemplin. It stands on the Bodrog, and contains a once famous but now ruined castle, a large protestant seminary, a Roman Catholic upper school, &c. Cloth is made here, and wine raised in the vicinity. Pop. (1846) 5480.

SARREGUEMINES, or **SAARGEMUND**, a town of France, capital of an arrondissement in the department of Moselle, at the confluence of the Saar and the Bêlise, 42 miles E. of Metz. The most notable buildings are the prison and a former convent, now divided between the court-house, the sub-prefect's residence, and the lecture-rooms of the college. The town has manufactures of leather, silk, earthenware, &c.; and is the centre of a considerable trade in snuff-boxes, which are made in large numbers in the vicinity. Pop. (1856) 4918.

SARSAPARILLA (*Smilax Sarsaparilla*), a plant growing in Russia, Central and South America, and the West Indies, the roots of which have long had celebrity in the cure of certain cutaneous diseases. The best mode of using it is in decoction, of which half-a-pint may be taken daily, or half-an-ounce of the powder. In 1857 there was imported into Britain of this plant 205,392 lbs., at a total cost of £11,184.

SARTHE, a department of France, bounded on the N. by that of Orne, E. by those of Eure-et-Loir and Loir-et-Cher, S. by those of Indre-et-Loire and Maine-et-Loire, and W. by that of Mayenne. Its length from N. to S. is about 62 miles; greatest breadth, 58; area, 2395 square miles. It is very compact, and nearly circular in form. The surface is almost unbroken, sloping very gradually from the north-west, where the highest elevations in the department occur. It belongs entirely to the valley of the Loire, and the principal river is that from which the department takes its name. It enters the country from the north, forms for some distance the north-western boundary, and then flows generally southwards through the centre of the department. Its principal affluents here join it from the left, the Orne, Huisne, and Loir watering the eastern portion of Sarthe. Of all these rivers only two, the Sarthe and the Loir, are navigable, the former up to Le Mans, and the latter to Chateau-du-Loir, giving a total length of 254 miles of river navigation within the department. Besides those mentioned, various smaller streams traverse the country; these, as well as the others, abounding in fish. The geological structure of the land exhibits a considerable variety; in the north-west, granite is the prevailing rock, as a portion of the department here belongs to the great primitive formation of Bretagne. As we proceed south-east, across the country, we come upon new red sandstone, and afterwards, in succession, the various formations between this and the chalk group; the extreme south-east of the department being entirely cretaceous. The mineral wealth of the country is very considerable. There are coal-pits in the western portion; iron is also obtained, as well as marble, slate, paving-stone, mill-stones, fuller's earth, potter's clay, &c. The department throughout is an agricultural country. Its plains and gentle slopes have a fertile soil, and are generally well cultivated; the waste land in the department is continually diminishing in extent. The quantity of corn produced is more than sufficient to supply the demand. Besides wheat, there is grown here, maize, buckwheat, potatoes, and pulse of various kinds; wine is produced, but of an inferior quality; fruit-trees are carefully

Saros-Pa-

tak

||

Sarthe.

Sarti.

cultivated; and much cider is made. Of the entire area of the department, about 804,150 acres are occupied by arable land; 145,000 by meadows; 25,000 by vineyards; 170,000 by wood; 112,500 by waste land. On the extensive and rich tracts of pasture land, both natural and artificial, large numbers of live stock are raised; the cattle are of good breed, the horses much esteemed for carriages; and a considerable amount of profit is derived from the sale of poultry. It is calculated that there are in the department 123,000 head of horned cattle, 122,000 sheep, 76,000 pigs, 20,000 goats, and 56,000 horses. Honey, chestnuts, dried and preserved fruit, form some of the articles of trade. There is not much manufacturing industry; cloth of various qualities is the principal article made; there are also bleach-works and manufactories of wax-candles. Some trade is carried on in the mineral and agricultural produce of the country. Internal communication is facilitated by the rivers, by numerous roads, and by four railways, diverging from Le Mans in different directions. The department forms, along with that of Mayenne, the diocese of Le Mans; it contains law courts, subordinate to the imperial court at Angers, 5 colleges, a normal school, 8 upper and 609 elementary schools. The capital is Le Mans; and the department is divided into four arrondissements, as follows:—

	Cantons.	Communes.	Pop. (1856.)
Le Mans.....	10	116	173,458
Mamers	10	143	125,758
Saint-Calais.....	6	56	66,850
La-Flèche	7	80	101,127
Total.....	33	395	467,193

SARTI, GIUSEPPE, an excellent Italian composer, was born at Faenza, in the Papal States, on 28th December 1729. He studied composition under Padre Martini, at Bologna, and in 1752 produced his first opera, *Il Re pastore*, which was performed at Faenza with the greatest success. Several other operas which he composed soon afterwards added to his high reputation. In 1756 he was called to Copenhagen as chapel-master and professor of singing to the hereditary prince. Several operas which he composed there were coldly received; and, in disgust, he resigned his employments and returned to Italy in 1765. His countrymen had half-forgotten him, and the operas which he composed for Rome, Venice, &c., had no great success. In 1769 he visited London, but could not get any of his operas performed there, and was obliged to give lessons in singing and on the harpsichord. He published, at London, six sonatas for the harpsichord, which are highly valued by professional musicians. Returning to Italy in 1770, he accepted the office of master of the Conservatory of the Ospedaleto, left vacant by Sacchini's visit to England. This was the beginning of Sarti's most brilliant career, from 1771 to 1784, during which he composed his best operas,—among these, *Le gelosie Villane*, *Giulio Sabino*, and *Le nozze di Dorina*. In 1779 he was appointed chapel-master of the Duomo at Milan, having proved his superiority over the many eminent competitors opposed to him. The hymn, psalm, and mass for six and eight real voices, which he wrote for that competition, afford evidence of his profound skill and learning. Between 1779 and 1784 he wrote a great deal of church music, besides operas. In July 1784 he was called to St Petersburg as director of court music, and was received with great favour by the Empress Catherine II. In a *Te Deum* which he composed at this time, he thought to add to the solemnity of effect by introducing cannon, to be fired at certain intervals. By the intrigues of the celebrated singer, Signora Todi, the empress was persuaded to dismiss Sarti, who then found a protector in Prince Potemkin, and employment as master of a singing school in the Ukraine, in a village presented to him by the prince. After the death of Potemkin, Sarti found means to regain the favour of the empress, who not only restored

Sarto.

to him his former appointments, but fixed his salary at 35,000 roubles, with apartments in the palace. By her orders he formed a conservatory of music; and when the pupils gave their first concert in 1795, the empress was so much pleased that she raised Sarti to the highest rank of nobility, and bestowed a considerable territory upon him. His strength failing, he attempted to return to Italy in 1802, but was unable to proceed further than Berlin, where he died, on 28th July, aged 73. The most distinguished of Sarti's pupils was the celebrated Cherubini, who, in his work on Counterpoint and Fugue (French edit., pp. 188–195), gives, as a model, a Real Fugue, in eight parts, for two choirs, by Sarti.

Sarti was one of the most learned and skilful composers of the last century. He had the rare gift of inventing beautiful and appropriate melodies. William Shield, in his *Introduction to Harmony*, pp. 92–94, gave a charming vocal Terzetto by Sarti. Sarti's dramatic compositions amounted to forty-two; and his compositions for the church were numerous, including a *Miserere*, four *Masses*, and the *Te Deum* before mentioned. He constructed an apparatus for counting the number of vibrations made by any given sound in a second of time. Sauveur had experimented on that subject in the latter part of the seventeenth century. Sarti wrote a severe criticism upon the harmony of two passages in the introductory movement to Mozart's Quartet in C, and in the first movement of that in D minor, for two violins, viola, and violoncello. Certainly the effect of those passages is highly unsatisfactory. (G. F. G.)

SARTO, ANDREA D'AGNOLO VANNUCCHIO, called DEL, from his father's occupation of a tailor, was born in Florence in 1488. At the early age of seven years he was placed with a goldsmith, but he showed a much greater liking for the pencil than the burin at that early age. A painter named Barile, more noted for his generosity than for his knowledge of the art, took the young Sarto to instruct him in painting. The lad made great progress, and was soon transferred to the school of Pietro Cosimo, then considered one of the best painters in Italy. Sarto continued to make very steady progress; and formed an intimacy with Francio Bigio, with whom he executed numerous paintings for the public buildings of Florence. He painted a fine fresco for the ducal palace at Poggio a Caiano, and an excellent "Pietà" for the nuns of Lugo. On his return from Rome, whither he had lately gone, he painted a "Holy Family in Repose," a work of great merit; and executed his "Descent of the Holy Ghost," the "Birth of the Virgin," and "Last Supper," for the monastery of Salvi. The story told by Lanzi, of the soldiers being astounded by the latter painting at the siege of Florence in 1529, need not be repeated in the artist's favour. A band of wild soldiers, bent on plunder, could scarcely be expected to have either the patience or taste necessary for estimating such a sublime work of art. Yet painting, probably, like the music which Orpheus drew from his lyre, has charms capable of fascinating alike the wild savage and the lettered Roman. Sarto was afterwards engaged on a "Dead Christ" for Francis I., King of France, when that monarch gave him a most regal invitation to his court. Andrea went to Paris, and was feasted and robed in great magnificence, when suddenly, on the receipt of a letter from his wife, a woman who possessed the single merit of great personal attractions, he immediately left for Florence, with the intention of procuring pictures for the king, by whom he was entrusted with a considerable sum for that purpose. Notwithstanding his solemn pledge to return again to Paris, the artist spent his time and squandered away the king's money. Sunk in poverty and despondency, filled with public and domestic wretchedness, abandoned by his wife and all his former associates, he died of the plague in 1530, in his forty-second year. Bryan makes his death occur much

Sarum
||
Sassari.

later. Thus ended the career of one who was, in the words of his pupil Vasari, "the most faultless painter of the Florentines, for perfectly understanding the principles of chiaroscuro, for representing the indistinctness of objects in shadow, and for painting with a sweetness truly natural."

SARUM, OLD, was formerly a parliamentary borough of England, in Wiltshire, 2 miles N. of Salisbury; returning two members to parliament, though without a single house or inhabitant. It was thus, before the Reform Act of 1832, by which it was disfranchised, the most complete instance of a rotten borough. The place is, however, of great antiquity, having existed, under the name of Sorbiodunum, in the time of the Romans. It was fortified by Alfred, and after the Norman Conquest was made the seat of a bishop. The cathedral was removed in 1220, in consequence of a quarrel between the bishop and the people, to Salisbury, or New Sarum; and from that time Old Sarum began to decline. Some remains of walls and ditches still exist.

SARUN, a district of British India, under the lieutenant-governor of Bengal, lying between N. Lat. 25. 40. and 27. 29., E. Long. 83. 55. and 85. 30.; bounded on the N. by the kingdom of Nepal, E. by the district of Tirhoot, S. by those of Patna, Shahabad, and Ghazecpoor, and W. by that of Goruckpoor. Length about 115 miles from north to south; breadth, 90; area, 6394 square miles. It is almost entirely even, with no mountains or hills; and has a general slope towards the south-east, in which direction the most of the rivers flow. The southern border of the district is washed by the Ganges, between the points where it receives the Ghaghra and the Gunduk; the former of which forms the south-western, and the latter the eastern, boundary of Sarun. The Ganges and the Ghaghra are both navigable here. Of the numerous other rivers the most important is the Bagmuttee. The soil is exceedingly fertile, and produces wheat, barley, rice, maize, millet, and pulse of various kinds, besides opium, tobacco, indigo, cotton, &c. There are, especially in the north of the district, large and valuable forests of saul and other timber. The manufactures are few and unimportant; and the trade consists chiefly in the exportation of raw produce, and the importation of silk, broadcloth, salt, &c. Sarun once belonged to the powerful kingdom of Magadha; and subsequently formed part of the province of Behar, which was granted to the East India Company in 1765 by the Mogul. Pop. 1,700,000.

SARZEAU, a town of France in the department of Morbihan, on the peninsula of Ruis, which forms the south shore of the bay of Morbihan, 14 miles S. of Vannes. The principal building is a church with a lofty tower; and another object, so conspicuous as to form a sea-mark for coasting vessels, is a high conical *tumulus*, the largest in France. The town is chiefly inhabited by sailors, and has some trade in salt and in the indifferent wine of the vicinity. Sarzeau was the birthplace of Le Sage, the well-known author of *Gil Blas*. Pop. 7425.

SASSARI, a town of Sardinia, capital of the division of the same name, forming the northern part of the island, stands on a hill near the Turritano, about 9 miles above its mouth at Porto Torres, and 105 N.N.W. of Cagliari. Around it lies a rich and beautiful tract of gardens, orchards, vineyards, and well cultivated fields. The town is encircled by walls, outside of which are shady promenades; and the houses, especially in the main street, are substantial and handsome. Among its twenty-five churches, the most remarkable are the large massive cathedral and a fine Minorite church. There are, too, a castle; numerous convents; a university, founded in 1766, and attended in 1842 by 240 students; two colleges; an ecclesiastical seminary; three palaces, that of the governor, of the archbishop, and of the Duke of Asinara; a small public library; and a fine theatre.

Sassaram
||
Sattara.

Sassari is the seat of several courts of law and public offices. The only important manufacture is that of tobacco, for which there is here the largest establishment in the island. The trade, carried on through Porto Torres, consists chiefly in the exportation of articles of domestic produce; grain, oil, cheese, and skins. The ancient town, Tunis Libysonis, which occupied the site of Porto Torres, was one of the most important in the island; but about the eleventh century A.D. the whole population migrated inland to Sassari, which from that period began to rise into importance. Some remains of antiquity are still to be seen at Porto Torres. Pop. 23,000.

SASSERAM, a town of British India, in the district of Shahabad, 72 miles S.E. of Benares, and 117 N.W. of Hazareebagh. It is extensive, but chiefly occupied by ruined Mohammedan mosques and tombs. There is a bazaar; and a few manufactures of hardware and jewellery are carried on. Pop. estimated at 10,000.

SATALIAH, or ADALIA, a town of Asiatic Turkey, at the head of the bay of the same name, on the Mediterranean, 50 miles N.E. of Cape Khelidonia. It occupies a fine position, on a cliff rising steeply from the sea to the height of 70 or 80 feet, and encircled on the landward side by vineyards and orchards. The houses rise one above the other up the hill; and the view from the more lofty points of the bay and the mountains that skirt its shores is exceedingly beautiful. On the summit of the hill stands a castle; and in other parts of the town there are churches, mosques, baths, caravanserais, and many ancient remains. The port, which is formed by two moles, is of considerable size, but now only frequented by a few small vessels. Pop. 8000.

SATORALYA-UJHELY, or simply UJHELY, a market-town of Hungary, capital of the county of Zemplin, on the Hegyalja Hills, which are celebrated for their wines, 46 miles S.S.E. of Eperies, and 138 N.E. of Pesth. It contains several churches, belonging to various religious bodies, a Pianist college, and a gymnasium. Pop. 7200.

SATTARA, a province of British India, in the presidency of Bombay, lying between N. Lat. 16. 22. and 18. 32., E. Long. 73. 24. and 76. 25.; bounded on the N. by the collectorate of Poona, N.E. and E. by that of Sholapoor, S. by that of Belgaum, the southern Mahratta jaghires, and the native state of Colapoor, and W. by the collectorates of Ratnagerry and Tannah. Length from N.W. to S.E. about 215 miles, breadth about 90; area 11,000 square miles. The western frontier of the province is skirted by the Siadri Mountains, or Western Ghats, which separate it from the Concan; and though very precipitous on the W. side, have a more gradual slope within the limits of Sattara, sinking towards the plains of Hyderabad to the S.E. The surface is, however, for the most part rugged, and broken by high ridges and isolated hills, and the soil is in general barren. All the rivers follow in their course the general declivity of the country, and discharge their waters finally into the Kistna, which has its source and the upper part of its course within the province. Besides this, Sattara is watered by the Neera, and other rivers of smaller size. In the loftier districts of the country the climate is extremely moist; and in some parts of the Ghats the annual fall of rain is sometimes nearly as much as 300 inches. In these districts the heat is alleviated by the great elevation of the country, and the mean annual temperature is about 66°. The lower parts of the province have a much greater degree of heat, and suffer greatly from want of rain; for sometimes not more than 23½ inches fall during the whole year. Sattara, however, enjoys a healthy climate; and, considering the mountainous and barren nature of the country, the population is pretty dense, being in the ratio of about 100 per square mile. The great majority of the people belong to the Mahratta race, which has had from the most remote antiquity its head-quarters in

Sattara
||
Saturnus.

this part of India. From the period of the rise of their power under Sevajee, onwards until it had begun to decline, Sattara formed part of the Mahratta empire; and in 1818, when the rajah was delivered by the British from the durance in which he had been held by his peishwa or prime minister, the territory was assigned to him, along with several jaghires or feudal grants. The administration of the government was carried on for four years by a British agent, but after that time by the rajah himself. Disputes, however, arose between him and the Bombay government, which ended in his deposition and the elevation of his brother in 1839. This rajah died in 1848, leaving no issue; and as the line of Sevajee thus became extinct, the territory lapsed to the East India Company. During the reign of the last rajah a good road had been constructed from Sattara to Mahabulishwar, and another to complete the communication between Sattara and Poona. Since the accession of the British to power, these improvements have been diligently carried forward by the addition of several other roads throughout the country. The net revenue of the province for 1855-56 was L.132,587. Pop. 1,319,673.

SATTARA, the capital of the above province, in a valley between two ranges of hills on the E. and W., 55 miles S. of Poona, and 115 S.E. of Bombay. It has a strong fort, erected on the summit of a hill, about 1100 yards long by 500 across, and 800 feet in height. It is defended by the steepness of the rock, which at the N.E. corner has quite the appearance of a tower, having a perpendicular scarp of 42 feet, above which is a wall with an additional height of 25 feet. In 1700 this fort offered a vigorous resistance for two months to Aurungzebe, who besieged it in person, but it was reduced by blockade; and in 1818 a few bombshells procured its surrender to the British. The fort contains the old palace and numerous temples. It commands a fine view over the numerous hills of the surrounding country, many of them crowned with picturesque old forts. There is another palace in the town, a large but not very handsome edifice. In it is preserved, among other relics, the sword of Sevajee, a long, straight blade of fine polished steel.

SATURDAY, the seventh and last day of the week, so called from the idol Seater, worshipped on this day by the ancient Saxons, and thought to be the same as the Saturn of the Latins.

SATURN. See ASTRONOMY.

SATURNUS, a fabulous king or god of Italy, to whom was ascribed the introduction of agriculture and the arts of civilized life. Saturn, like the Greek Kronos, was regarded by the Romans as their most ancient deity; but here the identity of the two fabled gods ceases, as there was no resemblance, even such as the ancients alleged, between their several attributes. The name is said to be derived from *sero*, *sevi*, *satum*, to sow; and the deity is supposed to preside over everything which promotes the growth of vegetation. To his reign is ascribed the golden age of Italy, which disappeared with his disappearance. The country received his name, and was denominated Saturnia, or the land of plenty. He is reported to have come to Italy with his wife Ops, in the reign of Janus, and to have formed a settlement on the Capitoline hill. Like other mythical dignitaries, he suddenly disappeared from the eyes of man, and withdrew into godlike seclusion; whence, according to some, the name of Latium, from *lateo*, *I lie hid*. Janus is said to have erected an altar to his honour in the Roman forum; and the rustic population, in the month of December, instituted at Rome the festival of the *Saturnalia*, to celebrate in unrestrained merriment the memory of the founder of their peculiar industry, and the author of the golden age among men. The statue of the god was hollow and filled with oil, in his hand was placed a crooked pruning knife, and his feet were surrounded with a riband of wool.

VOL. XIX.

Satyrs
||
Saugor.

He is sometimes represented, also, as an old man with a scythe, a sand-glass, and wings; and occasionally as a serpent, with its tail in its mouth. This is supposed to shadow forth the seasons in their perpetual succession, and is most probably borrowed from the emblematical representations of the Greek god Kronos.

SATYRS. See BACCHUS.

SAUGOR and NERBUDDA TERRITORIES; an extensive tract of India, forming the S.W. portion of the presidency of Bengal, lying between N. Lat. 21. 16. and 23. 15., E. Long. 76. 53. and 82. 51.; bounded on the N. by Bundelcund and the British districts of Banda, Allahabad, and Mirzapore; E. by Mirzapore and the native state of Korea; S. by the dominions of the Rajah of Berar, and of the Nizam; and W. by those of the Rajah of Bhopal and of the Scindia family. Length from E. to W. 380 miles, breadth 190, area 27,632 square miles. The greater part of these extensive territories is governed directly by the British; but there are also comprised within their limits the independent allied state of Rewah, and the petty states of Kotee, Myhir, Docheyra, and Sohawul; feudatory to the British government. The territories are subdivided as follows:—

British Districts.	Area in Sq. Miles.	Pop. (1855)
Saugor	1857	305,594
Jubbulpore.....	6237	442,771
Hoshungabad	1916	242,641
Seonee	1459	227,070
Dumoh	2428	363,584
Nursingpore	501	254,486
Baitool	990	93,441
Total of British districts ..	15,388	1,929,587
Native states.....	12,244	1,560,000
Total	27,632	3,489,587

The country is elevated and mountainous. Its eastern portion is occupied by a tableland, which rises in the summit of Amarakantak, at the extreme S.E., to the height of 3463 feet above the sea, but gradually slopes westwards to the valley of the Nerbudda, which flows through the middle of the territories from E. to W. This valley is inclosed on the N. by the Vindhya range, which is not very high, few summits exceeding the height of 2000 feet; and on the S. by the Mahadeo mountains, which have an average height of 2000 feet, and in some places are believed to attain to 2500 feet, or even higher. These ranges separate the waters of the Nerbudda from the affluents of the Ganges and Jumna on the one side, as well as from those of the Godavery on the other. Among the mineral productions of the land, iron and coal are the most important, and they are found in great abundance in various places. Good sandstone and limestone are also quarried in different parts of the territories. As to the soil, it is in the greater part of Saugor and Nerbudda productive of cotton; but some portions of the surface are covered with dense and gloomy forests, occupied by savage Indians of the Ghond tribes. There are few important events connected with the history of these territories. Ruled originally by Ghond princes, they were conquered by Akbar about 1599, and thus annexed to the empire of Delhi. On the fall of that empire, the peishwa obtained a nominal supremacy over these lands; but they were afterwards conquered by the Rajah of Berar, and finally ceded to the British in 1818.

SAUGOR, the capital of the British district of the same name, in a hilly region, 185 miles N. of Nagpore, 223 S.W. of Allahabad, and 500 N.E. of Bombay. It is built on three sides of a small lake, lying in a valley near the river Bessi or Bes, which is crossed by a fine suspension bridge 200 feet in span. The military cantonments are extensive, but occupy a low, swampy, and unhealthy situation. There is a large fort, used as an ordnance dépôt; and the mint,

Saul
||
Saumarez.

which formerly occupied a very handsome building, has been removed to Calcutta. Saugor has a Gothic church, recently erected; and a collegiate school, where both English and the vernacular languages are taught. It is the seat of the civil establishment, and has several hundred European inhabitants. The whole population, chiefly Mah-rattas, is estimated at 50,000.

SAUL, the son of Kish, of the tribe of Benjamin, was the first king of the Israelites; and, on account of his disobedient conduct, the kingdom was taken from his family and given to David.

SAUMAREZ, JAMES, BARON DE, *Admiral*, was born at St Peter Port, in the island of Guernsey, on the 11th of March 1757. He was descended from an old family which had originally come from France, and which had held a prominent place for centuries among the gentry of the Channel Islands. The family name, originally Sausmarez, was changed about 1700 to Saumarez. Not a few of his kin had already distinguished themselves in the naval service, and this circumstance probably fired the lad's ambition early to run the career peculiar to his house. At the age of thirteen, he accordingly entered the navy as midshipman, and served successively in the Montreal, Winchester, and Levant frigates. He distinguished himself at the attack on Charleston, in America, in 1775, on board the Bristol, for which he was raised to the rank of lieutenant. He rose successively under Lord Cornwallis, and Admiral Sir Hyde Parker, until he was promoted to the rank of commander for his gallant services off the Dogger Bank, on the 5th of August 1781. Captain Saumarez now placed himself under Admiral Kempenfeldt, and he subsequently, while commanding the Russell, a ship of the line, gained great distinction by his conduct at the battle of the 12th of August 1782. A lull of peace succeeded, and for the next ten years he enjoyed the society of his friends in the Channel Isles. On the breaking out of the war with France in January 1793, Saumarez captured La Reunion, a French frigate, for which he received the honour of knighthood. In the month of November following, Sir James received the command of a small squadron, which, on the 5th of June 1794, was attacked by a very superior French force on the way from Plymouth to Guernsey. But so great was the commander's knowledge of the soundings of the Guernsey coast, and so cool was his intrepidity, that he succeeded in gaining a safe anchorage in the harbour of that island, to the great chagrin of the French fleet.

Sir James Saumarez was promoted in 1795 to the Orion, of 74 guns, and engaged in a series of memorable victories under Lord Bridport, Sir John Jervis, and Sir Horatio Nelson. On his return from the battle of the Nile, where he was severely wounded, he received the command of the *Cæsar*, 84 guns, with orders to watch the French fleet in Brest, during the winters of 1799 and 1800. In 1801 he was raised to the rank of rear-admiral of the blue, was created a baronet, and received the command of a small squadron which was destined to watch the movements of the Spanish fleet at Cadiz. In the month of July, Admiral Saumarez had the satisfaction of preserving a fleet of British merchantmen from falling into the hands of the French. To effect this object he had to engage in two sharp contests with the French and Spanish fleets off Algeziras, which caused the enemy a loss of 3000 men in blown up, killed, and taken prisoners. This Saumarez effected with a small squadron, not half equal in size to the enemy's fleet. Of this contest Lord Nelson remarked that "a greater action was never fought." The admiral was rewarded by the Order of the Bath, and the freedom of the city of London was voted to him, together with a magnificent sword. In 1803 Sir James received a pension of £1200 a year, and on the breaking out of hostilities with

Saumur
||
Saunderson

Russia, he was intrusted with the command of the Baltic fleet, where he had to bring into play all his diplomatic talent. Charles XIII. of Sweden bestowed upon him the Grand Cross of the Military Order of the Sword, as an expression of gratitude for his services. At the peace of 1814 he was made full admiral, in 1819 rear-admiral, and in 1821 vice-admiral of Great Britain. He struck his flag for the last time on the 10th of May 1827. He was raised to the peerage as Baron de Saumarez in 1831. The remainder of his life was spent in peaceful retirement on his estate at Guernsey, where he died on the 9th of October 1836. (See *Memoirs, &c., of Admiral Lord de Saumarez*, by Sir John Ross, 2 vols., 1838.)

SAUMUR, a town of France, capital of an arrondissement in the department of Maine-et-Loire, on the left bank of the Loire, 25 miles S.S.E. of Angers. It is a picturesque, cheerful, white town, occupying the side and foot of a hill by the river's side. The upper portion, called the high town, is very irregular, overhung by the old castle, with its tall donjon and terraced bastions, looking out on the rich flat country through which the Loire flows. The low town is more imposing in its architecture, and contains a good quay, and a quaint old town-hall, with high sloping roof and embattled walls. On the other side of the river stands a suburb, to which access is gained by a very fine stone bridge of twelve arches. The streets of Saumur are in general crooked, and many of them steep. Besides those already mentioned, the principal buildings are two churches, that of St Pierre, in the pointed style, but disfigured by a modern Italian front; and that of Notre Dame de Nantilly, which has some portions as old as the eleventh century, and is hung with curious antique tapestry from the Flemish looms. There are here a public library, museum, theatre, baths, courts of law, a college, riding-school, &c. Linen, cambric, glass, enamelled articles, leather, and salt-petre, are produced here; and there is some trade in corn, flour, wine, hemp, &c. During the reign of Henri IV., Saumur was a flourishing town of 25,000 inhabitants, and a stronghold of the Protestant interest; but after the revocation of the Edict of Nantes, its population dwindled to one-fourth of its previous amount, by the loss of its most industrious inhabitants. During the revolutionary war, it was the scene of one of the most brilliant exploits of the Vendéans, under Larochejacquelin. With a very small force he stormed the heights, which were defended by a republican army of 15,000 men with 100 guns, and afterwards drove the enemy from the town, and compelled the castle to surrender. This took place in June 1793. Pop. (1856) 13,073.

SAUNDERSON, DR NICHOLAS, was born at Thurlstone, in Yorkshire, in 1682, and may be considered as a prodigy for his application and success in mathematical literature, in circumstances apparently the most unfavourable. He lost his sight by the small-pox before he was a year old. But this disaster did not prevent him from searching after that knowledge for which nature had given him so ardent a desire. He was initiated into the Greek and Roman authors at a free school at Penniston. After spending some years in the study of the languages, his father, who had a place in the excise, began to teach him the common rules of arithmetic. But he soon surpassed his father, and could make long and difficult calculations without having any sensible marks to assist his memory. At eighteen he was taught the principles of algebra and of geometry by Mr Richard West of Underbank, who, though a gentleman of fortune, yet, being strongly attached to mathematical learning, readily undertook the education of so uncommon a genius. Saunderson was also assisted in his mathematical studies by Dr Nettleton. These two gentlemen read books to him, and explained them. He was next sent to a private academy at Attercliff, near Shef-

Saunderson field, where logic and metaphysics were chiefly taught. But these sciences not suiting his turn of mind, he soon left the academy. He lived for some time in the country without any instructor; but such was the vigour of his own mind, that few instructions were necessary. He only required books and a reader.

His father, besides the place he had in the excise, possessed also a small estate; but having a numerous family to support, he was unable to give him a liberal education at one of the universities. Some of his friends, who had remarked his perspicuous and interesting manner of communicating his ideas, proposed that he should attend the university of Cambridge as a teacher of mathematics. This proposal was immediately put in execution, and he was accordingly conducted to Cambridge in his twenty-fifth year by Mr Joshua Dunn, a fellow-commoner of Christ's College. Though he was not received as a member of the college, he was treated with great attention and respect. He was allowed a chamber, and had free access to the library. Whiston was at that time professor of mathematics, and as he read lectures in the way that Saunderson intended, it was naturally to be supposed he would view his project as an invasion of his office. But, instead of meditating any opposition, the plan was no sooner mentioned to him than he gave his consent to it. Saunderson's reputation was soon spread throughout the university. When his lectures were announced, a general curiosity was excited to hear such intricate mathematical subjects explained by a man who had been blind from his infancy. The subject of his lectures was the *Principia Mathematica*, the Optics, and the *Arithmetica Universalis*, of Sir Isaac Newton. He was accordingly attended by a very numerous audience. It will appear at first incredible to many that a blind man should be capable of explaining optics, which requires an accurate knowledge of the nature of light and colours; but we must recollect that the theory of vision is taught entirely by lines, and is subject to the rules of geometry.

While thus employed in explaining the principles of the Newtonian philosophy, he became known to its illustrious author. He was also intimately acquainted with Halley, Cotes, Demoivre, and other eminent mathematicians. When Whiston was removed from his professorship, Saunderson was universally allowed to be the man best qualified to succeed him. But to enjoy this office it was necessary, as the statutes direct, that he should be promoted to a degree. To obtain this privilege, the heads of the university applied to their chancellor, the Duke of Somerset, who procured the royal mandate to confer upon him the degree of master of arts. He was then elected Lucasian professor of mathematics in November 1711. His inauguration speech was composed in classical Latin, and in the style of Cicero, with whose works he had been much conversant. He now devoted his whole time to his lectures and the instruction of his pupils. In 1728, when George II. visited the university of Cambridge, he expressed a desire to see Professor Saunderson. In compliance with this desire, he waited upon his majesty in the senate-house, and was there, by the king's command, created doctor of laws. He was admitted a member of the Royal Society in 1736.

Saunderson was naturally of a vigorous constitution, but having confined himself to a sedentary life, he at length became scorbutic. For several years he felt a numbness in his limbs, which, in the spring of 1739, brought on a mortification in his foot; and, unfortunately, his blood was so vitiated by the scurvy, that assistance from medicine was not to be expected. When he was informed that his death was near, he remained for a little space calm and silent; but he soon recovered his former vivacity, and conversed with his usual ease. He died on the 19th of April 1739, in the fifty-seventh year of his age, and was buried, at his own request, in the chancel at Boxworth. He mar-

ried the daughter of Mr Dickens, rector of Boxworth, in Cambridgeshire, and by her had a son and a daughter.

Dr Saunderson was rather to be admired as a man of wonderful genius and assiduity, than to be loved for his amiable qualities. He spoke his sentiments freely of characters, and praised or condemned his friends as well as his enemies without reserve. This has been ascribed by some to a love of defamation; but it has with more propriety been attributed by others to an inflexible love of truth, which urged him upon all occasions to speak the sentiments of his mind without disguise, and without considering whether this conduct would please, or the reverse. His sentiments were supposed to be unfavourable to revealed religion. It is said that he alleged he could not know God, because he was blind, and could not see his works; and that upon this Dr Holmes replied, "Lay your hand upon yourself, and the organization which you will feel in your own body will dissipate so gross an error." On the other hand, we are informed that he had desired the sacrament to be given him on the evening before his death. He was, however, seized with a delirium, which rendered this impossible.

He wrote a system of algebra, which was published in two volumes 4to, at London, after his death, in the year 1740, at the expense of the university of Cambridge.

Dr Saunderson had invented for his own use a palpable Arithmetic; that is, a method of performing operations in arithmetic solely by the sense of touch. It consisted of a table raised upon a small frame, so that he could apply his hands with equal ease above and below. On this table were drawn a great number of parallel lines, which were crossed by others at right angles; the edges of the table were divided by notches half an inch distant from one another, and between each notch there were five parallels, so that every square inch was divided into a hundred little squares. At each angle of the squares where the parallels intersected one another, a hole was made quite through the table; and in each hole were placed two pins, a large and a small one. It was by the various arrangements of the pins that Saunderson performed his operations.

His sense of touch was so perfect, that he could discover with the greatest exactness the slightest inequality of surface, and could distinguish in the most finished works the smallest oversight in the polish. In the cabinet of medals at Cambridge he could single out the Roman medals with the utmost correctness; and he could also perceive the slightest variation in the atmosphere. One day, while some gentlemen were making observations on the sun, he took notice of every little cloud that passed over his disk, and served to interrupt their labours. When any object passed before his face, even though at some distance, he discovered it, and could guess its size with considerable accuracy. When he walked, he knew when he passed by a tree, a wall, or a house. He had made these distinctions from the different ways his face was affected by the motion of the air.

His musical ear was so remarkably acute, that he could distinguish accurately to the fifth of a note. In his youth he had been a performer on the flute, and he had made such proficiency, that if he had cultivated his talents in this way, he would probably have been as eminent in music as he was in mathematics. He recognized not only his friends, but even those with whom he was slightly acquainted, by the tone of their voice; and he could judge with wonderful exactness of the size of any apartment into which he was casually conducted.

SAURAT, a village of France, in the department of Ariège, 7 miles S.S.W. of Foix. It has an old church, iron-works, saw-mills, and slate-quarries. Pop. 4466.

SAURIN, JACQUES, a celebrated preacher, was the son of a Protestant lawyer, and was born at Nismes in 1677.

Saurat
||
Saurin.

Saurin.

He applied to his studies with great success; but being captivated with a military life, he relinquished them for the profession of arms. In 1694 he made a campaign as a cadet in Lord Galloway's company, and soon afterwards obtained a pair of colours in the regiment of Colonel Renault, which served in Piedmont. But the Duke of Savoy having made peace with France, he returned to Geneva, and resumed the study of philosophy and theology under Turretin and other professors. In 1700 he visited Holland, then went to England, where he remained for several years, and married. In 1705 he returned to the Hague, where he fixed his residence, and preached with the most unbounded applause. To an exterior appearance highly prepossessing, he added a strong and harmonious voice. The sublime prayer which he recited before his sermon was uttered in a manner highly affecting. Nor was the attention excited by the prayer, dissipated by the sermon. All who heard it were charmed; and those who came with an intention to criticise, were carried along with the preacher and forgot their design. Saurin had, however, one fault in his delivery; he did not manage his voice with sufficient skill. He exhausted himself so much in his prayer and the beginning of his sermon, that his voice grew feeble towards the end of the service. His sermons, especially those which were published during his life, are distinguished for justness of thought, force of reasoning, and an eloquent, unaffected style. Saurin died on the 30th of December 1730, aged fifty-three years.

He wrote, first, *Sermons*, which were published in 12 vols. 8vo and 12mo, some of which display great genius and eloquence, and others are composed with negligence. One may observe in them the imprecations and the aversion which the Calvinists of that age were wont to utter against the Roman Catholics. Saurin was, notwithstanding, a lover of toleration; and his sentiments on this subject gave great offence to some of his fanatical brethren, who attempted to obscure his merit and embitter his life. They found fault with him because he did not call the pope Antichrist, and the Church of Rome the whore of Babylon.

Secondly, he published *Discours*, historical, critical, and moral, on the most memorable events of the Old and New Testament. This is his greatest and most valuable work. It was first printed in 2 vols. folio. As it was left unfinished, Beausobre and Roques undertook a continuation of it, and increased it to four volumes. He also published *L'Etat du Christianisme en France*, 1725, 8vo, in which he discusses many important points of controversy, and calls in question the truth of the miracle said to have been performed on La Fosse at Paris; and an *Abrégé* of Christian theology and morality, in the form of a catechism, 1722, 8vo.

A *Dissertation* which he published on the *Expediency of sometimes Disguising the Truth* raised a multitude of enemies against him. He was immediately attacked by several adversaries, and a long controversy ensued; but his doctrines and opinions were at length publicly approved of by the synods of Cambray and the Hague. This work was translated into English by Chamberlayne, London, 1723. Five volumes of his *Sermons* were likewise translated by R. Robinson, 1775.

SAURIN, Joseph, a geometrician and member of the Academy of Sciences at Paris, was born at Courtaison, in the principality of Orange, in the year 1659. His father, who was a minister at Grenoble, was his first preceptor. He made rapid progress in his studies, and, when very young, was admitted minister of Eure in Dauphiné; but having made use of some violent expressions in one of his sermons, he was obliged to quit France in the year 1683. He retired to Geneva, and thence to Berne, where he obtained a considerable living. Scarcely was he settled in his new habitation, however, when some theologians raised a persecution

Saussure.

against him. Saurin, hating controversy, and disgusted with Switzerland, where his talents were entirely concealed, repaired to Holland. He returned soon afterwards to France, and surrendered himself into the hands of Bossuet, the bishop of Meaux, who obliged him to make a recantation of his errors. This event took place in 1690. His enemies, however, suspected his sincerity in the abjuration which he had made. It was a general opinion, that the desire of cultivating science in the capital of France had a greater effect in producing this change than religion. Saurin, however, speaks of the Reformers with great asperity, and condemns them for going too far. It is said, also, that Saurin appeased his conscience by reading Poiret's *Cogitationes Rationales*. This book is written with a view to vindicate the Church of Rome from the charge of idolatry. If it was the love of distinction that induced Saurin to return to the Church of Rome, he was not disappointed; for he there met with protection and support. He was favourably received by Louis XIV., obtained a pension from him, and was treated by the Academy of Sciences with the most flattering respect. At that time (1717) geometry formed his principal occupation. He enriched the *Journal des Savans* with many excellent treatises; and he added to the memoirs of the academy many interesting papers. These are the only works which he has left behind him. He died at Paris, of a fever, on the 29th of December 1737, in his seventy-eighth year. He married a wife of the family of Crousas, in Switzerland, who bore him a son, Bernard Joseph, distinguished as a writer for the theatre.

Saurin was of a bold and impetuous spirit. He had that lofty deportment which is generally mistaken for pride. His philosophy was austere; his opinions of men were not very favourable; and he often delivered them in their presence. This created him many enemies. His memory was attacked after his decease. A letter was printed in the *Mercure Suisse*, said to be written by Saurin from Paris, in which he acknowledges that he had committed several crimes which deserved death. Some Calvinist ministers published, in 1757, two or three pamphlets to prove the authenticity of that letter; but Voltaire, in his *Histoire Générale*, made diligent inquiry, not only at the place where Saurin had been discharging the sacerdotal office, but at the deans of the clergy of that department. They all exclaimed against an imputation so opprobrious. It must not, however, be concealed, that Voltaire, in the defence which he has published in his general history of Saurin's conduct, leaves some unfavourable impressions upon the reader's mind. He insinuated that Saurin sacrificed his religion to his interest, and that he played upon Bossuet, "who believed he had converted a clergyman, when he had only given a little fortune to a philosopher."

SAUSSURE, HORACE BÉNÉDICT DE, a celebrated naturalist, was a native of Geneva, and born in the year 1740. His father was an intelligent farmer, who lived at Conches, about half a league from Geneva, and the youth seems early to have taken to the study of natural history. Botany, which was his favourite study, was the means of introducing him to the acquaintance of the great Haller, to whom he paid a visit in 1764, and who was astonished at his intimate acquaintance with every branch of the natural sciences. His attachment to the study of the vegetable kingdom was also increased by his connection with Charles Bonnet, who had married his aunt, and who put a proper estimate on the talents of his nephew. He was at that time engaged in the examination of the leaves of plants, to which Saussure was also induced to turn his attention, and published the result of his researches, under the title of *Observations sur l'écorce des Feuilles et des Pétales*, in 1762. About this time the philosophical chair at Geneva became vacant, and was given to Saussure, at the age of twenty-

Sauveur. one. During the first fifteen years of his professorship he was alternately engaged in discharging the duties of his office and in traversing the mountains in the vicinity of Geneva; and in this period his talents as a great philosopher were fully displayed. He extended his researches on one side to the banks of the Rhine, and on the other to the country of Piedmont. He travelled to Auvergne to examine the extinguished volcanoes, going afterwards to Paris, England, Holland, Italy, and Sicily. The first volume of his travels through the Alps, which was published in 1779, contains a circumstantial description of the environs of Geneva, and an excursion as far as Chamouni, a village at the foot of Mont Blanc. It contains a description of his *magnetometer*. In proportion as he examined the mountains, the more was he persuaded of the importance of mineralogy; and that he might study it with advantage, he acquired a knowledge of the German language.

During the troubles which agitated Geneva in 1782, he made his beautiful and interesting experiments on *Hygrometry*, which he published in 1783. This has been pronounced the best work that ever came from his pen, and completely established his reputation as a philosopher. De Saussure resigned his chair to his pupil and fellow-labourer, Pictet, who discharged the duties of his office with reputation. In 1786, he published his second volume of travels, containing a description of the Alps around Mont Blanc, the whole having been examined with the eye of a mineralogist, geologist, and philosopher. It contains some valuable experiments on electricity, and a description of his own electrometer. To him we are indebted for the *cyanometer*, for measuring the degree of blueness of the heavens, which is found to vary according to the height of the observer; his *diaphanometer*, for measuring the transparency of the atmosphere; and his *anemometer*, for ascertaining the force of the winds. He founded the Society of Arts, to the operations of which Geneva is very much indebted for its continued prosperity. Over that society he presided to the day of his death, and the preservation of it in prosperity constituted one of his fondest wishes.

In 1794, the health of this eminent man began rapidly to decline, and a severe stroke of the palsy almost deprived him of the use of his limbs. His intellect still preserved its original activity, and he prepared for the press the last two volumes of his travels, which appeared in 1796, under the title of *Voyages dans les Alpes*. They contain a great mass of new facts and observations, of the last importance to physical science. He was in general a Neptunian, ascribing the revolutions of the globe to water, and admitting the possibility of mountains having been thrown up by elastic fluids disengaged from the cavities of the earth. In the midst of his rapid decline he cherished the hopes of recovery; but his strength was exhausted. He tried in vain to procure the re-establishment of his health; for all the remedies prescribed by the ablest physicians were wholly ineffectual. His mind afterwards lost its activity; and on the 22d of March 1799, he finished his mortal career, in the fifty-ninth year of his age. His life has been written by Jean Senebier, entitled *Mémoire Historique sur la vie et les écrits d'Horace Benedict de Saussure*, Geneva, 1801; and his *Eloge* by Cuvier for the Institute in 1810, and for the *Biographie Universelle*.

SAUVEUR, JOSEPH, an eminent French mathematician, born at La Flèche in 1653. He was absolutely dumb until he was seven years of age; and even then his organs of speech were not so fully developed as to permit him to speak without great deliberation. Mathematics were the only studies he had any relish for, and these he cultivated with extraordinary success; so that he commenced teacher at twenty years of age, and rose so rapidly in vogue, that he had Prince Eugene for his scholar. He became mathematical professor in the royal college in 1686; and ten years

afterwards was admitted a member of the Academy of Sciences. He died in 1716; and his writings, which consist rather of detached papers than of connected treatises, are all inserted in the *Memoirs of the Academy of Sciences*. He was twice married; and by the last wife he had a son, who, like himself, was dumb for the first seven years of his life.

SAVAGE, RICHARD, a man rendered famous by the singularity of his misfortunes, and by the elaborate life which Dr Johnson has written of him, was the son of Anne Countess of Macclesfield and of the Earl of Rivers, and was born on the 16th of January 1696-97. His mother, after a strenuous defence by her counsel, was convicted of adultery, and having thus separated herself from her husband the Earl of Macclesfield, she resolved to disown her unfortunate offspring, and treated him ever after with the most unnatural cruelty. (See Cunningham's edition of Johnson's *Lives of the Poets*.) She delivered him to a poor woman to educate as her own, and after a vain endeavour to send him secretly to the plantations, she had him apprenticed to a shoemaker. Savage having discovered some letters which revealed to him his birth and the cause of its concealment, he became suddenly dissatisfied with the situation of a shoemaker, and resolved to solicit his unnatural parent for the means of pursuing a more distinguished career than had hitherto been afforded him. But he could neither soften the heart of this woman nor open her hand. Having received a tolerably good education, and being endowed by nature with a turn for poetry, he wrote *Woman's Riddle* and *Love in a Veil*, which, if they did not bring him much money, at least brought him friends. He next wrote the tragedy of *Sir Thomas Overbury*, which brought him in a sum of L.200. But Savage was a bad manager, and was ever in distress. He next published a volume of *Miscellanies*, and was on the fair way to fame, when he was suddenly condemned to be hanged for having killed a man in a drunken frolic. Despite his mother's anxiety to have the sentence of the law carried into effect, he was at last pardoned by the intercession of the Countess of Hertford. He now had his revenge upon his mother, by publishing his poem of the *Bastard*, 1728, which displays such an exalted tone of thought, an energy of expression, and a refined severity of sarcasm, which places it considerably ahead of his other writings. At last interest prevailed over maternal affection, and she resolved to allow him a pension of L.200 a year. He was taken into the family of Lord Tyrconnel, with whom he lived for some time in the greatest amity. He wrote a poem entitled the *Temple of Health and Mirth*, in 1730, on the recovery of Lady Tyrconnel from a languishing illness; he dedicated, in strains of the highest panegyric, a poem called the *Wanderer*, in 1729, to his noble benefactor. A poem on the birthday of the Queen, entitled the *Volunteer-Laureate*, and written in 1731-32, brought him a pension of L.50 a year, but her death, on the 20th November 1737, deprived him of all hopes from the court. But the friendships of Savage were not generally of very long duration. He suddenly quarrelled with Lord Tyrconnel in 1735, which again set him adrift penniless upon the world. His friends now resolved to procure him permanent relief, and he was accordingly despatched into Wales, where he was to live the rest of his life in quiet retirement, at the rate of L.50 a year. Whether it was that the destitute and profligate life which he had lately led had unconsciously enchanted him, or, what is more probable, that he entertained secret longings after that distinction to which he felt his birth entitled him, he, at all events, resolved to deceive his friends, by simply retiring to write another tragedy, and again return to London to bring it upon the stage. He at length reached Swansea, where, after living about a year, he returned to Bristol, on his way to London. While in Bristol he was feasted and caressed for a time, and money was even raised

Savage.

Savali
||
Savannah.

to carry him to London, but Savage had the misfortune to weary out his Bristol friends. His clothes were worn out: his appearance was shabby: his presence was disgusting. He was at last thrown into prison for a debt of L.8, which he owed to the mistress of a coffee-house. Here, notwithstanding much kindness, he chafed and pined away, till at last, being seized with a fever, he expired on the 31st of July 1743, in the forty-sixth year of his age. He was buried on the 2d of August, in the churchyard of St Peter, Bristol, adjoining the gaol, where his remains rest without any external mark to indicate them.

SAVAII, an island in the South Pacific, the largest of the Navigator's or Samoan group. S. Lat. (of the southern point) 13. 49., W. Long. 172. 29. Its length is about 50 miles, and its breadth varies from 20 to 30. The structure is volcanic; and the surface rises gradually from the shore to the peaks, thrown up by extinct craters. One of these, near the centre, rises to the height of 4000 feet, and is conspicuous to a wide distance round about. The interior has never been explored. Savaii enjoys a very fertile soil, which produces, without culture, coffee, sugar, indigo, and other plants. There is one safe harbour on the north shore. Pop. estimated at 20,000.

SAVAN DROOG, a strong hill fort of India, in the territory of Mysore, 19 miles W. of Bangalore, and 53 N.E. of Seringapatam. It occupies a bare granite rock, 4004 feet above the sea, in the midst of dense forest, and cleft into two distinct summits at the top. It is about 8 miles round, and the sides are very steep. It was stormed by the British in 1791; and after the fall of Tippoo Sultan in 1799, was garrisoned by a native force, but this was withdrawn on account of the unhealthiness of the place.

SAVANNAH, the largest town in the state of Georgia, United States of North America, on the right bank of the river of the same name, about 18 miles above its mouth and 90 W.S.W. of Charleston. It occupies a perfectly level site, on a bluff about 40 feet above the river, and consequently does not present, when viewed externally, a very striking appearance. The town, however, is one of the finest and best laid out in the southern States. Broad streets intersect each other at right angles, and at every alternate corner there is a public place, circular or oval in form. These, as well as the streets, are lined with shady rows of Pride of India trees, which give the town an exceedingly beautiful appearance, and have procured for it the title of the Forest City. Many of the houses are built of wood, but in others brick is employed. The public buildings are not very remarkable, the finest being a Presbyterian and an Episcopal church. A plain monument has been erected to General Green, and another of a very splendid appearance to Pulaski, who were both distinguished, while the latter fell, in the attack on the place when held by the British in 1779. Savannah has an exchange, theatre, court-house, jail, arsenal, market-house, and custom-house. There are also several academies, hospitals, banking establishments, and insurance offices. No important manufactures are carried on, but the commerce is much greater than the appearance and size of the town would lead the stranger to expect. The reason of this is to be found in the number and extent of lines of communication which centre at Savannah, and convey to it the produce of the inland country. Besides the river there are 1053 miles of railways in various directions, bringing down from the interior cotton and other goods; while steamers ply regularly to New York, Philadelphia, Bermudas, the British West Indies, &c. Savannah exports to the Northern States, Great Britain, and France, cotton, rice, and naval stores; to the Gulf ports, rice; and to Cuba and San Francisco, timber and rice; while it imports from England railway iron, hardware, salt, &c.; from the Northern States, groceries and dry goods; and from

New Orleans and the West Indies, molasses, sugar, whisky, fruits, &c. Between September 1st 1851 and September 1st 1852 the receipts of cotton at Savannah were 351,566 bales, and the exports 353,068 bales. In the same year there were exported 39,929 casks of rice, and 25,508,500 feet of timber. The harbour of the town is not equal to the accommodation of its rapidly-increasing business; and the river is obstructed about a mile below by some sunken wrecks. But great efforts are being made by the citizens, with some assistance from the United States government, for the improvement of the river. The shipping of the port, June 30th 1852, had an aggregate tonnage of 13,053 registered, and 10,909 enrolled and licensed. During the year ending on that day there arrived from foreign ports 117 vessels; tonnage, 49,270: and their cleared for foreign ports 147; tonnage, 61,516. Pop. (1850) 16,060; (1853) 23,458, of whom 13,714 were free, and 9744 slaves.

SAVARY, NICOLAS, a French traveller, was born at Vitre, in Bretagne, in 1750. He studied with distinction at Rennes, and in 1776 travelled into Egypt, where he remained nearly three years. During this period he was wholly engaged in the study of the Arabian language, in searching out ancient monuments, and in examining the national manners. After making himself acquainted with the antiquities of Egypt, he visited the islands in the Archipelago, where he spent eighteen months. On his return to France in the year 1780, he published *A Translation of the Koran, with a short Life of Mohammed*, in 1783, 2 vols. 8vo; *The Morality of the Koran, or a Collection of the most excellent Maxims in the Koran*, 1784; and *Letters on Egypt*, in 3 vols. 8vo, in 1785. The Arabic grammar of Savary will not bear comparison with that of De Sacy. Savary's descriptions are in general faithful, but are in some instances too much ornamented. He has been justly censured for painting modern Egypt and its inhabitants in too high colours. He died on the 4th of February 1788.

SAVE (anc. *Savus*, Germ. *Sau*), a river of the Austrian empire, rises in Carniola, near Laibach, on the eastern slope of the Carnic or Julian Alps; and flows eastward, separating for some distance Carniola from Styria, then traversing Croatia, and finally separating the Austrian Military Frontier from the Turkish provinces of Bosnia and Servia. It falls into the Danube at Belgrade, after a course of 550 miles. Its chief affluents, which all join it from the south, are the Kulpa, at its junction with which it becomes navigable for vessels of 150 tons, the Unna, Verbas, Bosna, Dvina, and Morava. The Save forms an important means of communication to the countries which it waters, and by it their agricultural productions are easily and cheaply conveyed to their proper markets.

SAVERNE (anc. *Taberna*, Germ. *Zabern*), a town of France, in the department of Bas-Rhin, on the Zorn, 19 miles N.W. of Strasburg. It stands on the east slope of the Vosges, where the Paris road descends the hill in zig-zags. The town is irregularly built and in no way remarkable, the principal building being the large castle of red sandstone, formerly a residence of the bishops of Strasburg, and now partly used for barracks; the old parish church; and the *château*, converted in 1852 into an hospital for widows. Woollen cloth, hosiery, leather, hardware, bricks, tiles, &c., are made here; and there is some trade in timber from the Vosges. Saverne is an ancient place, and was formerly fortified. It suffered very much during the Thirty Years' War; and its fortifications were destroyed in 1696. Pop. 6407.

SAVIGLIANO, a town of the kingdom of Sardinia, in the province and 8 miles E. of Saluzzo, in a fertile and beautiful region, watered by the Maira and other affluents of the Po. It is for the most part well built, and has a

Savary
||
Savigliano.

Savile

fine market-place, lined with colonnades, and another very handsome public square. There are four good churches, a very beautiful oratory, several convents, a college and various schools, an infirmary, foundling hospital, and other benevolent institutions. There are also here a theatre and large cavalry barracks. The manufactures of the town consist of woollen cloth, linen, silk, leather, candles, &c., and these articles, along with cattle, form the staple of the trade. Savigliano is a favourite place of residence of the nobility and gentry of the vicinity. It was formerly fortified, and has still some remains of the ancient walls. Here was fought a battle in 1799, in which the Austrians were defeated by the French. Pop. 16,500.

SAVILLE, GEORGE, Marquis of Halifax, one of the greatest statesmen of his time, was born in 1630. Some time after his return from his travels he was created a peer, in consideration of his own and his father's merits. He was a strenuous opposer of the bill of exclusion, but proposed such limitations of the Duke of York's authority as should disable him from doing any harm either to church or state; as the taking out of his hands all power in ecclesiastical matters, the disposal of the public money, and the power of making peace and war, and lodging these in the two houses of parliament. After that bill was rejected in the House of Lords, he pressed them, though without success, to proceed to the limitation of the duke's power, and began with moving that, during the king's life, he might be obliged to live 500 miles out of England. In August 1682 he was created a marquis, and soon after made privy-seal. Upon King James's accession he was made president of the council; but on his refusal to consent to the repeal of the test act, he was dismissed from all public employments. In that assembly of the Lords which met after King James's withdrawing himself the first time from Whitehall, the marquis was chosen their president; and upon the king's return from Feversham he was sent, together with the Earl of Shrewsbury and Lord Delamere, from the Prince of Orange to order his majesty to quit the palace. In the convention of parliament he was chosen speaker of the House of Lords, and strenuously supported the motion for the vacancy of the throne, and the conjunctive sovereignty of the prince and princess, upon whose accession he was again made privy-seal. Yet, in 1689, he quitted the court, and became a zealous opposer of the measures of government till his death, which happened in April 1695. Grainger observes that "he was a person of unsettled principles and of a lively imagination, which sometimes got the better of his judgment. He would never lose his jest, though it spoiled his argument, or brought his sincerity or even his religion in question. He was deservedly celebrated for his parliamentary talents; and in the famous contest relating to the bill of exclusion, was thought to be a match for his uncle Shaftesbury. The pieces he has left us show him to have been an ingenious, if not a masterly writer; and his *Advice to a Daughter* contains more good sense in few words than is perhaps to be found in any of his contemporary authors." His lordship also wrote the *Character of a Trimmer*; *Anatomy of an Equivalent*; *A Letter to a Dissenter*; *A Rough Draught of a New Model at Sea*; and *Maxims of State*; all which were printed together in 1 vol. 8vo. Since these there were also published under his name, *The Character of King Charles II.*, 8vo.; *The Character of Bishop Burnet*; and *Historical Observations upon the Reigns of Edward I., Edward II., Edward III., and Richard II., with Remarks upon their Faithful Counsellors and False Favourites*.

SAVILLE, Sir Henry, a learned Englishman, was the second son of Henry Savile, and was born at Over Bradley, near Halifax, in Yorkshire, on the 30th of November 1549. He entered Merton College, Oxford,

in 1561, where he took the degrees in arts, and was chosen fellow. When he took his degree of master of arts in 1570, he read for that honour in the *Almagest* of Ptolemy, which procured him the reputation of a man eminently skilled in the mathematics and the Greek language, in the former of which he voluntarily read a public lecture in the university for some time. In 1578 he travelled into France and other countries, where, diligently improving himself in all useful learning, he returned a most accomplished gentleman. On his return he was made tutor in the Greek tongue to Queen Elizabeth, who had a great esteem for him.

In 1585 he was made warden of Merton College, which he governed thirty-six years with great honour, and improved it by all the means in his power. In 1596 he was chosen provost of Eton College. James I., upon his accession to the crown of England, expressed a great regard for him, and would have preferred him either in church or state; but Savile declined it, and only accepted the ceremony of knighthood from the king at Windsor, in 1604. His only son Henry dying about that time, he thenceforth devoted his fortune to the promotion of learning. In 1619 he founded two lectures or professorships in Oxford, one in geometry and the other in astronomy, which he endowed with a salary of L.160 a year each, besides a legacy of L.600 to purchase more lands for the same use. He also furnished a library with mathematical books, near the mathematical school, for the use of his professors. He gave besides several rare manuscripts and printed books to the Bodleian Library, and a quantity of Greek types to the printing press at Oxford. After a life thus spent in the encouragement and promotion of science and literature, he died at Eton College on the 19th of February 1622, in the seventy-third year of his age, and was buried in the chapel there. On this occasion the university of Oxford paid him the greatest honours, by having a public speech and verses made in his praise, which were soon afterwards published in quarto, under the title of *Ultima Linea Savilii*.

The highest encomiums were bestowed on Savile by all the learned of his time; by Casaubon, Mercerus, Meibomius, Joseph Scaliger, and especially the learned Bishop Montague, who, in his *Diatriba* upon Selden's *History of Tythes*, styles him "that magazine of learning, whose memory shall be honourable amongst not only the learned but the righteous for ever." His works are *Four Books of the Histories of Cornelius Tacitus, and the Life of Agricola, with Notes upon them*, in folio, dedicated to Queen Elizabeth, 1581; *A View of certain Military Matters, or Commentaries concerning Roman Warfare*, 1598; *Rerum Anglicarum Scriptores post Bedam*, 1596, a collection of the best writers of our English history; *The Works of St Chrysostom, in Greek*, in 8 vols. folio, 1613. This is a very fine edition, and composed with great cost and labour. In 1618 he published a Latin work, written by Thomas Bradwardin, archbishop of Canterbury, against Pelagius, entitled *De Causa Dei contra Pelagium et de virtute Causarum*, to which he prefixed the life of Bradwardin. In 1621 he published a collection of his own *Mathematical Lectures on Euclid's Elements*, in 4to; *Oratio coram Elizabetha Regina Oxoniæ habita*, anno 1592, printed at Oxford in 1658, in 4to. He translated into Latin *King James's Apology for the Oath of Allegiance*. He also left several manuscripts, written by order of King James, all which are in the Bodleian Library. He wrote notes likewise upon the margin of many books in his library, particularly Eusebius's *Ecclesiastical History*, which were afterwards used by Valesius in his edition of that work in 1659. Four of his letters to Camden are published by Smith, among Camden's Letters, 1691, 4to.

Savile.

SAVINGS BANKS.

Introductory Remarks.

A SAVINGS BANK may be defined as an institution for the receipt of small sums of money, to be placed at compound interest, and returned on demand. It may, and in practice it frequently does, embrace other and collateral objects—such, for example, as the granting of annuities—but its primary characteristics are (1), the capitalization of interest on the sums deposited; (2), the holding of those sums at call—whether with or without notice, as the specific rules may prescribe.

Pithy sayings about the universal duties of frugality and foresight are much older than the earliest attempts to broaden the path of their performance by giving increased facilities of access to the multitude. The first essays of this kind, when at length they were made, seem always to have connected themselves with ideas of compulsion rather than of persuasion. In England, in the first half of the eighteenth century, for instance, the most favourite project was to effect a legislative substitution of savings for poor's-rates; by passing "acts of Parliament which," as Defoe says, "shall make drunkards take care of wife and children; spendthrifts lay up for a wet day; lazy fellows diligent; and thoughtless, sottish men careful and provident."¹ Francis Maseres, in 1771, took a somewhat wiser course when he proposed to give powers to incorporate the ratepayers of any parish for the purpose of receiving "some part of the money people could save out of their wages," of investing this money in stock, and of granting deferred annuities to the depositors. A bill based on this proposal, open as it was to grave objections of detail, passed the Commons, but was rejected by the Lords. Precisely the same fate attended another, but compulsory, scheme advocated a few years later by the Rev. John Acland, of Exeter, for establishing a great "Provident Society," to which all persons between twenty-one and thirty years of age, not being landowners, were by law to belong.

The earliest "savings banks," properly so called, with which we are acquainted are those of Hamburg, founded in 1778, and of Berne, about nine years later in date. Both were restricted, more or less closely, to the use of domestic servants, handicraftsmen, and the like. The Hamburg bank, too, formed part of a general scheme for the administration of poor's funds. Neither of them appears to have attracted any attention in England.

For the first British savings bank we must look to the suburban village of Tottenham, near London, where a "children's bank" was begun by Priscilla Wakefield, in 1798, followed by one for adults in 1804. The first in Scotland was established by the Rev. John Muckersy, of West-Calder in Mid-Lothian, in October 1807, under the title of "West-Calder Friendly Bank." But the virtual founder of savings banks in the British empire was Dr Henry Duncan, minister of Ruthwell, in Dumfriesshire, whose attention was first attracted to the subject in reading one of the many tracts on matters of social economy written by John Bone.

I. HISTORY AND STATISTICS OF THE SAVINGS BANKS OF GREAT BRITAIN AND IRELAND.

Between the little experiment for children at Tottenham in 1798, and that decisive experiment at Ruthwell, in Dumfriesshire, in 1810, which placed the value and success of savings banks beyond question, the only very noticeable institution of this kind was that founded at Bath, exclusively

for domestic servants, in 1808. The originator was Lady Isabella Douglas. The sums receivable from any one depositor were limited to L.50. On the attainment of that sum facilities were offered for its investment in the public funds, so that a new account might be immediately opened. Interest was allowed at the rate of 4 per cent. per annum. The scheme was for a time so prosperous that, in 1813, an endeavour was made to convert the "servants' bank" into a general bank for savings, but the attempt did not then succeed, apparently from the want of satisfactory channels for investment. It was not until 1815 that the "Provident Institution of Bath," afterwards designated the "Bath Savings Bank," was effectively established.

When Dr Duncan began his enterprise at Ruthwell he had for his encouragement the general good character and industrious habits of the people amongst whom he laboured. On the adverse side was the want of resident heritors to support the scheme at its outset, and also the circumstance that a majority of the best parishioners were already members of friendly societies, the obligations of which they were barely able to meet. In about four years, however, the benevolent and energetic founder had the satisfaction of seeing in his bank a fund amounting to L.1160, and bearing interest at 5 per cent. Dr Duncan started with the wise axioms that "the very prejudices of the people should be carefully consulted, and treated with tenderness and delicacy," and that they should themselves take a share in the management. As to the time and amounts of the deposits, his first intention was to leave them to the depositors, and to avoid any fines or forfeitures, such as were imposed by the Friendly Societies; but eventually he found it desirable to make a regulation, that upon any account being once opened with the bank, there must be a deposit of at least four shillings annually, under the penalty of forfeiting one shilling. At Ruthwell, as at most other places in which savings banks were established at an early period, there were many considerable deposits in single sums, which had been long hoarded, without interest and without security.

Edinburgh followed in December 1813, but, curiously enough, without knowing what had been done at Ruthwell, although the proceedings there had already attracted attention in many other parts of the United Kingdom. The chief mover in the matter at Edinburgh, Mr J. H. Forbes, was familiar with the experiments at Tottenham and at Bath many years before, but knew nothing of Dr Duncan's exertions in Dumfriesshire, just as Dr Duncan himself was unacquainted (until after the first appearance of his *Essay on Parish Banks*) with the little bank at West-Calder, established by the Rev. John Muckersy three years earlier. Within the first nine months, the Edinburgh bank—which, for a considerable period, continued to be a branch or section of the "Society for the Suppression of Beggars"—numbered 106 depositors. Within three years, it had received savings from 1837 several depositors, amounting in the whole to L.8316, 14s., of which sum L.1460 had been exchanged for interest notes of L.10 each, on the bank of Sir William Forbes and Company. During the first year, 4 per cent., but afterwards 5 per cent., was the rate of interest both on current accounts and on the notes. No deposit of less than one shilling was received. The transfer to Messrs Forbes' bank, or withdrawal by the depositor, became necessary as soon as the amount standing to the credit of any account reached L.10. The yearly summary for this initiative period ran thus:—

Savings
banks of
various
English
towns.

The banks of Bath (on the establishment of its "Provident Institution" in January 1815), Southampton (in November of the same year), Exeter (in February 1816), and Hertford (in the following March), rank at once amongst the earliest and amongst the most successful of those which were established in English towns prior to the legislative regulation of savings banks. The early experience of all of them presents matter which has still its interest; but we restrict ourselves to the two latter. The rules adopted at Exeter limited the sums to be paid in by any one depositor during the first year to L.50; to the like amount during the second year; and to L.25 in each succeeding year. It allowed 4 per cent. interest. But its characteristic feature was the establishment of about sixty receiving offices in all parts of Devonshire, on a plan which entailed little expense—the only item of charge being for printing and postage or portage—and which largely increased the business of the parent institution in the county town. Most of the receivers were clergymen. The expenses were defrayed out of a fund which had been raised by voluntary subscription. Within two years this bank had received 1380 deposits from 946 depositors, amounting in the aggregate to L.14,525, and bearing interest amounting to L.246. It had repaid the sum of L.984 to 73 depositors, leaving a balance to depositors' credit of L.13,709, in addition to a surplus of L.372 on the establishment and expenses fund. The bank at Hertford had been preceded by one of a peculiar kind, called "The Sunday Bank," which had been established by a benevolent vicar—the Rev. Thomas Lloyd—some two or three years earlier. Sums from sixpence to two shillings, paid by parishioners, chiefly of the labouring class, to the vicar, after morning service on Sundays, amounted for several years to upwards of L.300 a year; but these sums (prior to March 1816) were always returned to the depositors every New Year's Day, with interest, usually at the rate of *twelve per cent.*, a rate arising, not of course from profitable investment exclusively, but from the addition of certain benefactions to the legitimate interest. On the establishment of the savings bank, the "Sunday Bank" became, so to speak, a feeder to it. In the evidence given by Mr Lloyd before the Lords' Committee on the Poor Laws of 1817, he assigned, as one of the causes which had promoted the success of the banks, the evils arising from Benefit Clubs or Friendly Societies as then constituted:—"For there is almost always," he said, "a regulation that when two-thirds of the members chose to assemble and unanimously agree to break up the clubs, they can; the consequence is, that the other third, the old members, who ought to be deriving an assistance during the last period of their lives from these clubs, are deprived of it. We have had . . . six clubs broken up within these two years in the neighbourhood of Hertford." He also stated, as one of the difficulties he had to contend with, a very general fear on the part of the labourers "of the persons employing them knowing what they can save; that is, what they can live upon. There certainly always has been a fear that, if it were known, their masters and employers would reduce their wages. . . . It almost invariably happens that, when a deposit is made by a labourer, the great anxiety is, that nobody should know it; and . . . one of

VOL. XIX.

History
and Statis-
tics.

our regulations is . . . secrecy. The man at the next door does not know that his neighbour puts into the savings bank. . . . The labourers bring their book on Sunday instead of Saturday; they bolt the door regularly, and bring the book out with great secrecy, for the entry to be made in it."

The first savings bank established (in March 1815) in Ireland was that of Stillorgan, called the "Parochial Bank," and was due to the exertions of the Rev. John Reade, who, on removing shortly afterwards to Clondalkin, established a second bank there. In both places the small deposits of the peasantry were kept in the bank, each depositor having his special receptacle,—("the poor," wrote Mr Reade, "are always pleased to see their money at every period they make their deposit")—until they amounted to L.1, when they were invested in stock. Both these original banks, like the earliest banks of England and of Scotland, have long since been absorbed in larger institutions of later date. The third Irish bank, that of Belfast, was opened in January 1816, and received, within the first year and three-quarters, 3428 deposits from 646 depositors, amounting in the aggregate to L.4416. The sums withdrawn during this period amounted but to L.1518. "The class of people," says the first report, "who generally deposit money in this bank is that of servants; there were a great many spinners at the commencement, but the misfortunes of their trade obliged them to desist." The Belfast bank continues to flourish.

At the end of the year 1816, there were in England and Wales 74, and in Ireland 4 savings banks, each managed according to its particular rules, and all resting, as respects the security of the deposits, upon personal knowledge and confidence between depositors and managers. In July 1817, the first parliamentary enactments for the regulation of savings banks were passed, the one being 57 Geo. III., c. 130, intitled "An Act to Encourage the Establishment of Banks for Savings in England;" the other, 57 Geo. III., c. 105, intitled "An Act to Encourage the Establishment of Savings Banks in Ireland." Both measures required that the rules of every savings bank should be deposited with the clerk of the peace. In England, every depositor was restricted to the investment of sums not exceeding L.100 in the first year, and L.50 in each succeeding year; in Ireland, the limit was L.50 in any year. The trustees and managers of the banks were prohibited from receiving any profits, and were empowered to pay over the monies received from depositors into the Bank of England or of Ireland respectively (in sums not less than L.50 in England, or L.100 in Ireland), to the account of the Commissioners for the reduction of the National Debt, and as "the fund of the banks for savings." The Commissioners were to invest the monies so received in 3 per cent. bank annuities, and were to issue debentures bearing interest at 3d. per cent. per diem (L.4, 11s. 3d. per annum), payable twice a year, in May and November, and were to lay annually before Parliament an account of all monies received and stock purchased. Finally, in Ireland, the trustees might place a portion of their deposits on interest with bankers, provided the sums so placed did not exceed one-fifth of the whole amount of deposits, but no similar power was given by the English act.

The next session brought its "Act to amend an Act 58 Geo. III., c. 48. Establishment of Banks for Savings in England" (58 Geo. III., c. 48), by which the forms of the debentures were altered; power was given to the justices at sessions to reject the rules deposited with the clerk of the peace; and the payment into any savings bank by ticket or number, without disclosing the name of the depositor, of any sums exceeding L.10 in the year, was prohibited.

In March 1818, 164 banks in England and Wales had

History and Statistics.
State of the savings banks in England and Wales in 1818.

paid to the account of the National Debt Commissioners sums amounting in the aggregate to L.657,187, with which stock had been purchased to the amount of L.816,547. The largest payment—viz., L.32,000—was that of the Exeter Bank; the smallest—viz., L.160—that of the bank at St John's, Wapping, near London. Two months later, the number of banks in England and Wales had increased to 227, the amount of payments to L.949,835, bearing an annual interest of L.43,336, and the stock purchased to L.1,182,385. The sums similarly invested by seven Irish banks amounted in March 1818 to L.12,553, producing in stock L.13,322. In the year ending 5th January 1819, the payments from Irish banks, the number of which is not stated in the parliamentary return, amounted to L.50,030, producing in stock L.55,304.

Further alterations of the law.

An act of 1820 (1 Geo. IV., c. 83) repealed so much of the preceding acts as related to the issuing of debentures; directed that interest should be calculated twice in the year, and carried to account as additional principal; and enabled charitable societies to deposit with the Commissioners either the whole or any portion of their funds. The Irish banks continued to be regulated by 57 Geo. III., c. 105, until, in 1824, one act, for the first time, comprised both kingdoms. This act (5 Geo. IV., c. 62) extended to Ireland the main provisions of the act last mentioned. It repealed so much of the 57 Geo. III., c. 105, as limited the deposits to L.50 in one year, and permitted trustees to place any portion of their funds, not exceeding a fifth, in the hands of a banker. It also repealed so much of the 57 Geo. III., c. 130, as provided that deposits should not exceed L.100 in the first year, and L.50 in any succeeding year; and also so much of the 58 Geo. III., c. 48, as allowed deposits by ticket or number to the amount of L.10 a year, and enacted that in future no anonymous deposits should be made. The deposits of any one depositor, either in England or in Ireland, were thenceforth restricted to L.50 in the first year, and to L.30 in any year afterwards; and it was provided that the whole should not exceed L.200, exclusive of interest. This act further repealed that recent provision of 1 Geo. IV., c. 83, which authorized charitable societies to deposit their funds.

Statistics of savings banks in Great Britain and Ireland, Nov. 20, 1824.

The new law came into force on the 20th November 1824. The aggregate investments of each depositor were then first subjected to legal restriction. At that date there had been received by the National Debt Commissioners, from the trustees of savings banks and friendly societies (during a period of seven years and a quarter), a total sum of L.12,361,919, 6s. 4d.—viz., in Great Britain, L.11,636,271, 4s. 4d.; in Ireland, L.725,648, 2s. The repayments, during the same period, interest included, amounted to L.632,670, 18s. The total amount of stock standing to savings bank account in the Commissioners' names was L.13,384,350, 17s. 7d., the actual cost of which had been L.11,544,017, 8s. 2d.; the gross amount of interest received thereon by the Commissioners was L.1,817,382, 3s. 10d., and the gross amount of interest paid or credited by the Commissioners to savings banks and friendly societies was L.1,540,557, 4s. 11d.

The "Governing Statutes"—9 Geo. IV., c. 92.

We now arrive at the first of the present "governing statutes" of savings banks, viz., the 9 Geo. IV., c. 92, passed on the 28th July 1828, and intitled, "An Act to Consolidate and Amend the Laws relating to Savings Banks," which repealed all the statutes previously in force. This act then provided that the rules of every savings bank should be entered in a book, be deposited with the clerk of the peace for the county in which such bank was held, and be then submitted to a barrister appointed by the Commissioners, to be by him certified and laid before the justices in quarter-sessions, who might reject the same or any part thereof. If admitted, the rules became binding on

depositors and officers. Such of its minor enactments (still in force) as appear to be important, will be mentioned in a subsequent section of this article.

History and Statistics.

The following table will show the progress of the banks (exclusive of friendly societies) under the working of the legislation of 1824 and 1828, until the period (1833) of the passing of the important act of 3 Will. IV., c. 14:—

Year ending 20th Nov.	Amount received by the Commissioners from Savings Banks.	Interest Paid or Credited to Savings Banks.	Total Amount Credited to Savings Banks in the Year.	Total Amount of Repayments during the Year.	Balance to Credit of Savings Bank at close of each Year
	L.	L.	L.	L.	L.
1817-1824 ..	10,814,379	1,538,456	12,352,836	632,208	11,720,629
1825...	1,207,229	562,759	1,769,988	232,909	13,257,708
1826 ..	539,268	592,390	1,131,659	1,251,149	13,135,218
1827...	859,734	615,516	1,475,250	421,759	14,188,708
1828 ..	1,058,621	675,753	1,734,374	564,579	15,358,504
1829 ..	396,159	563,983	960,142	1,527,151	11,791,495

1831...	487,512	550,116	1,037,629	1,199,182	14,698,635
1832 ..	556,355	543,013	1,099,368	1,381,118	14,416,885
1833 ..	894,493	554,257	1,448,751	540,842	15,321,794
Total of 17 years ..	17,314,855	6,751,721	24,066,581	8,741,787	...

A more striking illustration of the value of the savings bank system can hardly be conceived than that which is afforded by the figures of the memorable years 1826 and 1829-32, as they stand in this table. These are the only years in which the nett funds of savings banks *decreased*, until we reach the commercial crisis of 1847.

The salient provisions of the act of 1833, intitled, "An 3 Will. IV., Act to enable depositors in Savings Banks and others to c. 14 purchase Government Annuities through the medium of (1833). Savings Banks," &c., are—(1.) The powers given to the National Debt Commissioners for the purchase of government annuities, not exceeding L.20 per annum, nor to be granted on the life of any nominee under fifteen years of age, on depositors' account. This portion of the act occupies clauses 1 to 24 inclusive, and clauses 26 and 27, and has since been repealed. (2.) The obligation imposed on all executors, administrators, and assignees of savings bank officers to pay any money owing by such officers to any savings bank before any other debt. (3.) The repeal of so much of the 9 Geo. IV., c. 92, as relates to the withdrawing of deposits and re-depositing; and the enactment in lieu thereof, that no sums exceeding L.30 in the aggregate shall be deposited in any one year. (4, and finally.) The enactment, in clause 25, "That it shall be lawful for the said Commissioners . . . from time to time, and as they shall think fit, to sell and dispose of the bank annuities and Exchequer bills, or any part thereof which may be now standing, or may hereafter stand in their names, . . . in pursuance of the said act, . . . and with the proceeds thereof to purchase in lieu thereof any other description of Bank annuities, or annuities for terms of years, or Exchequer bills." Another act, 5 and 6 Will. IV., c. 57, intitled, "An Act to extend to Scotland certain provisions of an Act of His late Majesty to consolidate and amend the Laws relating to Savings Banks," &c., repealed c. 57 the 59 Geo. III., c. 62, except in relation to such savings banks as had been established under it, and had not conformed to the provisions of 9 Geo. IV., c. 92. With respect to such banks, the former act was to continue in force until the time of such conformation.

In each year, from 1834 to 1841 (which year completed the first quarter of a century from their legal establishment), the nett amount of the deposits in savings banks continued to increase, as will be seen if we resume the table of their transactions with the Commissioners for the reduction of the National Debt, in similar form:—

The total number of savings banks in the United

Kingdom at this date (20th November 1841) was 555, viz., in England (including Guernsey and Jersey), 428; in Wales, 23; in Scotland, 28; in Ireland, 76. The total number of current accounts in these banks was 841,204; of which 824,162 belonged to individual depositors, 8778 to charitable institutions, and 8624 to friendly societies. The aggregate amount of the deposits, with interest, in 554 of these banks (the remaining bank having made no return), was L.24,474,680, of which sum L.22,915,940 stood to the account of individual depositors, L.478,096 to that of charitable institutions, and L.1,080,653 to that of friendly societies. The average amount standing to the credit of each individual depositor was L.28; to that of each charitable society, L.54; to that of each friendly society, L.131. The details for the respective portions of the United Kingdom were as follows:—

* Mean average.

As compared with the population, there was at this period, in England, 1 depositor to every 22 inhabitants; in Wales, 1 to 58; in Scotland, 1 to 52; in Ireland, 1 to 105.

The remarkable success of the savings bank system, so greatly beyond any the most sanguine expectations that could have been preconceived of it, had of course its alloy. There had been several instances of defalcation by actuaries of the banks. Although not covered by the guarantee bonds exacted by law, the amount of these defalcations was inconsiderable. But it was none the less obviously important that effective precautions should be taken to preclude their recurrence. Other points of anxiety presented themselves in respect to the exercise of the powers vested in or

assumed by the National Debt Commissioners of varying, for other than savings bank purposes, the securities held in trust by them on savings banks account; and also in respect to the considerable and increasing difference between the total amount of the debt owing by the Commissioners to the savings banks, and that of the securities in which that debt was invested. In the course of the eager controversy which was then carried on, it was alleged, on the one hand, that the deficit was the inevitable consequence of the parliamentary enactments as to the interest to be allowed by the Commissioners to the banks; and, on the other, that no deficiency would have existed had there been no trafficking for extraneous purposes in the securities in which the money of depositors was invested.

It is obvious that the immediate, or almost immediate, investment of the deposits as they are received by the Commissioners—which investment is the fundamental principle of our savings banks' legislation—entails the frequent purchase of stock at high prices in prosperous times, when deposits are pouring in; and that immediate repayment of deposits on demand—which repayment is also and equally fundamental—must, conversely, involve the frequent sale of stock at low prices in times of depression, when deposits fall off and withdrawals are numerous.

The following table exhibits (1) the amount of interest received by the National Debt Commissioners on account of the investments made for savings banks in each year from 1817 to 1843 inclusive; and (2) the amount of interest paid and credited by the Commissioners to the trustees of savings banks during the same period, at the parliamentary rate of L.4, 11s. 3d. per cent., until the year 1828 inclusive; and at that of L.3, 16s. 0½d. from 1829 to 1843 inclusive:—

The total excess paid to the banks under the L.4, 11s. 3d. per cent. rate was L.744,362, 17s. 4d.; that paid under the L.3. 16s. 0 $\frac{1}{2}$ d. rate, to the year 1843 inclusive, was L.1,333,897, 4s. 4d. In 1844, Mr Goulburn's Act (7 and 8 Vict., c. 83), reduced the rate of interest to be allowed to the trustees, from the close of the then current year, to L.3, 5s. per cent.; and enacted that the rate to be allowed to depositors should not exceed L.3, 0s. 10d. per cent. per annum. As that act was at first framed, it proposed to reduce the interest to trustees to L.3, 1s. 4d. per cent., and the maximum interest to depositors to L.2, 13s. 9d. per cent.; but the opposition of the principal banks led to a compromise.

The excess of interest paid to the banks during the last year of the old rate (ending 20th November 1844) was L.101,673, 7s. 3d., making the total excess up to that date L.2,179,933, 8s. 11d. The like excess paid during the first year of the new rate (ending 20th November 1845) was L.20,185, 4s. 3d.

Provisions
of 7 and 8
Vict., c. 83,
with re-
spect to re-
sponsibi-
lity of trust-
ees.

Another important alteration in the law of savings banks, introduced by the Act of 1844, was that relating to the responsibilities of trustees and managers. The Act of 1828 declared that no such officer "should be personally liable, *except for his own acts or deeds*, or for anything done by him . . . *in cases where he should be guilty of wilful neglect or default*." Prior to that Act of 1828, it had been judicially declared that "deposits are made by parties, not on the faith of the person acting as actuary or cashier, but upon the faith of the gentlemen who act as trustees. . . . If, therefore, the clerk or other person employed by them is guilty of peculation, they are themselves liable for any defalcation which may ensue." The Act of 1844 provides "that no trustee or manager of any savings bank shall be liable to make good any deficiency which may hereafter arise in the funds of any savings bank, *unless such persons shall have respectively declared, by writing under their hands*, and deposited with the Commissioners for the reduction of the National Debt, *that they are willing so to be answerable*; and it shall be lawful for each of such persons, or for such persons collectively, to limit his or their responsibility to such sum as shall be specified in any such instrument. Provided always that the trustee or manager of any

History
and Statis-
tics.

such institution shall be, and is hereby declared to be, personally responsible and liable for all monies actually received by him on account of, or to and for the use of such institution, and not paid over or disposed of in the manner directed by the rules of the institution; and an abstract of the above provisions shall be enrolled as one of the rules of the institution." This change also was opposed—but apparently on insufficient grounds—by some of the leading banks. It was further enacted that deposits not exceeding L.50, exclusive of interest, belonging to persons dying intestate, and to whom no letters of administration shall be taken out within one month of decease, may be paid to the widow or other person entitled; and that disputes arising between any bank and a depositor, or the representatives of a depositor, shall be referred to the barrister appointed under the act.

As far as relates to *Ireland*, the provision of 7 and 8 Vict., c. 83, which we have just recited, with respect to the responsibility of trustees and managers, was repealed, four years afterwards, by the 11 and 12 Vict., c. 133, for the purpose of enacting in lieu thereof, "that after the 20th November 1848, any trustee or manager of a savings bank in Ireland who has declared or shall declare, in writing under his hand, deposited with the Commissioners for the reduction of the National Debt, that he is willing to be answerable for a specific amount only, *such amount being in no case less than L.100*, shall not be liable to make good any deficiency which may thereafter arise in the funds of such savings bank, beyond the amount specified in such writing;" with a like proviso to that contained in the preceding act with respect to monies actually received by any individual trustee. This act of the 11 and 12 Vict. also provided that the rules of every savings bank in Ireland shall specify certain days, not less than two in every year, for the production at the bank of the pass-book of every depositor, subject to the penalty of the surceasing of interest in case of failure; and it further enacted, "that if it shall appear to the satisfaction of the Commissioners that the clauses of the said recited act and of this act, or the orders, directions, and regulations of the said Commissioners, signified by the comptroller-general to the trustees of any savings bank in Ireland, have not been complied with . . . it shall be lawful for the Commissioners to close the account of such savings bank, and to discontinue the keeping any further account with the trustees thereof;" until they shall see cause to determine otherwise.

The latest enactment bearing upon the law of savings banks is the 16 and 17 Vict., c. 45, intitled "An Act Vict., c. 45, to Consolidate and Amend the laws, and to grant additional facilities in relation to the Purchase of Government Annuities through the medium of Savings Banks, and to make other provisions in respect thereof." This act permits contracts to continue to be made by depositors for the purchase of annuities through the medium of savings banks, but practically it severs such contracts from the ordinary business of those institutions, and makes them a special section of that of the National Debt Commission.

The extensive discussions to which the introduction of the act of 1844 gave rise, have had very important consequences. Until the date of those discussions, no account of savings banks' transactions had ever been rendered by the Commissioners in detail, either to Parliament or to the public. It then, for the first time, appeared by papers laid before the House of Commons by Mr Goulburn (then Chancellor of the Exchequer), that transactions in stock, to the amount of several millions, had been effected, not for savings bank purposes, but for the general financial purposes of the State. Thus, it was shown, that in the years 1828-44, savings bank stock, amounting to L.8,166,551, was sold, and other stock, amounting to L.8,557,000, was purchased. Of the stock sold, considerably more than half (viz.,

Summary
of transac-
tions in
savings
bank stock,
1828-44.

SAVINGS BANKS.

661

History and Statistics. L.4,156,901 three per cents.) was sold at prices ranging from 86 to 90. Of the stock bought, one-sixth (viz., L.1,420,000 three per cents.) was bought at prices ranging from 96½ to 100½, and nearly two-sevenths more (viz.,

L.2,379,900 three per cents.) at prices ranging from 92½ to 98. The details, as laid before the House of Commons, are as follows:—

STOCK SOLD, 1828-44.				STOCK PURCHASED, 1828-44.			
Three per Cents.	Prices.	Three and a half per Cents.	Prices.	Three per Cents.	Prices.	Three and a half per Cents.	Prices.

				519,600	...	81,100	...
Total ..7,155,051	..	1,011,500	...	4,319,500	...	4,237,500	...

During the same period, about L.19,888,100 exchequer bills were held, of which about L.13,041,550 were disposed of. Both stock and cash-balances were frequently employed in the purchase of exchequer bills when at a discount; and it is shown by the returns that such purchases were continued daily for considerable periods of time. We have here a serious element imported into savings bank finance, as heretofore managed, which stands wholly apart from those contingencies of investment and repayment that are inseparable from the savings bank system.

In 1842, the total amount which had been paid by the banks to the National Debt Commission was L.26,460,042,¹ and the total amount of interest paid or credited to the banks, L.12,730,765, making, in the aggregate, L.39,190,814. The total repayments made by the Commission to the banks amounted to L.14,653,844, and the total balance standing to the credit of the banks was L.24,536,791. At this period the number of savings banks in the United Kingdom was 555, and the aggregate number of their depositors 824,162, exclusive of 17,402 societies. The progress from 1842 to 1857 may be thus epitomized:—

Statistics of savings banks, 1841-57.

Year ending 20th Nov.	Amount received by the Commissioners from Savings Banks.	Interest paid or Credited to Savings Banks.	Total Amount Credited to Savings Banks during the Year.	Total repayments during the Year.	Balance to Credit of Savings Banks at Close of the Year.

Comparison of aggregate deposits with aggregate withdrawals, 1841-57. During the seventeen years, 1841 to 1857 inclusive, there have been nine years (viz., 1841 to 1846 inclusive, and 1851-53 inclusive), in which the sums deposited with the savings banks have exceeded the sums withdrawn; and eight years (viz., 1847 to 1850 inclusive, and 1854-57 in-

clusive), in which the sums withdrawn have exceeded the sums deposited. In the two years, 1847-48, the amount of the withdrawals was more than five millions (L.5,201,433) in excess of the amount of the deposits. Nor has the state of affairs in this respect at any subsequent period at all approached that which existed prior to 1846. So that, on the whole seventeen years there has been a nett excess of withdrawals over deposits, amounting to L.3,114,436; the aggregate deposits having been but L.116,159,005, against an aggregate of L.119,273,441, deposits and interest withdrawn. No better exemplification of the power of compound interest need be desired than that which results from the juxtaposition of these figures, with those which indicate the comparative balances held by the National Debt Commissioners to the credit of the savings banks, at the beginning and end of the period referred to. That balance, at the close of the year 1841, was L.24,536,791; at the close of the year 1857 it was L.35,255,722.

The specific progress of the interest on the savings banks' fund has been shown in detail up to the close of the year 1843 inclusive, at which period an excess of the interest credited to the banks beyond that realized by the Commissioners had accumulated to the amount of L.2,078,260, 1s. 8d. We now resume that account to the close of the year 1857:—

Continuation of comparative statement of interest on savings banks securities received and credited by the Commissioners.

Year ending 20th Nov.	Dividends on Savings Banks' Stock and other Securities received by the Com- missioners.			Interest Paid or Credited by Com- missioners to Sav- ings Banks.			Excess of Interest Paid to the Banks.

The following official table will exhibit in detail the transactions, during the seventeen years 1841-57, of the depositors with the banks on the one hand, and of the banks with the Commissioners on the other:—

¹ Disregarding the fractions of a pound, which, here and elsewhere, occasion a trivial difference between the sums severally and their aggregate as stated in the text and tables.

History
and Statis-
tics.“Separate
surplus
fund” ac-
count.

The amount standing to the credit of the “separate surplus fund” appears (by a return dated 16th March 1857) to have reached, at the close of the year 1855, L.335,598, 10s. 2d., of which sum L.322,288, 17s. 10d. belonged to the English and Welsh banks; L.318, 1s. 9d. to Scottish banks; L.10,691, 10s. 7d. to Irish banks; and L.2300 to banks in the smaller islands of the British seas. On this surplus account no interest is paid by the National Debt Commissioners.

Classifica-
tion of de-
posits in
the United
Kingdom,
according
to amount.

In 1857 the total number of banks in the United Kingdom was 597, with 1,341,752 depositors, of whom 1,139,919 had sums not exceeding L.50—viz., in the

aggregate, L.13,960,203, being on the average L.12, 4s. 11d. for each depositor; 130,204 had sums exceeding L.50, but under L.100—namely, in the aggregate, L.3,982,919, being on the average L.68, 19s. 9d. for each depositor; 70,159 had sums exceeding L.100, but under L.200—viz., in the aggregate, L.9,719,339, being on the average L.138, 10s. 8d. for each depositor; and 1470 had sums exceeding L.200—viz., in the aggregate, L.321,562, being on the average L.218, 15s. for each depositor. The average deposit for the whole number of depositors was L.24, 11s. 7d. The details stood thus:—

Class of Depositors in the order of their respective amounts.	No. of Depo- sitors in each Class.	Amount Depo- sited in each Class.	Average Depo- sit in each Class.	Proportion per cent. of Depo- sitors in each Class.	Proportion per cent. of Depo- sits in each Class.
1. Not exceeding L.20	846,203	L. 4,848,447	L. 5.729	63.067	14.699
2. Exceeding L.20, but not exceeding L.50	293,716	9,111,756	31.022	21.890	27.624
3. Exceeding L.50, but not exceeding L.100	130,204	8,982,919	68.991	9.704	27.231

Totals	1,341,752	32,984,023	24.582

Social
classifica-
tion of de-
positors.

On the interesting point of the social classification of depositors, the attainable information is but partial. A return of this kind was made to the House of Commons in 1853, but out of the whole number of savings banks then existing in the United Kingdom—namely, 576—172 failed to make the return required. It appears, however, that

the returns made by the other 404 banks embrace not only 70 per cent. of the whole number of savings banks, but 78½ per cent. of the whole deposits in savings banks in the United Kingdom, and 79½ per cent. of the whole number of individual depositors. These returns may be thus epitomized:—

I.—Number of Depositors in each Class.

Social Classification of Depositors in 404 Savings Banks of the United Kingdom.	IN ENGLAND.				IN WALES.	IN SCOTLAND.	IN IRELAND.	Total in the United Kingdom.

Unquestionably valuable as is this classification of the social position and employment of depositors, it would absorb too much of our space to pursue it into further detail. In the *Report of the Select Committee on Savings Banks* of 1858, the tables we have quoted are supplemented by a calculated abstract of the depositors and the deposits in the 172 banks which omitted to make returns on this point, on the basis of those made by the other banks; and also by a general summary, comparing alike the returns actually made and those so calculated. To these we must refer the reader who may be desirous of pursuing the inquiry.

During the last few years the expenses of local management have varied from an average of 6s. 6d. to one of 6s. 8d. per cent. throughout the United Kingdom. Thus,

in 1852, there were 479 banks in England and Wales, with an aggregate expenditure of £91,800, or, on the average of the whole, at the rate of 6s. 6d. per cent. In Scotland, 43 banks expended £5500, or at the rate, over the whole, of 8s. 8d. per cent. In Ireland, the expenditure of 51 banks amounted to £7200, or on the average, 9s. 11d. per cent. For the whole United Kingdom there were then 573 banks, expending £104,500, or on the average 6s. 8d. per cent. In 1856, when the banks of England and Wales numbered 498, instead of 479, their aggregate expenses amounted to £101,800 (against £91,800 in 1852), being at the rate of 6s. 7d. per cent. In Scotland, 46 banks expended £7400, being at the rate of 7s. 8d. per cent.; and, in Ireland, 51 banks expended £7600, being at the rate of 9s. per cent. The details are as follow:—

Expenses

Defalcations from the funds of savings banks.

The many defalcations from the funds of savings banks by the frauds of their officers, sometimes followed by the failure and dissolution of the banks concerned, have been attended with an amount of public mischief which cannot be estimated by the mere sums of money that have been actually lost to the depositors. These, if compared with the aggregate of savings bank transactions, will seem of small amount; and in most instances vigorous exertion has been used, by trustees and others, to lighten the burden to the shoulders least capable of sustaining it. But the suffering thus occasioned to individuals and to families has still been great, and the hindrance to the good working of the system yet greater and more lasting. In some districts the discouragement thus given to provident frugality will outlive the existing generation.

We believe that a review of all the cases of defalcation that have occurred since the commencement of savings banks would lead to the conclusion that, in nearly every instance, the most common and obvious precautions against fraud have been disregarded. The necessary limits of this article will not admit of such a review, even in its briefest form. But we may glance at a few of the more conspicuous cases.

Failure of the Rochdale Bank, 1849.

No case in the annals of savings banks is more deplorable than the failure of the Rochdale Bank in 1849, though the frauds of George Howarth, who had been its actuary from 1822 until 1849, and died in that office, without any suspicion of his malpractices having been excited. Here (it has been proved in evidence before a parliamentary committee) the *sole control* of the bank was left to its actuary ("who represented himself," said one witness, "as filling the office really as a matter of charity," and who "managed to deceive every body by an appearance of wealth") for a period of at least twelve years, and the official returns to the National Debt Commissioners were sometimes signed by men "*who did not know that they were managers*" until the actuary assured them they were so at the moment that they were asked to sign. No real audit of the accounts ever took place. When Howarth died the liabilities of the bank to depositors were L.100,403; its deposits with the National Debt Commissioners were L.26,898; its cash in hand, L.1788; making the total assets L.28,686, and leaving a deficit of L.71,717. Ultimately the trustees and managers raised by subscription a sum of about L.17,000; and the sale of the actuary's property produced about L.17,000 more,—raising the total assets to nearly L.63,000, which paid the depositors 12s. 6d. in the pound.

Other defalcations in savings banks, 1851-57.

Between 1851 and 1857, inclusive, defalcations occurred in the savings banks of the following towns:—Bradford (Wilts), Bromley, Dunmow, Leicester, Ongar, Newport (Isle of Wight), Rugby, Runcorn, Southport, West London, and Yoxall. In all these cases an investigation was instituted,—in the majority of them by the employment of Mr W. H. Grey, an accountant very conversant with the business of savings banks, and recommended for the task by the National Debt Commissioners. The general result of these inquiries is quite in harmony with the obvious conclusions from the Rochdale case. Great laxity of book-

keeping; absence of any effective audit; signature of the annual returns without even cursory examination,—these are the common features of almost every case. At Dunmow (where the defalcations were small and much more than covered by the surplus fund), reports Mr Grey, "I find that in one instance a balance of about L.80 stood for several years in duplicate in the books, and must therefore have been counted twice over in the classified lists of those years; . . . and the required total must, on these occasions, also have been made up fictitiously." . . . "For several years most of the ledger entries were made with pencil only; and although the accounts so posted which remained open were afterwards copied with ink into another book, yet those which were closed during that period still remain only in pencil."

At Newport, Isle of Wight (where the deficiency amounted to L.8156), "Fictitious documents, purporting to be signed by depositors, giving notice of their intention to withdraw a part, or the whole of their deposits, have been produced by the secretary, on the faith of which cheques have been signed by the attending director without seeing the pass-book, and without ascertaining whether such sums were really standing in the ledger or not. These cheques have been entrusted to the secretary for delivery to the depositors at any time they might call for them, instead of insisting on personal attendance during bank hours. . . . Some of the sums for which cheques were thus obtained were not standing at all in the bank books; or, having formerly stood there, had already been withdrawn; others were standing there, but no real notice of withdrawal had been given by the depositors, who never received the cheques so obtained. . . . In some cases fictitious accounts have been raised in the ledgers, and closed again immediately with fraudulent repayments, and in other cases, in which the amounts had been previously withdrawn, the dates of the real withdrawals have been altered into those of the fraudulent ones." After illustrating other fraudulent practices at this bank, Mr Grey adds that no comparison of the cash-book and the ledgers had ever been instituted, and that "the system pursued has practically left the whole control of the receipt and payment of about L.30,000 a year to one individual." But in 1849, when the failure of the Rochdale bank, and several frauds in other banks, aroused the closer attention of the National Debt Commissioners and of their comptroller to the methods pursued in the transaction of the local business, it was suggested to all the trustees of savings banks throughout the kingdom that depositors' pass-books should be called in and compared with the bank ledgers. The trustees at Newport speedily adopted this suggestion, and established the practice of having the "balance-book" (*i.e.*, the list of balances due to depositors prepared at close of each year) always on the table when the bank was open, and of comparing it with every pass-book that came in, marking both pass-book and balance-book with the attending manager's initials. This made it necessary that the balance-book should contain *all* the open accounts, which it had never done before. Mr Grey thus explains the new deception that was adopted to conceal the deficiency in the funds:—"At the annual examination both ledger and balance-book were duly placed in

Dunmow savings bank.

Newport savings bank.

Effect of the Rochdale failure on the methods pursued at Newport.

History and Statistics. the hands of the trustees or directors; but when they had satisfied themselves that all the balances had been correctly transferred, they shrank from the laborious task of adding together two or three thousand amounts, and invariably left that duty to the secretary . . . trusting to the correctness of his addition. . . . In point of fact the addition of each page was correct, but the total of each page was brought into a summary-page at the end; and in doing so L.1000 was dropt in one place, L.1000 in another, in the capital column, and L.20 here and L.30 there, in the interest column, with some odd money to make up the required difference, and thus the total amount was made to agree with the actual assets of the bank. In 1852 a still bolder step was taken. Instead of altering the sums brought forward in so many different places, only two sums were reduced by L.1000 each, but L.6000 was miscast in the addition of one of the columns of the summary-sheet, and the total amount was thus kept down to the required sum. From these practices it will be perceived how imperfect a system has been pursued, and how little it was calculated to prevent or discover fraud." In this Newport case the amount received from the surety of the late actuary was but L.100. The assets of the bank were L.58,622, its liabilities L.66,778. No subscription appears to have been made towards supplying the deficiency. The depositors received a dividend of 17s. 6d. in the pound.

Rugby bank.

Farringdon-street bank, London.

As to the Rugby Bank, Mr Grey reported that the former actuary "annually fabricated the classified statement of balances required by the National Debt Office, so as to make it appear that the liabilities of the bank corresponded exactly with its assets;" and as to the Farringdon Street, or "West London" Bank, that "there is no sign whatever that the ledger entries have ever been called over with the cash-journal. The consequence is, that the ledgers are full of errors;" . . . and added that "the scattered manner in which about 5000 open accounts are mixed with more than 18,000 closed ones, in twelve large volumes," increased the difficulty of investigating them. In this case, in fact, the investigation was never fully carried out. The amount due to depositors on the 20th November 1855, appeared to be L.96,577, and the total amount of assets L.95,024, leaving a gross deficiency of L.1553, a portion of which was known to exist independently of the fraud which had been committed. The reporter had good reason to tell the trustees: "You may congratulate yourselves that the deficiency is not greater than it appears to be; with the opportunities which have been afforded, and with so large a fund to work on, a great deal more mischief might as easily have been done; that which has been accomplished is not irre-mediabable."

This, indeed, as respects the actual magnitude of the losses, might be alleged of nearly all the cases of savings bank defalcation. The trustees and managers of the St Martin's Bank, accordingly, in their petition to the House of Commons against the proposed bill of 1853, said that "out of the 522 savings banks then established in Great Britain, there have been only six at which any loss whatever has been sustained by depositors since the year 1814 (comprising the entire period within which all the much-talked-

of failures, with the exception of the more recent case in the Isle of Wight, have occurred;)" and proceeded to show that the amount of loss sustained by the depositors of those six banks amounted in the aggregate to but L.49,373,—viz. Rochdale, L.37,433; St Helens, 4000; Spilsby, L.2436; Reeth, L.147; Poole, L.5176; Newtown (Wales), L.180; that in 14 other cases of default occurring during the like period, "all the depositors are stated to have been paid in full, either out of the assets of the banks, or by subscription raised amongst the trustees and managers, or the inhabitants of the neighbourhood where the banks were located;" and, finally, that "the percentage of these losses, when taken upon the gross total of sums received and paid by the savings banks in Great Britain, including interest credited, since their first establishment in 1817 (amounting to upwards of L.73,000,000), will be found not to exceed 1s. 4d. upon every L.100;" and they add the inquiry,—“Where, in this or in any other country, in any public or commercial institutions, involving money transactions of equal number and extent, can so just and satisfactory account of a stewardship be rendered, as is here shown?” But it must not be forgotten, that it would be at least equally difficult to produce an analogous series of defalcations so largely facilitated, if not absolutely caused, by the neglect of elementary principles of precaution and supervision. And pecuniary loss (we repeat) is not, in this matter, the just measure of public injury. Nor can it be very difficult to do in *all* savings banks (with more or less of completeness) what has already been so effectively done in the best of them. Improved organization and methods of working need to be diffused, not invented. To this part of the subject we have now to turn.¹

Organization and Management.

II. ORGANIZATION AND MANAGEMENT OF THE SAVINGS BANKS OF GREAT BRITAIN AND IRELAND.

The legislation which at present governs the savings banks of the United Kingdom is contained, or chiefly contained, in the several statutes, 9 Geo. IV., c. 92; 3 Will. IV., c. 14; 5 and 6 Will. IV., c. 57, 7 and 8 Vict., c. 83; 11 and 12 Vict., c. 133; and 16 and 17 Vict., c. 45. The main provisions, and the immediate circumstances of each of these acts of Parliament, have been recited in the course of our historical summary. No consolidated statute as yet exists. It is necessary, therefore, to give a connected view of these various and scattered enactments, in their direct bearings upon the daily business of a savings bank.

I. *Formation*.—Savings Banks are only to be established with the approval of the Commissioners for the reduction of the National Debt, or, on their behalf, of the comptroller-general, or assistant-comptroller, acting under the said commissioners. The proposed rules of the bank to be established are to be submitted, in duplicate, to the consulting barrister appointed by such Commissioners, who, on approval, is to return one copy to the originators, and to transmit the other to the Commissioners. A fee of one guinea is payable to the barrister. The rules are then to be filed in the National Debt Office, and to be preserved in a book at the bank. The trustees are to forward a certificate of their own ap-

pointment, together with their signatures duly authenticated. They have then to apply for the form of instructions with respect to their appointment of a London agent, who alone is to transact their pecuniary business with the Commissioners, both in the payment and the withdrawal of deposits into or from the Bank of England.

II. *Management*.—Savings banks are usually governed by trustees and managers, at first elected by the founders, and duly registered in the Office of the National Debt Commissioners; and empowered to fill up vacancies in their own body from time to time, subject to like registration. In some banks the managers are styled a "committee," and are elected annually by the founders and other "patrons" of the bank. Such trustees and managers are not to have any salary or benefit whatever from the bank they administer. They may appoint and dismiss all needful officers for the transaction of the business, and may fix their respective salaries or other remuneration. All paid officers so appointed and all treasurers must give security to the comptroller-general of the National Debt Commission for the just execution of their respective trusts, on a form of bond furnished to the trustees by the Commissioners, and to such amount as may be determined by not less than two trustees and three managers, which determination shall be recorded on the minutes of the acting committee, and the bond be lodged with the comptroller-general. But neither Commissioners nor comptroller have any power to question the validity or adequacy of the security offered. It has been—as we have shown in our historical retrospect—expressly enacted that no trustee or manager shall incur personal responsibility, otherwise than for acts of personal and wilful neglect or default, *unless* he shall have declared in writing, under his own hand, to the National Debt Commissioners his willingness to be so responsible, which responsibility he may limit to a certain amount. This is the present state (1859) of the law as respects England and Scotland; but, *in Ireland*, every trustee and manager is liable, *ex officio*, and indefinitely, for any deficiency that may occur in the funds of his bank, unless he shall have signed a document limiting his liability to any sum not less than £100.

III. *Investment of Deposits*.—Monies deposited in savings banks are to be invested, to the credit of the Commissioners for the reduction of the National Debt, in the Bank of England or Bank of Ireland exclusively. Trustees are empowered to make their investments with the Commissioners in any sums not less than £50, after notice signed by two trustees, and to retain in their hands such sums only as may from time to time be required to meet withdrawals and other exigencies. The Commissioners are empowered to invest the monies paid to their account either in bank annuities or in exchequer bills.

IV. *Methods, Limitations, and Conditions of Deposits, and of their Withdrawal*.—All persons who are about to become depositors in a savings bank must state their names and residences, together with their respective profession, business, occupation, or calling; and must sign a declaration of the following purport:—

"In pursuance of an Act of Parliament of the 9 Geo. IV., c. 92, § 34, I, A—B—, of —, do hereby declare to the Trustees and Managers of the Savings Bank established at —, that I am desirous, on my own behalf, to become a depositor in the said savings bank, and that I am not, directly or indirectly, entitled to any deposit in, or benefit from, the funds of this or of any other savings bank in Great Britain or Ireland, nor to any sum or sums standing in the name or names of any other person or persons in the books of the said savings bank above mentioned." [If the depositor belong to any friendly society, he must then add:—"Save and except such benefit as I may be entitled to from being a member of a friendly society, legally established."] Witness my hand this day

of 18 . Signed by the said A—B— in presence of me —."

If the declaration so made shall be false, or if the depositor shall afterwards place money in more than one savings bank at a time, the whole of his deposits become forfeited. The *minimum* deposit is not fixed by law, but ranges in the various banks from 1s. to 5s., according to their respective regulations. The *maximum* of the deposits of any one year is £30 (exclusive of interest thereon, and irrespectively of any withdrawals during the year); and that of the total sums receivable from any one depositor (inclusive of interest) is £150. When, by the addition of compound interest thereto, such maximum sum shall have reached £200, interest thereon shall cease. In respect, however, of accounts which, prior to the passing of the act of 9 Geo. IV., c. 92, viz., on the 28th July 1828, already amounted to or exceeded the sum of £200 in the whole, interest and compound interest are still payable. Every depositor, on making his or her first deposit, is to receive a copy of the rules, and a depositor's book or pass-book, in which shall be entered such first deposit, and all subsequent deposits; all notices of withdrawal, and sums withdrawn. The pass-book must be produced at the bank whenever any business is transacted, and must also be exhibited once at least in every year for the purpose of being examined. This book is the depositor's receipt and voucher; and its production by the depositor, or by any person authorized by the depositor, is at all times, in the absence of any previous claim to the deposit-money made in writing, a sufficient authority for the repayment of money, notwithstanding the bankruptcy, insolvency, or other legal disability of such depositor. On the closing of the account, the book is to be re-delivered to the bank. Persons under twenty-one years of age are empowered to make and withdraw deposits in the same

manner as if they were of full age. Any married woman may receive money in respect of any deposit made by her, unless her husband shall have given notice in writing of the marriage, and shall claim payment to himself. Trust deposits are to be invested, jointly, in the name of the trustee and of the person interested; and the receipts, or joint-receipt, of both must be given in order to the validity of a repayment, except in case of the insanity or imbecility of the person on whose behalf the deposit shall have been made; upon proof of which, repayment may be made to the trustee. Friendly societies, legally established, may invest their funds in savings banks to any amount; and charitable societies or institutions may deposit to the amount of £100 in any one year, and to the amount of £300 in the whole, exclusive of interest. Disputes between the trustees of a savings bank and any depositor, or any executor, administrator, next of kin, or creditor or assignee, of a depositor, who may have become bankrupt, are to be referred in writing to the barrister appointed under the acts of Parliament to certify the rules of savings banks; who, on such reference, may inspect books and documents, and administer an oath to witnesses; and whose decision shall be final. Deposits may be transferred to or from other savings banks upon due notice. The regulations applicable to the withdrawal of deposits differ, more or less, in the various banks. At Glasgow, for example, no notice is required. But usually a notice of from seven to twenty-one days, according to the amount involved, must be given of the claim to repayment.

V. *Interest on Deposits*.—Since the 20th of November 1844, the rate of interest payable by the Commissioners for the reduction of the National Debt to the trustees of savings banks has been fixed at £3, 5s. per cent. per annum, and deposits the maximum rate to be paid by the banks to depositors at £3, 0s. 10d. per cent. per annum. The precise rate per cent. assigned to depositors depends, therefore, on the rule of each bank respectively, provided always that it shall not exceed £3, 0s. 10d. on deposits invested with the National Debt Com-

tion of in-
terest.

missioners; and the precise rate actually *received* by depositors depends on the methods of calculation, which in various banks have a wide range of difference. At Edinburgh, for instance, interest at L2, 17s. 9d. per cent. is allowed on sums of 1s., 2s., 3s., 4s., and 5s., and on multiples of 5s., not only by months and weeks, but by portions of a week. Thus, the date of "Tuesday" in each week is used for *Monday, Tuesday, and Wednesday*; and that of "Friday" for *Thursday, Friday, and Saturday*; and interest is credited wherever it amounts to the tenth of a penny. On Mondays or Thursdays the depositor of course loses one day's interest; on Wednesdays or Saturdays he gains one day's interest. At Cork, again, interest at the rate of L2, 17s. 0½d. is calculated every four days on all deposits of 5s. and upwards; no sum less than 5s. being received at that bank. At Manchester, depositors receive L3 per cent. per annum on every entire sum of 10s. sterling, calculated only by calendar months, and from the 20th day of each month; no interest being allowed on any less sum than 10s., or on any fractional part of 10s., or for any less period than one month. Finally, the Perth savings bank—a quite exceptional instance—paid interest to most of its depositors, in the year 1857, at the rate of L4, 5s. per cent. per annum, having transferred more than four-fifths of its capital from the National Debt Commissioners to the Union and Central Banks of Scotland, under the powers of a special proviso introduced into its rules in the year 1847 (at which period a very high rate of interest was given by the Scottish joint-stock banks), in these terms:—"It shall be lawful for the trustees of this bank, at the request of any depositor or depositors, to invest the monies deposited, or to be deposited, by them, in any of the banks of Scotland, incorporated by statute or royal charter, for the benefit of the several depositors, under the powers contained in the 12th section of the Act of the 9 Geo. IV., c. 92; and the interest to be paid on the deposits so invested will be fixed from time to time by resolutions of the committee of management, and which will be binding on the depositors without the necessity of the rate of interest being entered in their pass-books. The interest fixed by the committee of management will be computed yearly, up to the 20th day of November in each year, and added to the principal; the whole sum bearing interest thereafter." The *average* rate of interest paid by English and Welsh banks to their depositors is L2, 18s. 9d.; that paid by Scottish banks, L2, 17s. 9d.; and that paid by Irish banks, L2, 16s. 5d.; the average of the United Kingdom being L2, 18s. 8d.

Annuities.

VI. *Annuities*.—The trustees and managers of savings banks may receive from depositors, or from any other persons, any sum or sums of money (subject to the limitations hereafter mentioned), for the purchase of government annuities, immediate or deferred. All such sums received shall be entered in a book provided for that purpose, in the presence of the payer, who shall sign a declaration, in the form directed by the Commissioners for the reduction of the National Debt, that he or she neither possesses nor is entitled to any annuity or annuities under the statutes 3 Will. IV., c. 14, and 7 and 8 Vict., c. 83, exceeding in the whole, with the annuity now applied for, the sum of L30 per annum. The purchaser shall then receive a book containing an abstract of the rules, with a certificate of the contract for the annuity, signed by two trustees or managers, and also an account of the money paid, attested by the signature of the actuary. No annuity can be contracted for upon the life of any person who is under the age of fifteen; and no annuity or annuities can be possessed by any one individual exceeding, in the whole, the sum of L30 per annum; nor can any annuity be granted of less amount than L4 per annum. Should any individual become possessed at any one time of annuities granted under the provisions of the Acts of 3 Will. IV., c. 14, or 7 and

8 Vict., c. 83, exceeding in the whole the sum of L30 per annum, such annuities will immediately cease and be forfeited. Provided, nevertheless, that any married person may purchase or be possessed of an annuity not exceeding the amount last named, although an annuity of like amount may have been granted to or may be possessed by the wife or husband of such person. All contracts for annuities must be sanctioned by the National Debt Commissioners, for which purpose proof of age must be furnished to the managers of the savings bank contracted with. The money received for annuities must be paid to the Commissioners, to whom, fourteen days previous to the demand for payment of any life annuity, proof must be afforded of the existence and identity of the annuitant. All annuities when due are payable by two equal half-yearly payments; namely, on the 5th of January and 5th of July, in respect of all purchases which were completed at any time during the quarter ending on the 10th of the preceding October; and on the 5th April and 10th October, in respect of all purchases which were completed at any time during the quarter ending on the 5th of the preceding January; and so, conversely, with respect to purchases completed during the other quarters of the year. No annuity thus purchased can be transferred or assigned by the purchaser, so as to enable the assignee to receive the same during the purchaser's lifetime. If the intending purchaser of a deferred annuity, having made one or more payments on account, shall give due notice of his inability to continue such payments, the amount of the payments actually made shall (but without interest) be returned to such intending purchaser; and, in like manner, if any person who shall have contracted for the purchase of a deferred annuity shall die before the said annuity shall have become payable, the amount of his previous payments shall be repaid to his executors or administrators without interest. The acts recited, together with that of 10 Geo. IV., c. 24, §§ 40–44, impose heavy penalties for false statements, or for receiving annuities after the death of the person entitled.

VII. *Bookkeeping*.—The bookkeeping of savings banks will be best illustrated by describing *seriatim* the systems severally pursued at some of the principal banks of the United Kingdom:—

(1.) *St Martin's Place Savings Bank, London*.—Three distinct sets of journals or day-books are kept: the first, that of the auditors; the second, that of the cashiers; the third, that of the ledger-clerks; each of which sets records the entire business of the day, and all of which are compared at its close. In addition to his specific journal, each clerk has a certain number of ledgers, each of them corresponding with a certain numerical series of depositors' books. No other clerk is allowed to make any entry in these, without the express permission of the comptroller or weekly auditor. All "cash transactions with depositors," proceed the rules relating to bookkeeping (as given in evidence by Mr Boodle, the comptroller, before the Commons' Committee of 1858), "shall be first entered in the clerks' journals, cash-books, and managers' [elsewhere called auditors'] journals; and such books at the close of the business of each day shall be called over, and compared with each other by the weekly auditors and clerks, and all variations be rectified before the clerks be dismissed; and after the depositor's book has left the office, no alteration shall be permitted in the clerks' journals or cashiers' books, without reference to the managers' journal, and a careful examination of the number, name, and amount. Any alteration required to be made in a depositor's book is to be referred back to the ledger-clerk, to make the necessary correction in his journal. The ledger-clerks shall post the several entries from their respective journals into their ledgers, carefully examining the name as well as the number of each account, inserting at the same time in the 'ledgers'

check journal' the number of each account in which the transaction is so posted. The cashiers, each taking another's division, shall enter from the ledgers into the separate ledgers' check journals, against the number of each account, the amount so posted, whether receipts or payments, checking the accuracy of the additions or subtractions; such entries in the check journals being first carefully examined, both as to the numbers and the amount, with the corresponding entries in the cashiers' journals, and then cast, and the castings checked; the officers examining such entries and checking the castings signing their initials in the check journal; every variation either in numbers or amounts, before correction, being carefully examined with the managers' [elsewhere called auditors'] journals, and all errors being noted in a separate 'error-book,' kept for each division, and weekly examined and checked by the chief cashier and accountant. The total of the entries so made from the ledgers into the separate ledgers' check journals shall be collected by the comptroller, and ascertained, by a weekly examination, to agree with the total amounts of each week's receipts and payments." Further, with respect to the comparison from time to time of depositors' books with the ledgers, another rule—the twenty-fourth—directs, "That in all cases, when a depositor's book shall be first brought to the office after each 20th of November, the balance standing in the depositor's book on such 20th of November shall be ascertained by a careful examination, and by a separate addition of the interest extracted from the ledger account, to agree with the checked balance in the ledger to such period; and to certify to such correctness, and to record the date of the production of the depositor's book, the ledger-clerk examining the same shall sign his initials against such balance in the depositor's book, and also in the ledger." And the 25th rule directs, "That upon any variance, occasioned either by an error of commission or omission being found to exist between the balance in a deposit-book and the ledger, the same be at once reported to the comptroller, or in his absence to the chief cashier and accountant, before the deposit-book be returned to the depositor; and if the error shall be found to be in the ledger, a record shall be kept of the same, explaining the nature and particulars of the error occasioning such variance." It must be added, however, that *no means are taken to ensure the production from time to time of the depositors' books*, and that, in fact, a very large number remain unexamined, uncomparad, and unseen for many years.

Edinburgh
savings
bank.

(2.) *Edinburgh Savings Bank*.—The bookkeeping of the admirably managed bank at Edinburgh was thus described to the Commons' Committee of 1858 by Mr Maitland, its honorary treasurer, and the author of an excellent tract on the accounts of savings banks, published in 1841:—Depositors are received by (1) the *actuary* or his assistant, who, having obtained satisfactory answers to the needful inquiries, makes the requisite entry in the depositor's book, and passes it on to (2) the *accountant*, or his assistant, who makes the new entry in the appropriate ledger account, with the interest—to credit for a deposit, or to debit for repayment—to the 20th November next following, puts the check mark, and passes the book on to (3) the *cashier*, who has before him "two cash-books, one for division No. 1; the other for No. 2 of the ledgers," makes the new entry in his cash-book, initials the depositor's book, and passes it on to (4) the *teller*, who enters the number and sum—debtor or creditor—in his cash jotting-book, announces the depositor's name and the new-made entry, initials or gets initialed, receives or pays the amount accordingly, and returns the depositor's book to the depositor. Thus far, it will be seen, the entries in the bank's books have all been made from the depositor's book: that book has been confronted with its duplicate in the ledger, and the depositor has approved of the last entry by acting on it. No money

can be received or paid *until* these entries are so made. Mr Maitland adds, that about 250 depositors can be thus disposed of in one hour. Then, when the bank-door is shut to the public for the day: *1st*, The cash is counted; the cash-book-keeper and the teller balance with each other, and each signs his own book; *2dly*, The accountant disperses to their proper sections the reference numbers or accounts that day operated upon; and by these, from the ledgers (which are all kept in sections of thousands), obtains the individual sums; these sums he transfers to the section check-sheets, and thus has obtained in sections, from the ledgers, a balance with the cash-book to the close of that day. On each Saturday this result is recorded by sections, in a formal way, for the weekly report; in the ledgers, however, an error of one kind—namely, of addition or subtraction—might escape this check, as well as the daily check, by direct inspection; therefore, *3dly*, The ledgers are brought, once in every quarter, to a general trial balance; and *4thly*, comes the general annual balance at the 20th of each November for the annual return.

The reader will perceive that the Edinburgh system bases the bank accounts upon the pass-books; ensures the reciprocal check of four several officers in the record of each transaction; and provides, first, a weekly summary; secondly, a quarterly trial balance; thirdly, a general annual balance. Nor have the benefits of this system been confined to the place of its birth. The improvements made at Edinburgh have been copied by other savings banks, and sometimes with modifications which have been themselves further steps in advance.

(3.) *Manchester Savings Bank*.—At Manchester the Manchester depositor's pass-book goes through the hands of *five* several savings clerks on the receipt of each deposit, and of *four* on occa-
bank.

sion of each repayment; the receipt of the deposit-money occurs at the first manipulation of the pass-book instead of the last, as at Edinburgh; the receiving-clerk and the pay-clerk are always different officers; and a monthly audit is made by a professional accountant, not attached to the staff of the bank. The routine of receiving runs thus:—(1) The *counter or receiving clerk* takes from the depositor the money to be deposited and also his pass-book, in which he enters the amount both in figures and in words, and then hands the book and the money to (2) the *cashier*, who receives deposits, but makes no repayments. This officer enters the amount and the depositor's progressive number in the actuary's cash-book, signs the pass-book with his name in full, and then transmits it to (3) that particular *ledger-clerk* within whose section of progressive numbers it falls, who, first, posts the entry from it into the sectional ledger, and initials the pass-book to indicate such posting; and, secondly, enters in the ledger the amount of interest which will have accrued on this deposit up to the 20th of the following November. The pass-book proceeds (4) to the *cash-book-keeper*, who enters in the cash-book the depositor's number and name, and the amount of the deposit; he also writes his initials in the pass-book, and then hands it (5) to the *pay-clerk*, who calls out the name and the amount deposited, and returns the book to the responding depositor. The routine of repayment runs thus:—(1) The *counter or receiving clerk* takes from the depositor his pass-book, writes in it the date and the sum to be repaid, and hands it to (2) the *ledger-clerk* (a. above), who deducts that sum from the depositor's ledger-account, and writes beneath it the balance, if any, remaining in the bank; sending on the pass-book (after attaching his initials to the entry) to (3) the *cash-book-keeper*, who enters in the cash-book the amount to be repaid, and adds his initials in the pass-book, which is then handed to (4) the *pay clerk*, who takes a receipt from the depositor in a book kept on the counter for that purpose, pays the amount, signs the pass-book, and returns it to the depositor.

Organiza-
tion and
Manage-
ment.

Organiza-
tion and
Manage-
ment.

As soon as the bank has closed its doors to the public, a daily balance is taken by the following process:—The deposits and the repayments of the day are entered on prepared "sectional slips," at present forty-two in number (the number of open accounts at the date of the last return having been 41,398),—each representing a section of the accounts in sequent thousands of their progressive numbers, and a certain group of them corresponding precisely with each of the "sectional ledgers." These prepared slips—each having its column for receipts, its column for repayments, and its initial thousand printed upon it—are distributed amongst the clerks, to whom the actuary calls over from the cash-book the whole of the transactions of the day. When, for example, he calls over the deposit made by a depositor whose pass-book is numbered 21,223, the clerk who has the slip headed "21,000" writes down "223" in the margin, and so with the remainder of the numbers, as respects both the receipts and the repayments of the day. When these have been wholly called over each clerk takes his group of slips to the corresponding sectional ledger, and copies therefrom, upon the slips, each *amount* therein entered against its appropriate progressive number, using of course the deposit-column for sums received, and the repayment-column for sums repaid. The total of each column upon each slip is then handed to the actuary, and is proved to be correct when it agrees with the aggregates of deposits and repayments of the day, as recorded in the cash-book. Each day's account being added to the aggregate of all the preceding days in the current financial year, every sectional slip shows the total amount deposited and the total amount repaid upon its specific thousand of sequent accounts during the year. It is, therefore, a cheque both on the accuracy of the daily posting and on the periodical balance-sheets, and is so taken that, whilst every clerk works in its preparation, no clerk reviews his own entries. In addition to these precautions, an independent monthly audit is made by a professional accountant, who examines every cash transaction between the depositors and the bank, and between the bank and its treasurer, and every payment for expenses, and makes a monthly report to the trustees.

Cork sav-
ings bank.

(4.) *Cork Savings Bank.*—The banks of Cork, Limerick, and Carlisle have a method of bookkeeping which differs in some important particulars from those which have been mentioned, and is known as the "Craig system," having been devised by Mr John Craig, manager of the Cork Branch of the Bank of Ireland, and treasurer of the savings bank there. Mr Craig's own account of it is as follows:—"The first and distinguishing feature upon which all the others depend . . . is, that we amalgamate the interest with the principal, besides calculating it in the prospective form; we amalgamate the interest with the principal on every occasion either of a receipt or a payment. That is one point. The second point is, that each separate sum received is, with its interest, at once added to the balance which stands in the pass-book, and each repayment, with interest thereon, is deducted. . . . Further, we have duplicate or 'check-ledgers,' posted entirely by the auditor; no other person is ever permitted to make a figure in them. They are kept in a very concise manner, occasioning very little trouble, . . . from a check-journal also kept by himself. By the keeping that check-ledger, after the balance of the 20th November has been abstracted by the bookkeepers and clerks from the deposit-ledgers, the auditor is able to make a balance of all the accounts in the bank, and to make out a book showing the amount due upon each account, which book is laid upon a table in the hall, and every depositor that enters the bank has nothing to do but to look at that book, refer to his number, and see whether his balance is accurate or not. That has the advantage of being a double balance, and made from other materials. . . . Then, besides that, there is a 'separate ledger balance-book' kept . . . not

Organiza-
tion and
Manage-
ment.

made up directly from the cash paid and received, but always by the difference between the past and the present balance; . . . the auditor's book consists of two columns,—in the first he enters the past balance, and in the next the present balance. . . . I have also to state that the check which is kept upon the cashier consists of a book which has four columns. In the book he enters the past balance, the cash, the interest, and the present balance; at the end of the day every page is toted up. If you add the receipts of cash and the interest to the past balance, that will make the present balance; if it be repayments, then if you add the cash and interest to the present balance, it will be the past balance." Such is Mr Craig's exposition of his methods, as given to the Select Committee of 1858.

VIII. *Accounts and Returns to National Debt Commissioners.*—At the close of every four weeks the trustees of every savings bank have to return to the Commissioners for the reduction of the National Debt the receipts and payments of each week severally, the expenses of management, and the certified balances. Complete annual accounts are also to be rendered, made up to the 20th of November in each year, and transmitted to the Commissioners within nine weeks next thereafter. If the trustees neglect to render such accounts within the prescribed term, the Commissioners are empowered to close their account, and also (by another enactment) to publish the name of the defaulting savings bank in the *London Gazette*. A copy of the annual account is to be affixed in the savings bank office, and every depositor is entitled to receive a printed copy on payment of one penny. The Commissioners are to lay an abstract of the accounts rendered annually before Parliament; and they or their comptroller may require from trustees a detailed statement of all the expenses whatsoever which shall have been incurred in the management of any bank. In 1858 the annual accounts for the preceding financial year were due by law, on or before the 22d of January. On that day 502 banks had duly lodged them at the National Debt Office, and 102 banks had yet to furnish them. Of these, 45 were furnished during the remaining days of January; 49 others between the 1st and 22d of February; and, at the last-named date, 8 were still outstanding.

IX. *Dormant Deposit Accounts.*—There is no provision in the law of savings banks of the United Kingdom for the extinction of accounts lying dormant, however long the interval which may have elapsed since the last operation upon them, or however small the balances which they may respectively show. No complete returns, with respect to such accounts, have ever been prepared; but in 1851 Sir A. Y. Spearman, comptroller-general, called for a partial return of this kind, selecting 47 of the larger banks for the purpose, by which it appeared that in those 47 banks only there were about 52,000 accounts, which had been neither increased (otherwise than by accretion of interest) nor diminished during the five years ending on the 20th November 1850, and that the amount standing at the credit of those accounts was £665,000.

X. *Separate Surplus Funds.*—Prior to the passing of the Governing Statute of 1828, the trustees of savings banks were authorized to make rules for the application of increased stock or property; but no application of such surplus funds was to be made until ten years had elapsed from the establishment of the bank to which they belonged; one-half of such surplus was always to be reserved to answer deficiencies, and thirty days' notice was to be given to the Commissioners of any intended appropriation. The statute of 1828 directed that, within six weeks after the 20th November next following, the trustees should ascertain the amounts of their respective surplus funds, and appropriate the same in the manner provided for by their respective rules; and in the event of there being no such provision, then according to the judgment of the trustees

Improve-
ments in

tion and
Manage-
ment.

in general meeting assembled; and it was then enacted that from 20th November 1828 the surplus was to be paid over annually to the Commissioners, and that trustees and managers might claim and receive from the Commissioners, for the purposes of the institution, upon such certificate as the Commissioners should appoint, any sum of money equal to the whole, or to any part of the principal monies which might have been discharged from the account of the savings bank concerned, as surplus.¹

III. SUGGESTED IMPROVEMENTS IN THE ORGANIZATION AND MANAGEMENT OF THE SAVINGS BANKS OF GREAT BRITAIN AND IRELAND.

(1.) Conso-
lidation of
the savings
bank sta-
tutes.

The elaborate inquiries of the Commons' Committee of 1858, although they have not as yet led to any amended legislation, appear sufficiently to have established certain facts and principles which may usefully govern such legislation, whenever the subject shall be fairly grappled with by Parliament hereafter. Amongst all the varieties of opinion which the recent inquiry elicited, no one will be found to have affirmed the advantage of leaving the law of savings banks scattered, as it is at present, in a multitude of statutes, many of them partially repealed, and some of them conflicting. It may be taken, therefore, as admitted on all hands, that, as a first point of improvement, the law of savings banks should be consolidated into a single act for the whole kingdom.

(2.) Crea-
tion of a
special
commission
for the ge-
neral con-
trol of
savings
banks.

Again, however opinions may differ on the question, whether the terms of the existing statutes do or do not really confer on the Commissioners for the reduction of the National Debt, or on the Chancellor of the Exchequer as chief acting Commissioner, that large control over the investments of savings banks, which it has been in practice, for more than thirty years past, assumed that they confer, there is small likelihood of disagreement on the recommendation of the Select Committee of 1858, that, for the future, the powers and duties of the Commissioners—be they whom they may—entrusted with the superintendence of savings banks and the investment of their funds, shall be strictly and accurately defined in the consolidated statute; and that no sale, transfer, or conversion of savings bank stock shall thereafter be permitted, except for savings bank purposes, nor any addition be made to the funded national debt, without the sanction of Parliament. It may be true that in 1835, by Lord Althorp, and again in 1844, by Mr Goulburn, the sale of savings bank stock provided a fund “under the safeguard of which great reductions were made in the interest of the national debt, and the nation was relieved of an annual charge of many thousand pounds.” It may also be true that, at a much more recent period, the purchase of exchequer bills on savings bank account furnished the government with necessary supplies at a critical moment—the commencement of the Crimean war—when a loan could not have been obtained, except at a serious discount. But it is equally true that the power of thus relieving the exchequer “withdraws from the cognizance of Parliament large financial transactions during the time when they are in a course of being accomplished; and also occasions discredit to savings banks by putting them in the light of institutions burdensome to the country, when, in truth, it is plain that if their money were duly invested in consols and bills as it accrued, little or no deficiency would now exist.” The Committee recommends that for the future the National Debt Commissioners shall be relieved from the office of investing the monies of savings banks, and that this duty shall be confided to a new

commission of five members, of whom the Chancellor of the Exchequer and the Governor of the Bank of England shall always be two; the other three being nominated by the crown, and one of them being a paid member; that the expenses of the commission shall be paid out of the surplus funds belonging to the banks, that fund being invested in public securities, and the interest carried to its account. The Committee further recommends that three members of this commission shall be a quorum; that its ordinary meetings shall be held at fixed intervals; that all rules and regulations relating to the receipt and payment of monies, and the purchase and sale of stocks and other securities, shall be framed at meetings specially convened, and be subject to the approval of the Lords of the Treasury; that no sale, purchase, or variation of securities shall be made except when required for the purposes of the savings banks; and that no exchequer bills held by the commission shall be funded without the special authority of an act of Parliament.³

The amount due to the trustees of savings banks on the 20th November 1857 was L.35,255,722; the amount of the securities held by the National Debt Commissioners, at the same date, was L.34,399,082, Os. 3d., in addition to which they held an uninvested balance of L.53,200, 2s., making an aggregate of assets amounting to L.34,452,282, 2s. 3d., against an aggregate of claims amounting to L.35,255,722, which leaves a deficiency of L.803,439, 17s. 9d.⁴ Whilst, on the other hand, it has been shown, by the figures which we have already had occasion to quote in a preceding section of this article, that an excess of interest has been paid or credited by the Commissioners to the banks, beyond that received by the Commissioners upon their own investments, an excess amounting, in the aggregate, to L.2,771,051, 9s. 3d. On this point, the Committee expresses its opinion that the payment of interest and expenses of management ought not to be the source of annual loss to the State, and that by investing a portion of the capital of the savings banks in such parliamentary securities as will yield a larger return than 3 per cent., and by applying to the purpose of a “management fund” the interest of the present unappropriated surplus, and of all dormant claims after the expiration of ten years, the present rate of interest (viz. L.3, 5s.) might be provided, all expenses of the commission be defrayed, and even “a balance put by yearly, towards liquidating the deficiency arising from the transactions of former years.” Be this as it may, a review of all the circumstances of the case will, we think, go far to justify the claim advanced on the part of the banks to a parliamentary liquidation of that deficiency, irrespectively of mere expedients and possibilities.

The question as to the parliamentary replacement of the money of depositors in cases of defalcation is a widely different one. However generally the impression may have prevailed that government is in some way bound to make good such losses, it is an impression unwarranted by the existing law. On this point, however, says the Committee of 1858, “It is difficult to maintain that Parliament having released local trustees from their liability, should not be bound to provide some other guarantee for the money of depositors who have no share themselves in the management of their bank;” and it then adds the opinion that “an alternative ought to be given and freely offered to the choice of trustees, either to secure the guarantee of Parliament upon such conditions as the commission shall prescribe, or themselves to undergo the same liability in regard to savings banks as was enacted in the 9 Geo. IV., c. 92, § 9.”

Improvements in Organization and Management.

Proposed re-enactment of liability clause, 9 Geo. IV., c. 92, § 9.

This proposition does not go far. The Act of the 9th of Geo. IV. simply declares that no trustee or manager shall be personally liable, except for his own acts and deeds, and not then, *except in cases of wilful neglect or default.*" This enactment it was which limited the responsibility of trustees, although neither it nor any subsequent enactment can be truly said to have "released local trustees from their liability." Mr Tidd Pratt's definition of the existing law, as given in evidence before the Committee, was thus expressed:—"In the case of an English trustee or manager, he is not liable to make good any deficiency, unless he has signed a paper limiting the amount; and he may limit the amount. In Ireland, every trustee and manager is liable for any deficiency, except he has signed a document limiting his liability, and which limit must not be less than L.100." These words can have no reference whatever to cases of "wilful neglect or default." To revert to the enactment of 1828 (9 Geo. IV., c. 92, § 9) would, of course, remove the anomaly, whatever its extent, between the law for English and that for Irish banks, but would in no way impose on trustees that personal liability for the default of their officers, which was asserted from the bench of the Bankruptcy Court in 1826. That the existing law is doubtful and confused, the evidence of the consulting barrister under the acts abundantly proves.¹ That to return to the liability clause of the 9th Geo. IV., c. 92, would not, of itself, have the effect the Committee attributes to it will, we think, become equally obvious on closer examination.

The evidence given by the actuaries of the principal banks of the United Kingdom, however it may differ on minor points, entirely accords on the fact that the receipt and payment of deposits may be so regulated both in large and small banks as to make fraud exceedingly difficult, even in isolated cases, and impossible in systematic continuance.

(6.) Legal prescription of rules.

(7.) Official inspection.

(8.) Parliamentary guarantee.

The regulations by which this high degree of security has been here and there attained should be universally prescribed by law, and enforced by an official inspection and audit, wholly independent of the individual banks. On the report of the inspectors and the effectual audit of the accounts by the Commissioners, each bank should receive a special parliamentary guarantee for the whole amount of its deposits.

Prescribed rules for the receipt and payment of deposits to be uniformly observed, under penalty; frequent independent inspection and audit of banks by officers of the Savings Bank Commission; such an appropriation of surplus income as may, in course of time, form a guaranteed fund against casual and unavoidable losses; publication and diffusion of full and distinct accounts of the progress of savings banks;—these are measures which will go far to preclude malversation, and to maintain the invaluable public advantages of savings banks in their integrity. It will also be desirable to include in the new act an express prohibition of the use of the term "Savings Bank" by any banking partnership, or other persons, not embodied under the act. It was shown in the evidence of 1858 that banking concerns in Scotland—of unhappy celebrity—were in the habit of designating their branches as "savings banks," and did actually receive deposits from persons, who believed that they were dealing with establishments legally authorized to

(9.) Prohibition of the unauthorized use of the title "savings bank."

receive them. The Western Bank of Scotland went to the length of issuing pass-books, which bore the name, "National Security Savings Bank."²

If we include the funds of friendly societies, a sum of L.37,000,000 is already so invested, that any portion of it may be demanded from the State at any moment of pressure. The possibility of public inconvenience thus arising was one of the points which came before the recent Committee. Its deliberations on that topic resulted in the commendation to Parliament, that whenever any deposit shall amount to L.150, the Commissioners may, with the consent of the depositor, invest a portion of that deposit in the purchase, on his behalf, of L.100 stock, the interest on which shall be received by the Commissioners, and be placed to the depositor's account.

Savings Banks in Foreign Countries.

(10.) Power to the Commissioners to purchase stock on depositors' account, with consent.

IV. SAVINGS BANKS OF FOREIGN COUNTRIES.

In the brief space which remains for this concluding section of our article, our summary notices of foreign savings banks must needs be restricted to those countries only in which they have attained a wide development; and, even of these, a prominent part must sometimes be allowed to stand for the whole. Thus New York must represent the United States, and Prussia must almost suffice for Germany at large.

America possessed savings banks within a very few years of their solid establishment in Great Britain. The earliest, for example, of the sixteen banks which now exist in the city of New York dates from 1819. The aggregate amount of the 223,860 deposits paid into these banks during the year 1856 was L.3,465,512 sterling. The withdrawals during the same period amounted to L.2,707,261, showing an excess of payments over repayments amounting to L.758,251. The total amount of the accumulated deposits of 167,250 depositors, at the close of that year, was L.7,564,569; which, taking the population at that date to have been 850,000 persons, gives an average deposit of L.8, 17s. 10d. to each head of population, and of L.45, 4s. 6½d. to each depositor: the depositors being nearly as one in five of the entire population. In New York the annual expenses were L.30,957; being 17s. 7d. per cent. on the receipts of the year, and 8s. 2d. per cent. on the aggregate of the deposits held at its close.

United States of America,—New York.

The rates of interest allowed by these New York banks to depositors vary. The largest banks allow 5 per cent. to depositors on sums not exceeding 500 dollars, and 4 per cent. on larger sums. Some banks allow 6 per cent. and 5 per cent., respectively, on like sums. The rate is by law determinable according to the actual profits upon the investments of each bank, which must be made either (1) in the public stocks (of the Union, of the respective States of the Union, or of the incorporated cities of the State of New York); or, (2) in bonds and mortgages on real estate, worth double the amount lent upon them. Investments of the latter class usually realize from 6 to 7 per cent. per annum. Most of the savings banks, it is stated, restrict their investments on bond and mortgage to one-half of their aggregate deposits. As the law does not permit a greater accumulation of surplus than 10 per cent., some banks pay extra interest to their depositors from time to time, as their

¹ e. g. "69. Chairman.—Therefore, am I to understand that every Irish trustee is liable to an unlimited extent, unless he has limited it voluntarily to the sum of L.100? Yes.

"70. Whereas, in England and in Scotland, no trustee is liable, unless he has signed a paper declaring that he is willing to be so? Yes.

"71. That is the state of the law? Yes; I have put it shortly thus: in Ireland, the liability of trustees and managers for deficiencies previously to the 28th July 1828 is unlimited, unless by the rules the trustees and managers had limited their liability.

"72. . . . For deficiencies in Ireland between the 28th July 1828 (which is the date of the Act of 9 Geo. IV.) and the 9th August 1844, the liability is limited by the 9 Geo. IV., c. 92, § 9. Since the 9th August 1844 until 20th November 1848, the liability is the same as in England. Since the 20th November 1848 the liability is under the 9th Geo. IV., c. 32, § 9, except the trustee or manager has availed himself of the power to limit his liability under the 11th and 12th Vict., c. 133."

² Minutes of Evidence before Select Committee on Savings Banks (Mr W. Meikle), 2412-2436.

Savings
Banks in
Foreign
Countries.

profits augment. The amount of deposits is not ordinarily restricted; but in some of the New York banks any one account is limited to L.200, depositors being free to open as many accounts as they please, either in one bank, or in more banks than one.

According to a report presented to the Legislature of New York in 1858, the total amount of deposits in all the savings banks of the State, on the 1st of January of that year, was L.8,284,534, and the total amount of their assets L.8,777,198, showing an aggregate surplus of L.492,664. Of the collective assets, L.4,046,917 was invested in freehold securities, and L.3,901,838 in stocks; L.657,488 was cash deposited, by way of reserve, in various joint-stock banks; and L.170,954 was cash in the hands of the respective treasurers.

In drawing the attention of the recent Committee on savings banks to these statistics of the New York banks, Mr C. W. Sikes, of Huddersfield, added, that during the severe commercial crisis of 1857, "the savings banks weathered the storm without one single suspension; and that, in consequence of their having invested their money judiciously and safely, they were enabled to realize sufficient, without any sacrifice of principal, to meet every claim made upon them."¹

France.

Early history of
French
savings
banks.

The earliest French savings bank is that of Paris, which was incorporated on the 29th July 1818; Bordeaux followed the example in 1819, and Marseilles in 1821. All these banks were founded as joint-stock companies, and came, consequently, under the supervision of the Council of State. That body, however, having repeatedly expressed the opinion that a municipal organization was better suited to the character and objects of the new institutions, the fourth (in order of date) of the French savings banks was established by the town council of Troyes in August 1821. This plan has since been very generally followed; and for many years past it has been the only legal one. Three several banks—those, namely, of Avignon, Metz, and Nancy, and those only—have been formed upon a third method, being made branches of the *Monts-de-Piété*, or public pawnbroking establishments.

Until the commencement of the year 1834, the progress of savings banks in France was slow. They were then (after the lapse of sixteen years) only twenty-seven in number; but during that year the number was raised to seventy-five. Early in the following year (1835) the legislation affecting them was revised and codified; and, in its course, eighty-three new banks were founded, making the total number 158, with 121,527 depositors, and an aggregate deposit of 62,185,676 francs (L.2,487,427).

The nine years which succeeded the improved legislation of 1835 carried up the total number of banks to 347; that of depositors to 638,984; and the aggregate deposits to 392,552,467 francs (L.15,702,098). This very rapid growth was thought to need some legislative check; the maximum of deposits, on any one account, was therefore lowered, by a law of the 22d June 1845, from 3000 francs to 1500; the holding of more accounts than one was prohibited, and increased facilities were given for the conversion of deposits into stock, for the individual account of the depositor. On this last-named head, the desired result was speedily in course of attainment. At the close of 1848, the Paris bank alone had so invested L.102,392. At the eve of the Revolution of 1848, the banks were 354 in number, with 175 branch banks; the depositors were 636,951; and their deposits 358,405,924 francs (L.14,336,237). The "Days of February" brought a run upon the savings banks, and induced, on the 9th March, a decree of the Provisional Go-

vernment, raising the interest from 4 to 5 per cent., and declaring the banks to be placed "under the guarantee of national faith." But the run continued. Two days later another decree suspended cash payments, as respected all accounts exceeding 100 francs; and offered, instead, one moiety of the amount in treasury bonds, at four or six months' date, and the other moiety in 5 per cent. stock at par. The bonds at this time were at a discount of from 30 to 40 per cent.; the 5 per cents. were quoted at 73, and were rapidly declining. The Constituent Assembly, in July, decreed the total and immediate conversion into stock of all deposits anterior to 24th February, and exceeding 80 francs, the price at which the conversion was to be effected. In November, another decree opened a special "compensation account" for every depositor concerned, which credited him with the difference between the price fixed in July, and the average market price (*i.e.*, 71 francs 60 cents) of the three preceding months. "This measure," said M. Francois Delessert, president of the Paris bank, "was not merely an act of reparation; it was the salvation of the savings banks."

The immediate operation of these various enactments cannot be precisely shown. The ordinary returns for 1848 were never published. Those for 1848 and 1849, together, did not appear until 1853, and then only in a modified and incomplete form. But we gather from those returns, that during the two years above named, the accounts of 340,677 depositors were closed, and that 189,528 new accounts were opened. The aggregate amount of deposits converted into stock in the course of 1848 was 211,426,336 francs (L.8,457,053); in 1849, 101,813,184 francs (L.4,072,527). The aggregate of deposits in the savings banks at the end of 1849 was 73,917,556 francs (L.2,956,702). It appears that at this date, twenty banks only had yet to complete their funding operations under the law of July 1848. When these were finally completed, the stock account stood thus:—

Savings Banks of	No. of Stock Accounts Opened.	Amount of Capital Funded.	Amount of the Annual Dividends.
Paris	107,899	L.2,687,054	L.167,916
Departments	386,490	9,855,305	615,956
Total.....	494,389	L.12,542,359	L.783,872

It deserves remark, that at the periods of greatest excitement, even during the terrific combats of June 1848, the deposit-receiving business of the savings banks was never really at a stand-still. The smallest sum ever received by the Paris bank on a deposit day, from the date of its first establishment, was that which came in on the 2d July 1848, immediately after the great struggle. But even on that day 121 depositors made small payments, which amounted, in the aggregate, to 12,749 francs (L.510). The year 1850 witnessed a rapid progress throughout the country, or nearly throughout it,—for twenty-five of the banks are not included in the official accounts. The total deposits of the 340 banks which made returns amounted at the close of 1850 to L.5,396,680. In 1851, the whole legislation of the subject came under the review of the Assembly, and a law was passed which enacted, (1) That no new deposit shall be received on any account already amounting to 1000 francs, interest included; (2) That whenever by accretion of interest any account shall exceed that maximum, it shall be reduced, if not by the depositor himself, then by an investment in stock on his account; and, (3) That the interest should be reduced from 5 to 4½ per cent. In May 1853, a further reduction of interest was made to 3½ per

banks.

cent., subject, as before, to an obligatory reserve of one-fourth per cent., and to an optional one of another fourth, if needed.

Under the operation of this law very large sums were funded on depositors' account. The total number of banks in activity throughout France, at the end of 1855, was 368; that of their depositors, 893,750; and the aggregate of deposits, 272,182,542 francs (L.10,887,301). At the end of 1856 the banks had increased to 373; the depositors to 936,188; and the deposits to 275,342,913 francs (L.11,013,716). The population of France at this date was 35,781,628. The depositors, therefore, were as 1 in 38. Locally, the extremes are widely apart. In the metropolitan departments the depositors are 1 in 14; in the department of the Ariege they are 1 in 478. The average amount of deposits ranges between 504 francs (L.20) in the department of the Var, and 190 francs (L.7, 12s. 6d.) in the department of the Vosges. The accounts not exceeding 500 francs formed, in 1856, nearly 76½ per cent. of the whole number of accounts, and 37 per cent. of their sum-total; those from 500 to 1000 francs were 19¼ per cent. of the number, and 48 per cent. of the sum; the accounts of 1001 francs and upwards were as 4½ and 15 per cent. respectively. Of these only one-half per cent. in number, and 2¾ per cent. in amount, were legally exempt from compulsory conversion into stock.

The main points of organization and working may be briefly indicated thus:—(1.) *Formation*.—The initiative belongs to the municipal councils. An imperial decree establishes the new bank, on advice of the Council of State, and invests it with the power of receiving gifts and bequests. (2.) *Management*.—The board is chosen by the town-council, includes a certain proportion of councillors, and is renewable by thirds annually. (3.) *Expenses*.—The expenses are defrayed from reserve of interest; from municipal or other grants; from unclaimed or lapsed accounts; from interest of endowment funds, if any, and from surplus, if any. (4.) *Deposits*.—No sum less than a franc; no aggregation of sums exceeding L.12 in a week, or L.40 in the whole, are receivable from individual depositors (with certain exceptions in favour of soldiers and sailors). Friendly societies may invest up to L.320. (5.) *Interest*.—The usual net rate of interest is 3½ per cent.; in a few instances it is 3¾ per cent. (6.) *Investments*.—All savings banks (the three attached to *Monts-de-Piété* excepted) are bound to pay over, within twenty-four hours, to the public department called *Caisse des Dépôts*, all deposits received, retaining such a balance only as may be indispensable for the ordinary service until next receipt-day. (7.) *Withdrawals*.—Deposits are repayable at a fortnight's notice; they may be converted into stock free of charge; they may be transferred (in totality) to any other bank. (8.) *Unclaimed Accounts*.—Accounts neither claimed nor operated upon during thirty years pass in stock to the *Caisse des Dépôts*, and the savings bank is released from all responsibility in respect of them. (9.) *Superintendence*.—All savings banks in the departments are under the review of inspectors, who report both to the Minister of Finance and to the Minister of Agriculture and Commerce. An inspection and audit must be made at least once in every three months. Full accounts must be transmitted through the prefects to the Minister of Agriculture, &c., annually, and be officially distributed. The Paris bank is under the direct control of the Minister of Finance.¹

The Swiss banks date from 1787. The example set by Berne was followed by Geneva in 1789, and by Basel in 1793. But in all these cantons the operations of the first twenty or twenty-five years were inconsiderable. In 1815 or 1816, they began to be importantly developed. In 1835 there were in the whole of Switzerland 100 banks, with 65 branches, or dependent "receiving-houses," and 60,028 depositors, to whose credit there stood, in the aggregate, a sum of 11,513,712 Swiss *livres* (L.537,806). At the end of 1852 the banks had increased to 167, exclusive of branches; the depositors to 181,172; the deposits to 60,368,759 francs (L.2,414,745). In 1835 the Swiss population appears to have been 2,179,526. At the end of 1852, it was 2,392,000. The depositors, therefore, were, in 1835, as 1 in 36; in 1852, as 1 in 13. The average amount to each depositor was, in 1835, L.11, 10s. 7d.; in 1852, L.13, 6s. 6d. Finally, the aggregate deposits gave a sum of 6s. 6d. per head of population in 1835, and a sum of L.1 per head in 1852.

The management of the Swiss banks seems to be in some points lax, as compared with the prevalent systems of England and France, but the chief point of difference lies in the investments. Most of the cantons have no public debt worthy of mention. None of them, save Neuchâtel, permits a savings bank to invest money in foreign funds. Tessin and Glaris admit of government investments; but in all the other cantons the deposits are used in the way of loan upon mortgages, and in the discounting of mercantile bills. M. de Candolle, who, some years since, examined the Swiss system very elaborately, thus sums up his opinion as to its working:—"Throughout all the changes of government the savings banks have continued their useful career. Whatever the extent to which the government were compromised, private persons continued to find in those institutions a safe provision against all contingencies. Losses arising from the difficulty of recovering debts in disturbed times were met by the reserve funds previously created."²

The earliest savings banks of Germany were, as such, on a very narrow scale. Usually, they were directly connected with the administration of poor's funds. Often they were also loan banks. The Berlin bank, founded in 1818, gave an impulse to the improvement and diffusion of a better system, although it has itself suffered many modifications. Its original regulations guaranteed to the depositors interest at the rate of 4½ per cent. on ordinary deposits, a rate which was reduced to 3½ in 1827. In 1829, its aggregate deposits amounted to 1,229,413 thalers (L.179,289). In 1837, the amount of individual deposits was limited to 20 thalers (L.2, 18s. 4d.) in any one month, and to 300 (L.43, 15s.) in the whole. Eighteen months later, the existing bank was wound up, and a new one established in its place. At the close of the year 1839, the new bank held deposits amounting to 469,354 thalers (L.68,447). At the close of 1840, the amount was 576,528 thalers (L.84,077). Although seven years elapsed before the aggregate deposits in the new bank attained the sum held by the old bank in 1829, it appeared that investments by a plurality of accounts continued to be made by persons of a class different from that for which the bank was designed; and, to check this practice, another dissolution and re-organization was determined on in August 1850. The minimum deposit was now reduced to sixpence (5 silbergroschen), and the maximum deposits to L.1, 9s. 2d. (10

Savona. thalers) in any one month, and L.14, 11s. 8d. (100 thalers) in the whole. If any person shall open more accounts than one, the first account only bears interest. The deposits paid into the new bank during 1851 amounted to 351,765 thalers (L.51,299); the transfers from the old bank to 510,846 thalers (L.74,498); whilst the withdrawals were 104,384 thalers (L.15,222); leaving an aggregate sum to depositors' credit at the close of the year, of 901,289 thalers (L.131,438). At the close of 1852, this aggregate capital stood at 1,076,000 thalers (L.156,916), and belonged to 30,929 depositors. At the close of 1853, it had increased to 1,230,000 thalers (L.179,375), and the number of depositors to 34,842. On the 1st January 1855, the depositors were 35,590, and the total amount at their credit 1,249,000 thalers (L.182,145). On the 1st January 1857, the depositors were 40,700, and their aggregate deposits 1,424,000 thalers (L.207,666). At this date, therefore, the average sum possessed by each depositor was somewhat more than L.5, 2s., and the depositors were as 1 in 11 of the whole population of Berlin.

**Savings
banks of
Prussia
generally.**

Throughout the Prussian dominions there were founded, during the first decade from the beginning of the Berlin bank (1818-27), 31 savings banks; during the next (1828-37), 37; and during the third (1838-47), 123. Even in the disturbed years 1848 and 1849, 20 new banks came into being. The total number on the 1st January 1850 was 211, to which 4 more were added during the year. At its close, these 215 banks comprised 278,147 depositors, holding an aggregate deposit of 18,119,851 dollars, or L.2,642,464. The relative proportion of banks to population varied from 1 in 502,984 in the circle of Dusseldorf, to 1 in 25,207 in the circle of Ainsberg; the mean proportion for the whole of the kingdom being 1 in 70,091, and that of depositors 1 in 59. The average amount held by each depositor throughout the kingdom was, in 1849, L.9, 3s. 9d.; in 1850, L.10, 4s. 2d. The rates of interest varied considerably. In 23 banks it was 2½ per cent.; in 35 other banks, 3 per cent.; in about 150 others, 3½ per cent.; whilst in 5 banks it ranged from 4 to 5 per cent.

In some banks the rate varies with the amount of the Savonarola deposit.

In the German provinces of Austria, the proportion of Other States of depositors to population was, according to the latest returns, to which we have access, 1 in 49; in Hanover, 1 in 42; Germany, in Bavaria, 1 in 18; in Saxony, 1 in 16; in Frankfurt-on-the-Maine, 1 in 11½; in Hamburg, 1 in 7½; in Altona, 1 in 26. In Austria, the average aggregate deposit was, to each depositor, L.19, 6s. 9d.; and to each inhabitant 7s. 10d. In Bavaria, it was, respectively, L.5, 18s., and (nearly) 6s. 8d.; in Hanover, L.9, 10s., and 4s. 5d. The savings bank statistics of the last-named country are remarkable for the rapid growth they indicate of the aggregate deposits since 1848.¹

In most of those parts of Europe which are yet unnoticed, the development of savings banks is comparatively recent and immature. This cannot, however, be said of Italy. In Piedmont and in Lombardy, for example, they have long formed an important feature of the economical condition of the country. But the institution which in Italy is called *Cassa di risparmio* differs materially from those which elsewhere bear that name. Its regulations attract the investments of persons of a much higher class than those for whom savings banks are usually intended. There are some exceptions to this rule; but, on the average, it has been estimated that hardly more than one-fourth of the deposits in Italian savings banks are held by depositors who would be ranked, socially, with those of the United Kingdom, of France, or of Germany. In Spain and Portugal, these institutions are yet in the cradle. In Russia, they have scarcely advanced beyond St Petersburg and Moscow. A wider intercommunication of the progress and results of the savings banks of different countries would doubtless give an increased impulse to the diffusion of establishments which have proved themselves to be powerful agents in the social elevation of the masses, even when very imperfectly organized and worked. Taken as a whole, their past history warrants high anticipations of the future. (E. E.)

SAVONA, a town of the kingdom of Sardinia, capital of a division of the same name, on the shore of the Mediterranean, 25 miles S.W. of Genoa. It stands at the foot of a hill to the W., and is partially surrounded by ancient walls, and defended by a citadel of no great strength. The town itself has some good houses; but, for the most part, it is not well built, and has extremely narrow streets. There is a fine cathedral, built in 1604, when the former one was removed to make room for the citadel. Many valuable works of art adorn the present edifice. The Sistine chapel was erected by Pope Sixtus IV. as a burial-place for his family. The Dominican church contains paintings by Albert Durer and Antonio Semini; and the church of San Giacomo contains the tomb of Chiabrera, a celebrated lyric poet, and a native of this place. Savona has several convents, an episcopal seminary, two colleges, hospitals, and other charitable institutions. The harbour, which was once very good, was partially filled up by the Genoese, out of jealousy of the commerce of Savona. It is still safe, though only accessible to small vessels. A considerable trade is carried on in silk, wine, and fruit. Savona is the seat of a bishop, public offices, and law courts, and many of the nobility have fine palaces in the town. Pop. 17,000.

The administrative division of Savona comprises the three provinces of Acqui, Savona, and Albenga, the first

lying inland, and the other two along the coast. The principal mountains are the Apennines, which have in this division a considerably lower altitude than in the other parts of the range. They stretch nearly parallel to the coast, at no great distance from it, and send down numerous small streams and torrents to the sea. The northern part of Savona is occupied with ramifications of the Apennines, and watered by many small affluents of the Po. The whole division is very fertile, especially the valley of Albenga, producing corn, wine, oil, fruit, hemp, &c. The division is subdivided as follows:—

Province.	Area in Square Miles.	Pop. (1827)
Savona.....	311	79,643
Acqui	444	106,819
Albenga.....	263	58,485
Total.....	1018	244,947

SAVONAROLA, GIROLAMO, a famous Italian monk, was born at Ferrara in 1452, being descended of a noble family. At the age of twenty-two he assumed the habit of a Dominican friar, without the knowledge of his parents, and distinguished himself in that order by his piety and ability as a preacher. Florence was the theatre where he chose to appear, and where he preached, confessed, and wrote. He had address enough to place himself at the head of the faction which opposed the family of the Medici. He explained the Apocalypse, and there found a prophecy

¹ Art "Sparkassen," in the Supplement to Meyer's *Conversations-Lexicon*, v. 882-889; De Boudard, *Institutions de prévoyance*, &c., ut supra, 30-33; Appendices to the Paris Reports.

Savoy. which foretold the destruction of his opponents. He predicted a renovation of the church, and declaimed with much severity against the clergy and the court of Rome. Alexander VI. excommunicated him, and prohibited him from preaching. He derided the anathemas of the Pope; yet he forbore for some time from preaching, and then resumed his employment with more applause than before. The Pope and the Medici family then thought of attacking him with his own weapons. Savonarola having posted up a thesis as a subject of disputation, a Franciscan, at their instigation, offered to prove it heretical. The Franciscan was seconded by his brother friars, and Savonarola by his; and thus the two orders were at open war with each other. To settle the dispute, and to convince their antagonists of the superior sanctity of Savonarola, one of the Dominicans offered to walk through a fire; and in order to prove his wickedness, a Franciscan agreed to the same experiment. The multitude, eager to witness so extraordinary a spectacle, urged both parties to come to a decision; and the magistrates were constrained to give their consent. Accordingly, Saturday the 7th of April 1498 being fixed for the trial, the Dominican pretended he could not enter the flames without the host in his hand. This the magistrates obstinately refused to allow; and the Dominican's fortitude was not put to the test. The Franciscans incited the multitude against their opponents, who accordingly assaulted their monastery, broke open the gates, which were shut against them, and entered by force. Upon this, the magistrates thought it necessary to bring Savonarola to trial as an impostor. He was put to the torture and examined, and the answers which he gave fully evinced that he was both a cheat and a fanatic. He boasted of having frequent conversations with God, and he found his brother friars credulous enough to believe him. One of the Dominicans who had shared in his sufferings, affirmed that he saw the Holy Ghost in the shape of a dove, with feathers of gold and silver, twice in one day alight on the shoulder of Savonarola and peck his ear; and he pretended also that he had violent combats with demons. John Francis Picus, count of Mirandola, who wrote his life, assures us that the devils which infested the convent of the Dominicans trembled at the sight of Friar Jerome, and that out of vexation they always suppressed some letters of his name in pronouncing it. At length the Pope, Alexander VI., sent the chief of the Dominicans, with Bishop Romolino, to degrade him from holy orders, and to deliver him up to the secular judges, with his two fanatical associates. They were condemned to be hanged and burned on the 23d of May 1498. According to some accounts, Savonarola submitted to the execution of the sentence with great firmness and devotion, and without uttering a word respecting his guilt or his innocence; but others say his firmness failed him, and he acknowledged the falsehood of his pretensions to supernatural powers. He was in the forty-sixth year of his age. His works have been published at Leyden in six vols. 12mo.

SAVOY (Ital. *Savoja*, Fr. *Savoie*), **Ducry** or, a portion of the kingdom of Sardinia, lying between N. Lat. 45. 4. and 46. 24., E. Long. 5. 37. and 7., bounded on the N. and N.E. by Switzerland, E. and S.E. by Piedmont, S.W. and W. by France. Length from N. to S. 92 miles, breadth 66; area 4197 square miles. Geographically, Savoy belongs rather to Switzerland than to Italy; as it is separated from the latter country by the Graian and Pennine Alps, the loftiest chains of those mountains, while all the rivers that water the country discharge their waters ultimately or immediately into the Rhone. From Switzerland it is only separated by the lake of Geneva; from France on the W. by the Rhone, and on the S.W. by the Maurienne Alps, an off-set of the Cottian Alps, extending westwards from Mont Cenis. The country thus inclosed is one of the most mountainous in Europe; for the moun-

Savoy. tains which border it send out numerous ramifications, which make the whole surface a continual series of lofty elevations and deep valleys. The Graian Alps extend from Mont Cenis to Mont Blanc, forming a curve with the convex side towards Piedmont. They contain not only the highest peaks, but the most gigantic glaciers and the wildest passes that are to be found in the whole of the Alps. The summits of Mont Iséran and the Little St Bernard, the glaciers of Mont Iséran, of Clou, of Ruitors, and the passes of Galesia, Galetta, and Little St Bernard, are among the most important. The mountains which border upon Savoy consist, as we have seen, of the main ridge, and one large ramification of the Alps; those which occupy the centre of the country, consist of three important branches of the same great mountain system. Furthest south, the mountains of La Vanoise diverge from the main ridge at Mont Iséran, and occupy the whole region between the Isère and its affluent the Arc, curving to the southwards, along the banks of the latter river, and forming by their off-sets to the north the valleys of the upper tributaries of the Isère. From the Little St Bernard extends another great branch, called the Alps of Savoy, which covers with its ramifications all the country between the Arve, the Rhone, and the Isère. This chain extends for some distance to the W. and N.W., till at a point called Grande Crête, S.W. of Salanches, it divides into two branches, the one continuing a N.W. course, till it terminates at the Rhone opposite the end of the Jura on the French side; the other and more important branch turns to the S.W., and, after a zigzag course along the lake of Annecy, skirts the Isère, and terminates in the Grande Chartreuse in France. The third branch, called the Alps of Savoy and Valais, diverges from the Pennine Alps at Mont Crapillon, and stretches N.W. to the lake of Geneva, occupying, with its offshoots, the country between that lake, the Arve, and the Rhone. This is the most northerly of the mountain-chains that traverse Savoy. The principal valleys in the country are those traversed by the rivers already mentioned; but there are innumerable others, down which flow streams of less size and importance. There are only two lakes of any size in Savoy, those of Bourget and Annecy, neither of which are to be compared with that of Geneva. The former discharges its waters by a canal into the Rhone, the latter into the Fier, an affluent of that river. From the natural character of the surface, the amount of arable land in Savoy is necessarily very limited; but the insufficiency of the grain raised is in a large measure supplied by chestnuts, which form an important article of food for the lower classes. Vines are cultivated in a few places, in the lower valleys and slopes. Cattle and dairy produce, however, form the principal riches of the country, along with the timber which clothes the lower portions of many of the mountains. Some minerals are found, but not anywhere in large quantities. The only articles manufactured are coarse woollen stuffs, leather, and hardware. The produce of the country is exported; and there is a considerable transit trade carried on through Savoy between France and Italy, chiefly by way of Mont Cenis. Savoy forms in the kingdom of Sardinia the divisions of Annecy and Chambéry, and is subdivided into provinces as follows:—

Provinces.	Area in Sq. Miles.	Pop. (1867.)
Annecy	620	103,763
Faucigny	786	103,986
Chablais	326	60,193
Division of Annecy.....	1722	267,942
Chambéry	633	155,916
Upper Savoy	346	49,276
Maurienne.....	798	64,063
Tarentaise	698	44,636
Division of Chambéry	2475	313,891
Total of Savoy.....	4197	681,833

Saw.

The leading events in the history of Savoy are mentioned in the Article *SARDINIA*.

SAW, a well-known instrument for cutting asunder.

The saw is of unknown antiquity, being figured on the ancient monuments of Egypt and Babylon. It is probable that saws were first made of copper, hardened by the admixture of a little tin. But after the invention of steel that substance has come, almost exclusively, to be used in their manufacture.

The common saw consists of a steel plate, on the edge of which teeth are formed: these teeth, when drawn over a piece of timber, act as a succession of chisels, and so make a cut or saw-draft. When the teeth are left in the plane of the plate, and when the saw has entered a little way into the timber, the sides of the cut come to rub against the plate, thus causing a friction, which soon arrests the operation. There are two ways in which this evil is remedied: the one is by making the plate thin towards the back, as in the key-hole saw; the other is by bending some of the teeth to the one side, some to the other side of the saw-plate, so that they make a draft considerably wider than the thickness of the plate. This bending is called the *set* of the saw. It is obvious that the best method is to set the teeth alternately to the right and to the left; but in the East, where ancient practices are scrupulously adhered to, the teeth of the large saws are bent aside in groups of perhaps a dozen each. The quantity of set is regulated by the nature of the material to be cut; for soft and fibrous woods, more set is needed than for hard woods. Since the labour of cutting and the waste of material are increased by the set and consequent width of the saw-draft, it is an object to give to the saw as little set as possible, and the friction is reduced in some cases by bending the halves of the log asunder by means of wedges; in other cases by the use of soap, tallow, or oil, to lubricate the sides of the saw.

Although it seems to be a very simple affair, the sharpening and setting of a saw require considerable skill of hand and accuracy of eye, for if any one of the teeth project, either edgewise or sidewise, beyond the general line, it takes hold of the wood and renders the sawing harsh and difficult. The form of the tooth, also, is a matter of some importance. When the teeth of the saw become blunted by use, they are sharpened by means of a file, which is three-sided, or, as the workmen call it, *three square*. This is the most economical form of saw-file, because all its edges and faces are equally available. The angles of a four-sided file are too great, and an isosceles three-sided one would, although the angle might suit better for some purposes, have only one or at most two edges available. Hence for common use we are compelled to adopt the ordinary equilateral three-sided file, and, in consequence, the angle of the saw-tooth is sixty degrees.

Let ABCDEFGHI represent part of the edge of a saw, of which the notches BCD, DEF, &c., have been made by a three-cornered file; then if the sides AB, BC of the tooth be equally inclined (as in fig. 1) to the general line of

Fig. 1.

the edge, the instrument acts equally well in either direction; but in this case the teeth can hardly be said to cut, they only scrape away the material. Saws of this kind are used in cross-cutting, being worked by two men—one at each end; but as the teeth are large, they are punched

out at the fly-press, and are made deeper than an equilateral trigon.

Saw.

In order that the tooth have a proper cutting edge, the front BC must be (as in fig. 2) at least perpendicular to the

Fig. 2.

line of the cut, and therefore the back AB must, at most, make an angle of thirty degrees with that line. For many kinds of timber it would be advantageous to have the front of the tooth leaning forward (as in fig. 3), but this form

Fig. 3.

allows little room for the saw-dust, and is accompanied by a tendency to drag the tool in upon the wood, thus causing the strain to be too great for the hand-saw; nevertheless, a slight inclination forward is, in certain cases, advantageous.

When a saw is to be sharpened, it is convenient to draw the file gently along the tops of the teeth, and so reduce them all to an even line: we then take care, in filing out the notches, to do no more than remove the bright surfaces, thus exposed: by this precaution we secure the even lining of the teeth edgewise. The setting is a more difficult affair; it is done sometimes by the hammer and sometimes by a saw-key. When the hammer is to be used, the saw is laid upon an iron plate, so that the teeth may project over its chamfered edge. Each alternate tooth is lightly struck by a hammer, the weight of which must be adapted to the size of the teeth; the saw is turned over and the intermediate teeth struck on the other side; the lining is examined by the eye, and any errors are corrected. The setting key is a piece of steel, having notches of various widths cut in it to suit the different thicknesses of saw-plates; by means of these notches the teeth can be bent to the required degree. It has been proposed to fix a stop upon the set-key, which stop, coming against the plate of the saw, may regulate the degree of bending; but the elasticity of the steel carries the tooth back somewhat from the extreme angle of flexure, so that the residual set depends partly upon the temper of the steel; thus, after all, the eye becomes the ultimate judge.

In filing the teeth we must pay attention to the set; thus, if the tooth B be bent to the left, the left edge of the face BC should be made acute, as should also the right edge of DE. Hence the alternate spaces BCD, FGH, &c., should be filed out from the right, and the intermediate spaces, DEF, &c., from the left, the point of the file being, in both cases, inclined a little forward.

The saw-plate should be left as hard as is consistent with its being bent; if it be too hard, the teeth are apt to break off in being set; if it be soft, the teeth are rapidly blunted.

To the one end of the saw-plate a handle is fixed, by means of which it can be moved backwards and forwards. In this country it is usual to make the saw cut when being thrust forward; in other words, the teeth look from the handle; but the modern artificers in Greece and other eastern countries make the cut in pulling, as also did the ancients; the teeth look towards the hand. There is something to be said in favour of and against both methods. The cut, in pushing, enables us to apply greater muscular energy, and the entrance of the saw being towards the eye, we can readily follow the line; but, on the other hand, any

Saw. sudden jerk or unskilful holding of the tool is apt to bend or buckle it. The cut, in pulling, again, tends to straighten the saw, so that a very thin plate may be used, requiring less labour and causing less waste of material; it is peculiarly suitable for workmen, who hold by their toes; but then the saw-dust is heaped upon the line and has often to be swept or blown away.

The advantages of both of these methods are obtained by stretching the saw tightly in a frame; and even more than these advantages, because we can use saw-webs much narrower and much thinner than when the plate is to be held by one end. The narrowness of the web allows it to be turned considerably within the saw-cut, so that it may follow a curved line, whereas the hand-saw is almost restricted to a straight cut. Saw-webs for frames are made of great minuteness, the breadth even so little as the fiftieth of an inch, and the width of the draft not perhaps the third of that. These hair saws are extensively used for inlaying woods, ivory, and shell, as they can follow the most delicate outlines; they are also used by gold and silver smiths, on account of the smallness of the waste which they occasion.

Saws for cutting bone, ivory, or brass, require very little set; it is sufficient to have the web somewhat thinner toward the back. For these saws the steel is left pretty hard, as much so, indeed, as is consistent with their being readily filed. The preparation of saws for cutting iron or steel is a matter of considerable nicety; they must be very hard in order to resist the oxides and silicates which are to be found in the most carefully prepared iron, and yet they must be so soft as to be filed, although with difficulty; hence really good *iron-webs*, as they are called, are somewhat scarce.

The teeth of large saws, such as those used in the saw-pit or in the saw-mill, are cut out by means of a fly-press, in which a punch and socket exactly of the form of the notch are fixed. The edges are afterwards dressed by the file. Hence they are shaped more in accordance with the principles of cutting tools. The front of the tooth is hooked forward by even so much as forty or forty-five degrees, and the back is relieved only by an angle of eight or ten degrees. But if lines with these inclinations were continued to meet each other (as shown in fig. 4), there would be no

Fig. 4.

room left for the dust, and the saw would be immediately clogged; wherefore a large hollow space is scooped out (as shown in fig. 5), giving to the teeth a very formidable ap-

Fig. 5.

pearance. These saws are sharpened by filing the parts marked A B; and when the teeth become too shallow, they are again deepened at the fly-press, or, if no fly-press be at hand, by means of round files applied to the hollows.

Circular Saws.—The straight saw must necessarily have a reciprocating motion; but when teeth are formed on the edge of a circular disc, the motion is continued in one direction, and great velocity can be obtained. Circular saws are now so very generally used that every one at all interested in mechanical affairs must be familiar with their general appearance and mode of operation.

Part A B C of the circular disc projects through a slit

Saw.

Fig. 6.

in the table D E. The piece of timber to be cut is laid on the table, and carefully brought up to the descending part of the saw at C; the saw being made to revolve with great velocity. When slices of a given thickness have to be cut off a log, a fence is placed on the table at E, parallel to and at the proper distance from the plane of the saw: the log is laid against this fence, and is pushed forward either by hand or by help of the machinery.

This is a dangerous instrument, not to be approached without caution, and, above all, not to be tampered with by foolish meddlers. If a lump of wood were presented at the rising part A, it would be caught by the hooked teeth, hurried over towards C and thrown off, to the great danger of those around, as well as of the saw itself.

Small circular saws have their teeth shaped by the triangular file: the fronts of them should point to the centre.

Veneer Saws.—The veneer saw is contrived for the purpose of cutting finely variegated woods into thin broad slices. The veneer varies from a 24th to a 30th of an inch in thickness, so that if the saw-draft be one 24th of an inch wide, half of the timber is cut into saw-dust. Now, the wood of which veneers are made is almost always very valuable, and hence it is of great importance to have the saw extremely thin.

The body of the veneer-saw consists of a lenticular piece of cast-iron, having the meniscus form—that is, hollow on the one side and round on the other. A section of it is given in fig. 7. The hollow part at B is made sufficiently

Fig. 7.

deep to receive the bush which carries one end of the axle, and which rests on an overhanging support. Part of the edge AC is turned flat, and to this flat part the steel saw is screwed in segments—the screw heads being countersunk so as not to project beyond the outer face of the segment. These segments are ground away toward the edge, as shown in the section K L, and are thus made to form the rim of a very thin circular saw. The grinding and adjustment of these segments require great care.

The log to be cut into veneer is secured to a frame F, which can be moved by screws G, transversely upon a carriage E. This carriage moves upon two long iron slides or rails, laid exactly at right angles to the axis of the saw

Saw-Mill.

The screws G serve to regulate the thickness of the successive slices. When the log is advanced upon the saw in the direction of the arrow, the thin veneer, which has been separated at the edge I, is bent away over the back of the saw, either by the workman's hand or by a small guide set up for the purpose. When one cut has been made, the carriage is returned, the log moved transversely by means of the screws G, and then advanced again to meet the saw.

Veneer saws are made from 5 to 20 feet in diameter, according to the breadths of the logs which they may have to cut, and from 12 to 18 slices are made in each inch of thickness.

Cylindric Saws.—The cylindric saw is formed by making teeth on the end of a thin tube of steel, and are useful for cutting circular holes in valuable material, as ivory or tortoise-shell, without destroying the interior part. As there is no way for the escape of the cuttings, they have to be withdrawn now and then from the cut.

Ribbon Saws.—The latest novelty in the formation of saws is the *ribbon-saw*, which is formed of a long, thin web of steel united at the two ends, or, it may be, of a continuous web rolled from a steel ring. This web, having teeth cut in one of its edges, is passed over two large pulleys, which are put in rapid motion; the descending free part of the web acts as a straight frame-saw, with this difference, that the motion is continuous, and that the action is very rapid.

Lapidary's Saws.—For cutting slate and other soft stones saws of steel are used; but for harder stones, webs of soft iron or copper, primed with sand and water, are employed. It is by means of such a tool that marble is sawn into slabs. When the plate of iron, stretched in a proper frame, is moved backwards and forwards upon the stone, the sharp fragments of the sand imbed themselves in it and act as saw-teeth, but they are so soon rubbed out that the action partakes greatly of the nature of grinding.

For very hard stones emery and corundum powders are used, and for extremely hard stones pounded diamond is employed; the circular form of the saw being generally adopted. The diamond-wheel is truly a saw, for the fragments of diamond stick with great pertinacity into the iron, and act exactly as saw-teeth.

Lapidary's saws were well known to the ancients: some of the sarcophagi retain the marks of the tools by which they were scooped out. A tube of iron or of copper, primed with sand and water, was turned round upon the stone, and thus caused to make a cylindric cut; when this cut was sufficiently deep, the central cylinder of stone was broken over. Another and another hole of this kind was made until the required hollow was roughly formed; the intermediate triangular pieces were broken away, and the inside of the chest was then finished by the chisel and smoothing tools. This is exactly the process which is followed at the present day in doing the like kind of work. (E. S.)

SAW-MILL, a place in which sawing is carried on by help of wind, water, or steam power.

The principal part of the saw-mill is the frame-saw used for cutting up logs, represented in figures 8 and 9. It consists of a frame AA moving between two vertical cheeks. In this frame the saw-webs are stretched according to the nature of the work to be done; these must be fitted truly parallel to the line of motion, and at such distances from each other as to produce planks of the desired thickness.

This frame AA is moved upwards and downwards by means of a crank attached to the machinery, and acting through the connecting rod B; the saws cut while descending. The log to be operated on is fixed in a long frame CC, which is brought forward by means of a pinion fixed to the axis of the ratchet-wheel D. The *feed*, as it is called, is obtained in this way; the end E of the lever EFG is attached to the saw-frame, so as to oscillate with it, thus

causing the arm FG to oscillate also; this arm FG has a row of holes in it for attaching the hook H, which, acting on the ratchet-wheel, brings it round by the distance of one or more teeth at each descent of the saw; the number

Sawunt
Warree.

FIG. 8.

of teeth and consequent feed being regulated by the effective length of the arm FG.

The log passes over a support K as close to the saws as possible, and is kept in its place by fences or rollers LL, acting on its sides; it is also prevented from rising by two struts, M and N, hanging from the frame-work.

Circular, veneer, and ribbon saws belong naturally

FIG. 9.

to the saw-mill; they have been sufficiently described in the preceding article.

In the saw-mill we often find other kinds of work carried on. Flooring deals and lining boards, after having been roughly shaped by the saw, are dressed to the required breadth and thickness, planed smooth, feathered and grooved on a machine in which planes, saws, and adzes are combined. Battens, too, have their tenons and mortices dressed by appropriate machinery, and the naves of cart-wheels have their spoke-holes neatly cut out by a combination of augers and chisels; but these are additions to the saw-mill proper. (E. S.)

SAWUNT WARREE, a native state of India, under the political management of the British, in the presidency of Bombay, lying between N. Lat. 15. 38. and 16. 15., E. Long. 73. 40. and 74. 22.; bounded on the N. and W. by the British collectorate of Rutnageriah, S. by the Portu-

Saxe.

guese territory of Goa, and E. by the native state of Kolapoor. Length from N. to S. 50 miles; greatest breadth about 30; area, 800 square miles. It is an exceedingly rugged and mountainous country, consisting mainly of a ship of land on the summit and western declivity of the Ghauts, and in some places extending over the ridge into the Deccan. The scenery is very remarkable and romantic; huge masses of mountain rise to the height of 3000 or 4000 feet, and, except a few patches of bare black rock, are entirely covered with forests of teak and other trees. Numerous rivers, large and small, flow down from the mountains and intersect the jungles which occupy the lower ground. The soil thus watered gives rise to a luxuriant vegetation, but the superior kinds of crops cannot be raised, such as cotton, sugar, &c.; and the staple produce of the country is wheat, rice, pulse of various kinds, and esculent vegetables. The climate is moist; and the rain which falls among the mountains during the monsoons are probably more excessive than in any other part of the world. The principal articles manufactured here are gold and silver embroidery, saddlery, guns, swords, and other arms. Cocoanuts are the most important article of exportation. The annual revenue of Sawunt Warree is about £20,000, and the expenditure somewhat less. The military force consists of a local corps of infantry, under European officers, amounting to 611 men. The city and territory of Warree derived the title of Sawunt from a Mahratta family of that name, who governed them as chieftain under the monarchs of Beejapoor. In 1659 the reigning chieftain formed an alliance with Sevajee, and though this was soon broken, the Mahratta chief in 1662 conquered the country, and afterwards restored the Sawunt family to the position of dependent chieftains. The first treaty between Sawunt Warree and the British took place in 1730, and had for its object to suppress the piracies of the Angria family in the island of Kolabah. But the chieftains of Sawunt Warree being themselves addicted to piracy, drew upon them the hostility of the British in 1765. A series of wars, treaties, and negotiations ensued, which ended in the subjugation of the state in 1819 by a British force. The sea-coast was then ceded to the British, and the native government restored. Rebellions were raised against the chiefs in 1828, 1832, and 1838. On the two former occasions the British restored their authority; on the last it was deemed necessary to effect a change, and the country was placed under British management, as it has since remained. The most important event that has since occurred was the dangerous rebellion which began in the autumn of 1844, and was put down after some months of hard fighting by Lieutenant-Colonel Outram in the beginning of the following year. Since then peace and tranquillity have reigned, suttee has been abolished, and many other improvements introduced. Pop. 120,000.

SAXE, MAURICE, COUNT OF, was born on the 19th of October 1696. He was the natural son of Frederick Augustus II., Elector of Saxony and King of Poland, and of the Countess of König-märck, a Swedish lady, celebrated both for her wit and her beauty. He was educated along with Frederick Augustus, the electoral prince, afterwards King of Poland. His infancy announced the future warrior. Nothing could prevail on him to apply to his studies but the promise of being allowed, after he had finished his task, to mount on horseback, or exercise himself in arms. He served his first campaign in the army commanded by Prince Eugene and the Duke of Marlborough, when only twelve years old. He signalized himself at the sieges of Tournay and Mons, and particularly at the battle of Malplaquet. In the evening of that memorable day, he was heard to say, "I'm content with my day's work." Next year the young count accompanied the King of Poland to the siege of Stralsund, the strongest place in Pomerania, and displayed the

Saxe.

greatest intrepidity, swimming across the river in sight of the enemy, with a pistol in his hand. His valour shone no less conspicuously on the bloody day of Gadebusch, where he commanded a regiment of cavalry. He had a horse killed under him, after he had three times rallied his regiment, and led them to the charge. Soon after that campaign his mother prevailed on him to marry the Countess of Lubin, a lady both rich and beautiful. This union lasted but a short time. In 1721 the count procured a dissolution of the marriage; a step of which he afterwards repented. The countess left him with regret; but this did not prevent her from marrying soon afterwards. The Count of Saxe was too fond of variety to submit to the duties which marriage imposes. In the midst, however, of the pleasures in which he sometimes indulged, he never lost sight of his profession. He carried along with him wherever he went a library of military books; and even when he seemed most occupied with his pleasures, he never failed to spend an hour or two in private study. In 1717 he went to Hungary, where the emperor had an army of 15,000 men commanded by Prince Eugene. Count Saxe was present at the siege of Belgrade, and at a battle which the prince gained over the Turks. On his return to Poland in 1718, he was made a knight of the Golden Eagle. The wars in Europe being concluded by the treaties of Utrecht and Passarowitz, Count Saxe went to France. He had always professed a partiality for that country. French, indeed, was the only foreign language which during his infancy he was willing to learn. He spent his whole time during the peace in studying mathematics, fortification, and mechanics, sciences which exactly suited his genius. The mode of exercising troops had taken his attention when very young. At sixteen he invented a new exercise, which was taught in Saxony with the greatest success. Having obtained a regiment in France in 1722, he formed it himself according to his new plan. From that moment the Chevalier Polard, an excellent judge of military talents, predicted that he would be a great man. His personal size was extraordinary, and he is said to have possessed great bodily strength. In 1726 the states of Courland chose him for their sovereign, but both Poland and Russia rose in arms to oppose the election. The Czarina wished to bestow the duchy on Mentschikoff, a happy adventurer, who from a pastry-cook's boy became a general and a prince. Mentschikoff sent eight hundred Russians to Milan, where they besieged the newly chosen duke in his palace. Count Saxe, who had only sixty men, defended himself with astonishing intrepidity. The siege was raised, and the Russians were obliged to retreat. Soon afterwards he retired to Usmaiz, and prepared to defend his people against the two hostile nations. Here he remained with only three hundred men, until the Russian general approached to force his retreat, at the head of four thousand. That general invited the count to a conference, during which he intended to surprise him, and take him prisoner. The count, informed of the plot, reproached him for his baseness, and broke up the conference. About this time he wrote to France for men and money. Mademoiselle le Couvreur, a celebrated actress, pawned her jewels and plate, and sent him the sum of forty thousand livres. This actress had formed his mind for the fine arts. She had made him read the greater part of the French poets, and given him a taste for the theatre, which he retained even in the camp. The count, unable to defend himself against Russia and Poland, was obliged, in the year 1729, to leave his new dominions, and retire into France. It is said that Anne Ivanowna, Duchess-dowager of Courland, and second daughter of the Czar Iwan Alexiowitz, had given him hopes of marriage, and abandoned him at that time because she despaired of fixing his wavering passion. This inconstancy lost him not only Courland, but the throne of Russia itself, which

Saxe.

that princess afterwards filled. Count Saxe, thus stripped of his territories, devoted himself for some time to the study of mathematics. He composed also, in thirteen nights, and during the intervals of an ague, *Mes Réveries*, which he afterwards corrected. This book is written in an incorrect but forcible style; it is full of remarks both new and profound, and is equally useful to the soldier and the general.

The death of the King of Poland, his father, in 1733, kindled a new war in Europe. His brother, the Elector of Saxony, offered him the command of all his forces; but he preferred the French service, and repaired to Marshal Berwick's army, which was encamped on the Rhine. "Count," said that general, who was preparing to attack the enemy's entrenchments at Etlinghen, "I was going to send for three thousand men, but your arrival is of more value than theirs." When the attack began, the count, at the head of a regiment of grenadiers, forced the enemy's lines, and by his bravery decided the victory. He behaved with no less intrepidity at the siege of Philipsburg. For these services he was, in 1734, rewarded with the rank of lieutenant-general. Peace was concluded in 1736; but the death of Charles VI., the Emperor of Germany, almost immediately kindled a new war. Prague was besieged by the Count of Saxe in 1741, near the end of November, and was taken the same month by assault. The conquest of Egra followed that of Prague. It was taken a few days after the trenches were opened. This success gave so much joy to the Emperor Charles VII., that he wrote with his own hands a congratulatory letter to the conqueror. In 1744 he was made marshal of France, and commanded a part of the French army in Flanders. During that campaign he displayed the greatest military conduct. Though the enemy was superior in number, he observed their motions so skilfully that they could do nothing. In January 1745, an alliance was concluded at Warsaw between the Queen of Hungary, the King of England, and the states of Holland. The ambassador of the states-general, meeting Marshal Saxe one day at Versailles, asked his opinion of that treaty. "I think," said he, "that if the king my master would give me an unlimited commission, I would read the original at the Hague before the end of the year." This answer was not a bravado; the marshal was capable of performing it. He went soon afterwards, though exceedingly ill, to take the command of the French army in the Low Countries. A gentleman, seeing the feeble condition in which he left Paris, asked him how he could in that situation undertake so great an enterprise. "The question," replied he, "is not about living, but setting out." Soon after the opening of the campaign, the battle of Fontenoy was fought. Marshal Saxe was at the point of death, yet he caused himself to be put into a litter, and carried round all the posts. During the action he mounted on horseback, though he was so very weak that his attendants dreaded every moment to see him expire. The victory of Fontenoy, which was owing entirely to his vigilance and capacity, was followed by the reduction of Tournay, Bruges, Ghent, Oudenard, Ostend, Ath, and Brussels. This last city was taken on the 28th of February 1746; and very soon afterwards the king sent to the marshal a letter of naturalization, conceived in the most flattering terms. The succeeding campaigns gained him additional honours. After the victory of Raucoux, which he gained on the 11th of October 1746, the King of France made him a present of six pieces of cannon. He was, on the 12th of January of the following year, created marshal of all the French armies, and, in 1748, commander-general of all those parts of the Netherlands which were lately conquered. Holland now began to tremble for her safety. Maestricht and Bergen-op-Zoom had already fallen, and nothing but misfortunes seemed to attend the further prosecution of the war. The states-general, therefore, offered

terms of peace, which were accepted, and a treaty concluded on the 18th of October 1748.

Marshal Saxe retired to Chambord, a country-seat which the King of France had given him. Some time afterwards he went to Berlin, where the King of Prussia received him as Alexander would have received Cæsar. On his return to France, he spent his time among men of learning, artists, and philosophers. He died of a fever, on the 30th of November 1750, at the age of fifty-four.

The best edition of his *Réveries* was printed at Paris, 1757, in five volumes 4to. It was compared with the greatest attention with the original manuscript in the king's library. It is accompanied with many designs exactly engraved, and a life of the author written in the panegyric style. There is an English translation of it, by Sir William Fawcett, 1757.

SAXE-ALTENBURG (Germ. *Sachsen-Altenburg*), a small duchy of Germany, consisting of two separate parts, divided from one another by portions of Reuss and Saxe-Weimar, and lying between N. Lat. 50. 43. and 51. 10.; E. Long. 10. 50. and 11. 53.; the eastern part being bounded on the N.E. and S. by the kingdom of Saxony, W. by Reuss and Saxe-Weimar; and the western, W. and N. by Saxe-Weimar and Prussia; E. and S. by Reuss, Saxe-Weimar, Saxe-Meiningen, and Schwartzburg. These two portions form the two circles of the duchy; the former that of Altenburg, and the latter that of Saal-Eisenberg; and their area and population are as follows:—

	Sq. miles.	Pop. (1857)
Altenburg	214	87,091
Saal-Eisenberg	278	46,502
Total.....	522	133,593

The eastern portion, lying on the northern slope of the Saxon mountains, has a smooth or gently undulating surface, and a very fertile soil; the western portion is less fertile, but abounds in mountains and forests, lying partly among the Saxon and partly among the Thuringian hills. Dollenstein, near Kahla, the loftiest point in the country, does not exceed 1000 feet in height. The principal river in this part is the Saale, an affluent of the Elbe, which receives here the Orla and the Roda; the eastern part of the duchy being watered by the Pleisse, which afterwards unites with the Saale. The climate is temperate, pleasant, and healthy. There are mineral springs at Ronneburg and other places. With the exception of minerals, which are few, Saxe-Altenburg has all the ordinary natural productions. Agriculture is, especially in the eastern part, carried on with diligence and success. The quantity of arable land in the country is 213,982 acres; of wood, 66,838; of meadows, 24,200; of gardens, 10,822; and of pasture land, 7030. The quantity of corn raised is more than sufficient for domestic consumption. Pulse, potatoes, and other vegetables, are also grown. Cattle are raised in large numbers, and of a good breed; the horses and sheep are also excellent. The duchy contains 6200 horses; 56,000 horned cattle; 75,000 sheep; and 25,000 pigs. Deer and wild boars are found in the woods, and fish in the streams. Coal, building-stone, and porcelain-clay, are the most important minerals. Manufactures are not very extensively carried on in Altenburg: woollen, cotton, and linen cloth; wooden articles; beer, brandy, and vinegar, are among the articles produced; and there are also tanneries and dye-works. The trade is of some importance, and is facilitated by the good roads and railways. Corn, cattle, butter, cheese, wool, and timber, are among the principal exports. The educational establishments of the duchy include a gymnasium at Altenburg, with 10 teachers and 110 scholars, in 1854-5; a lyceum; normal seminary; a school of art and industry; 192 elementary schools, &c. The government is a limited monarchy; the dukedom is hereditary

Saxe-Altenburg.

Saxe-
Coburg-
Gotha.

in the male line. The legislature consists of the estates of the land (*Landstunde*), who assemble in one chamber. This chamber is composed of 21 deputies; 8 from the owners of manors, 8 from the cities, and 8 from the peasantry. A diet must be held every three years; and it is called, adjourned, and dissolved by the duke. The highest judicial tribunal for Saxe-Altenburg is the upper court of appeal, at Jena, in Saxe-Weimar; below this is the court of appeal at Altenburg; and in the third rank a court of justice in that town; and eight others in other parts of the duchy. The established church is the evangelical Protestant. Most of the inhabitants are Lutherans; and there are about 800 Roman Catholics and 1400 Jews. The military force consists of an infantry regiment, 1474 strong, which also forms the contingent to the federal army of Germany. The public revenue for 1856-8 amounted to L.107,943, and the expenditure to L.107,218. Altenburg belonged originally to the Osterland, which included all the country between the Saale and the Mulde; and it was governed by the margraves of Meissen, whose lands were purchased by the Elector of Saxony in 1428. It fell to the Albertine, or younger line of Saxony, by the compact of Leipzig in 1485, and remained in this branch of the family till 1554, when it was transferred to the descendants of John Frederick, the deposed elector of the elder or Ernestine line. But it was not till 1603 that Altenburg became a separate state, under the sons of Frederick William I., a grandson of the deposed elector; but this line becoming extinct in 1672, the most of their possessions fell to Ernest of Gotha; and from that time till 1826, formed a part of the duchy of Gotha. In the latter year, Frederick, previously Duke of Hildburghausen, obtained this duchy in exchange for his own, and founded the new Altenburg line. Some revolutionary disturbances took place here in 1830, but these were only transient; and in the following year a reform in the constitution was effected, which prepared the way for further improvements in various departments of the state. Another outbreak took place in 1848, when the revolutionary party attempted, but without success, to make Altenburg a republic.

SAXE-COBURG-GOTHA (Germ. *Sachsen-Koburg-Gotha*), a small duchy of Germany, comprising, besides several smaller portions, two separate districts, forming the duchies of Coburg and Gotha respectively, lying between N. lat. 50. 8. and 51. 20.; E. Long. 10. 15. and 11. 14. The duchy of Gotha, which forms the northern portion, is bounded by Prussia on the N.; by Saxe-Weimar on the E. and W.; by Saxe-Meiningen, Hesse-Cassel, Prussia, and Schwartzburg, on the S.; while that of Coburg is bounded on the W. and N. by Saxe-Meiningen; E. and S. by Bavaria. The area and population are as follows:—

	Sq. miles.	Pop. (1855.)
Coburg	212	44,107
Gotha	547	106,411
Total	759	150,518

The surface is in both the duchies partly occupied with mountains; that of Gotha lies on the northern slope of the Thuringian Forest, which extends along its south-western frontier; while the rest of this duchy consists of low, undulating, and very fertile land. The loftiest summits of the Thuringian chain are Schneekopf, 3119 feet high; Beerberg, 3140 feet; and Inselsberg, 2909 feet. In the duchy of Coburg there are extensive forests, and many beautiful valleys among the hills. The slope here is towards the south; and the chief river is the Itz, which flows in that direction, and falls into the Main. In Gotha, the Werra, an affluent of the Weser, takes its rise, and flows N.W.; and the Unstrut forms the eastern boundary, and flows northwards to join the Saale. The extent of arable land in the duchy is 1,139,819 acres; of wood, 600,569 acres;

VOL. XIX.

Saxe-
Coburg-
Gotha.

of meadows, 147,598 acres; of gardens, 31,766; and of waste land, 143,637 acres. Agriculture is carried on with much care, and is the chief occupation of the people. Corn and flax are the crops most generally raised; also pulse, potatoes, and other vegetables, are cultivated. The soil is very rich and fertile in the valleys and plains; and the climate is throughout the country healthy. In Coburg it is very mild; but in the mountainous parts of Gotha of a more inclement character. Pastoral employments are actively pursued by many of the inhabitants; the sheep especially are of an excellent breed, and the horses and cattle are not bad. There were, in 1852, 7063 horses; 56,207 horned cattle; 120,693 sheep; 18,266 goats; and 36,207 pigs. Fish abound in the rivers, and wild animals in the forests of the country. The German mole infests the land in vast numbers. Among the minerals, iron, coal, cobalt, and manganese, are worked; marble, alabaster, rock-salt, porcelain-clay, &c., are also found. The manufactures, especially of the duchy of Gotha, are of some importance. The weaving of linen, woollen, and cotton fabrics; paper-making; the manufacture of iron, copper, and steel; of chemical products, tobacco, beer, brandy, and vinegar, are extensively carried on; while much potash, tar, pitch, &c., are prepared in the woods. The trade of the country is considerable. Among the exports are corn, wool, salt, timber, metallic and wooden wares, porcelain, marble, lamp-black, &c. There is also a considerable transit trade, as the duchy of Gotha is traversed by a line of railway which communicates with Leipzig on the one side, and with Frankfurt on the other. The educational establishments include 3 gymnasias, a progymnasium, 2 normal seminaries, numerous industrial and other schools, and upwards of 300 elementary schools. The form of government in Saxe-Coburg-Gotha is monarchical. The highest office, which is hereditary in the male line, is occupied by the duke, who exercises the executive power; and in the legislature is limited by a diet. Each of the duchies has a separate diet, that of Coburg consisting of 11, and that of Gotha of 19 members; but, besides these, there is one general diet for the whole state, to which the Coburg diet appoints 7, and that of Gotha 14 members. The elections to the separate diets take place by means of electors equal in number to the members to be chosen, each appointed by a certain district of the country. The duration of a diet is four years, and it must meet at least in the first and last of these, while not more than six months must intervene between two diets. The duke has the power of summoning, adjourning, and dissolving the diets. Under the upper court of appeal at Jena, the judicial authority in the duchy is exercised by two colleges of justice, beneath which there are several inferior courts. There is no established form of religion; but all alike enjoy the protection of the law. The duke, and the great majority of his subjects, belong to the Lutheran Church; while there are about 2300 Roman Catholics, and 1200 Jews, in the country. The annual revenue of Coburg for the financial period 1858-61 is estimated at L.34,725, and the annual expenditure (including L.5581 interest of the debt) at L.34,342. In the administration of the public lands the annual receipts for 1855-61, were estimated at L.15,118, and the expenditure at L.10,486. As to the duchy of Gotha, the public revenue for the period 1858-61 was estimated at L.83,478 annually; and the expenditure (including L.13,303 interest on the debt) at L.83,913. The public debt amounts to L.157,346, including L.60,000 of paper money. The annual receipts of the public lands in this duchy are L.80,724, and the annual expenditure L.55,802. The military force of the country amounts to one regiment of 1860 men. Coburg, which, in the earliest times, was immediately dependent on the emperor, came, in 1348, to the house of Meissen, and through it, in 1428, to that of Saxony. By the treaty of Leipzig, in 1485, it

4 u

Saxe-
Meiningen.

fell to the Ernestine line of the latter house; and, in 1542, was made a separate duchy under John Ernest, brother of the elector, John Frederick, who regained it in 1554, after his brother's death. Meanwhile this prince had been deprived, in 1547, by the emperor of his electoral lands and dignity, but received as a compensation several lands, among which was the present duchy of Gotha. Various and continually changing divisions of the country among the descendants of John Frederick I. took place, during which Coburg and Gotha, which then formed a part of Weimar, were assigned now to one and now to another branch of the family. Gotha first became an independent state in 1640, under Duke Ernest the Pious; and was afterwards increased by the gradual addition of other lands, until it included all the territory of the Ernestine house, with the exception of Weimar. Ernest, however, died in 1675, leaving seven sons; who, after reigning jointly for five years, proceeded to a partition of the country, and founded seven new lines, viz., Gotha, Coburg, Meiningen, Ramhild, Eisenberg, Hildburghausen, and Saalfeld. Of these the second was the first to expire, in 1699, when the district of Coburg was annexed to Saalfeld. Gotha obtained, in 1707, the possessions of the extinct line of Eisenberg; and, in 1710, only the four lines of Gotha, Meiningen, Hildburghausen, and Saalfeld, remained. Frederick II., grandson of Ernest the Pious, introduced the right of primogeniture into Gotha; and the duchy has not since been divided. His family, however, became extinct in 1825. Meanwhile the house of Saalfeld, which, in 1745, assumed the title of Coburg-Saalfeld, obtained several accessions of land at the congress of Vienna; and, in 1826, a new division of the country was adopted. Gotha was then joined to Coburg, while Saalfeld and other districts were transferred to Meiningen. The ducal family of Saxe-Coburg-Gotha, formerly of Saalfeld, descending from the youngest son of Ernest the Pious, has been rendered illustrious by its connection with several of the royal families of Europe. The prince-consort of this country is the brother and heir-apparent of the reigning duke; the father of the present king of Portugal is his cousin; and another of his cousins is married to a daughter of Louis Philippe of France; while one of his uncles is king of Belgium. Important reforms in the constitution were introduced in 1846, and consequently no serious revolutionary outbreak took place in 1848.

SAXE-MEININGEN (Germ. *Sachsen-Meiningen*), a duchy of Germany, lying between N. Lat. 50. 13. and 50. 58.; E. Long. 9. 28. and 11. 25.; bounded on the N. by parts of Hesse-Cassel, Prussia, Gotha, Weimar, and Altenburg; E. by Schwartzburg and Reuss; S. by Bavaria and Coburg; and W. by Weimar. It has the form of a semi-circle or bow, curving towards the south; and its area is 981 square miles. The surface is throughout hilly, and in some parts mountainous. It is divided into the upper and the lower land; the former occupying the eastern part of the duchy, which is traversed by the range of the Thuringian Forest; the latter in the west, being occupied by the south-western slope of these mountains, and by the eastern part of the Rhön range. About the middle, between the two, lies the principality of Hildburghausen; and to the north-east of the high land that of Saalfeld; both of which are now included in the duchy of Meiningen. The principal summits are Kiefernle, in the Thuringian range, 2786 feet high; and Gebaberg, in the Rhön mountains, 2378 feet high. The principal river in the duchy is the Werra, which is formed by the union of two small streams, and flows in a north-west direction. The Saale crosses the north-east of the country; and the Milz, Steinach, and Itz, which all flow into the Main, take their rise in Saxe-Meiningen. There are several lakes in the country; and mineral springs at Salzungen and Liebenstein. With the

Saxe-
Weimar-
Eisenach.

varying altitude of the ground, the character of the climate varies; in the lowland regions it is much milder than in the highland, where frost and snow sometimes occur as early as September. In many natural productions the territory of Meiningen is very rich. The extent of arable land in the country is about 243,700 acres; of wood, 224,900 acres; of meadow land, 42,500 acres; of gardens and vineyards, 12,600 acres; and of waste land nearly 90,000 acres. Agriculture is actively carried on, though not in all parts of the country, on account of its mountainous character. Besides wheat, which is cultivated chiefly in the lowland region, potatoes and other vegetables, as well as hemp, flax, tobacco, &c., are raised. The forests furnish an important article of export; the amount of wood exported annually being more than 12,000,000 cubic feet. The live stock of the country in 1849 included 4060 horses, 63,464 horned cattle, 107,355 sheep, 19,673 goats, and 49,598 pigs. The mineral produce is also considerable. Iron, pure and argentiferous copper, cobalt, coal, porcelain earth, sulphur, marble, and salt, are obtained; and the working of the various mines employed, in 1852, 3820 hands. Manufactures are actively carried on in the country. Iron is worked; glass and porcelain are made; woolen, cotton, and linen fabrics are woven; paper is manufactured; brewing, distilling, and various other branches of industry are carried on. The trade of the duchy is considerable. The principal exports are timber, which is generally floated down the Werra; iron, hardware, glass, porcelain, paper, &c., which are conveyed to various countries, especially to America. The education of the people is well attended to in Saxe-Meiningen. There were, in 1853, 294 elementary schools, 2 gymnasias, a normal school, and various other institutions. The constitution of the state is monarchical; at the head of it stands the duke, who exercises the executive power; and is limited in his legislative functions by a diet. This assembly consists of 24 deputies; two appointed by the duke, six by the landowners, eight by the inhabitants of the towns, and eight by those of the country. The duke, and the majority of the people, belong to the Lutheran religion; and there are only about 1000 Roman Catholics, 1550 Jews, and 80 Mennonites. The judicial establishments consist of a court of appeal at Hildburghausen, subordinate to that of Jena, and several inferior tribunals. The army consists of a regiment of infantry, 1726 strong. For the period 1856-59, the annual public revenue is estimated at L.137,026, and the expenditure at L.134,993. The amount of debt on the 31st of March 1857 was L.302,607. Pop. (1857) 165,662. The present ducal family of Meiningen is descended from Bernhard, the third son of Ernest the Pious, of Gotha, who received, in the partition of 1680, the duchy of Meiningen, comprising the greater part of the county of Henneberg, which had fallen, in 1583, to the Saxon states. When the line of Coburg became extinct in 1699, Meiningen entered into a protracted contest with Gotha, Hildburghausen, and Saalfeld, for the possession of its territories; which were at last, in 1723, adjudged by the Aulic Council to Meiningen, Hildburghausen, and Saalfeld, in equal portions. Similar disputes arose on the extinction, in 1710, of the line of Romhild, part of whose possessions were adjudged, in 1714, to Meiningen. The most important changes of territory in subsequent times occurred in 1826. In the partition which then took place, Meiningen received nearly the whole duchy of Hildburghausen, whose duke obtained Altenburg in exchange; the principality of Saalfeld, and other districts, from Coburg; from Gotha, the portion of Romhild which had previously belonged to that duchy; and from Altenburg some small districts. Since that period no alterations of territory have taken place.

SAXE-WEIMAR-EISENACH (Germ. *Sachsen-Weimar-Eisenach*), a grand duchy of Germany, lying between

Saxe-
Weimar-
Eisenach.

N. Lat. 50. 25. and 51. 27.; E. Long. 9. 24. and 11. 49., consists of three principal portions, besides other smaller districts. The most westerly of the three, the principality of Eisenach, is bounded on the N. by Prussia: E. by Saxe-Coburg-Gotha and Saxe-Meiningen; S. by Bavaria; and W. by Hesse-Cassel: the central and largest portion, on the W., N., and N.E. by Prussia; S.W. and S. by Altenburg and Schwartzburg: and the third portion lies between the larger part of Reuss on the S., and Altenburg, with a smaller part of Reuss, on the N.; and between Saxony on the E., and Schwartzburg on the W. The area and population of the various parts are as follows:—

Principalities.	Circles.	Sq. miles.	Pop (1855.)
Eisenach	Eisenach.....	466	80,551
Weimar	Weimar.....	691	135,178
	Neustadt	241	48,026
Total		1398	263,755

The surface is generally undulating; and in some parts, especially in Eisenach, rises into mountains: there are also level tracts of land along the banks of the rivers. In a small separate portion of the grand duchy, the district of Ilmenau, near the S.E. extremity of the Thuringian Forest, rises Hinkelhahn, the highest summit in the country, to the height of nearly 2700 feet. Eisenach is occupied in the north by the Thuringian Mountains, more than 1300 feet high; and in the south by those of Rhon, whose highest point, that of Ellenbogenberg, has an altitude of about 2500 feet. The circle of Neustadt is traversed by several offsets of the Erz Mountains, stretching from S.E. to N.W. Among the rivers which water the grand duchy is the Saale, traversing the E. of Weimar, and receiving the Ilm, which rises in Ilmenau, and traverses the circle of Weimar. The Saale also receives the Elster and the Orla, which are the chief rivers in the circle of Neustadt. The principality of Eisenach is watered by the Weira, and by its affluents, the Fulda, Ulster, Suhl, and Orsel. In most parts of the country the climate is temperate, and the air pure and healthy. Cold and raw weather frequently occurs in the mountainous regions; while in the valley of the Saale it is extremely pleasant. In spite of many difficulties which the nature of the soil offers to the cultivator, farming is carried on with much diligence and success. The quantity of corn raised frequently exceeds the demand; potatoes, pulse, hemp, flax, hops; and on the banks of the Saale, vines are also grown. A valuable article of produce is timber. The amount of arable land in the country is about 495,300 acres; of meadow land, 81,400 acres; of gardens and vineyards, 18,750 acres; and of forests, 225,250 acres. Among the live stock of the country, the chief are sheep, of a good breed, especially in the circle of Weimar, and horned cattle, in those of Neustadt and Eisenach. In all, the grand duchy contains more than 12,000 horses, 112,000 horned cattle, 236,000 sheep, 60,000 swine, and 13,000 goats. Of the mineral produce of the land, coal, iron, copper, cobalt, and marble, are the most important articles. The chief manufactures of the country are those of woollen, linen, and cotton cloth; dyeing, and the working of metals. The greatest amount of manufacturing industry exists in the circle of Eisenach, though Neustadt is the principal seat of the wool-manufacture. Wool and grain form the staple of a trade which is actively carried on. The chief of the educational establishments in the grand duchy is the University of Jena, which belongs equally to the other Saxon duchies. (See JENA.) Besides this there are 2 gymnasia, 2 normal seminaries, and, in addition to various other establishments, 460 elementary schools. The constitution is a limited monarchy, hereditary in the male line. The executive power is in the hands of the grand duke, and the legislative is shared with a diet, consisting of

Saxo.

31 deputies; of whom 21 are elected by universal suffrage, 4 by those who possess landed property of the annual value of L.145, 5 by those who have a revenue of the same amount from other sources, and 1 by the nobility who possess estates. Justice is administered by an upper court of appeal at Jena, whose authority extends over all the Saxon duchies, the principalities of Reuss and Schwartzburg, and the duchy of Anhalt-Dessau-Cöthen. Beneath this there is an appeal court at Eisenach, and various subordinate tribunals. The grand duke, and the majority of his subjects, belong to the Evangelical Church; but there are also about 10,000 Roman Catholics, and 1430 Jews, in the country. For the financial period, 1857-59, the annual revenue of the state was estimated at L.224,757, and the expenditure at L.223,902; while the public debt, Jan. 1, 1855, amounted to L.916,259. The territories of this state, which formerly belonged to the electorate of Saxony, fell to the lot of the Ernestine line at the partition in 1485. After the deposition of John Frederick I. in 1547, numerous divisions took place among the different branches of the family; the right of primogeniture having been only introduced at a later period among these states. At the first of these divisions, in 1566, Weimar, with Gotha for its capital, was given to John Frederick II., eldest son of the deposed elector; and the rest of the country, under the name of Thuringia, to John William, his second son. The latter, however, after his brother had, by attempting to regain the dignity, incurred the fate of his father, obtained possession of Weimar, leaving Coburg and Eisenach to his two nephews, whose families became extinct in 1638. John William left two sons, the elder of whom founded the old Altenburg line; while the younger, John, had eleven sons, among whom were William, the immediate ancestor of the present family of Weimar, and Ernest, of all the other ducal houses. After this period the line of Weimar was not mixed up in the various divisions that took place among the other duchies, though it was itself once more subdivided, in 1672, into Weimar, Eisenach, and Jena. But these were reunited by the extinction of the line of Jena in 1690, and of that of Eisenach in 1741; while, in 1719, the right of primogeniture was introduced, which put an end to all further subdivisions. The most celebrated duke of Saxe-Weimar, in recent times, was Charles Augustus (1758-1828), who acted the part of a Mæcenas towards the science, art, and literature of Germany, took part in the contest against Napoleon, and received at the congress of Vienna, in 1815, along with the title of grand duke, several additions to his dominions.

SAXO, or as he is generally called, *Saxo Grammaticus*, or the *Grammatician*, was descended from an illustrious Danish family, and was born about the middle of the twelfth century. Stephens, in his edition of *Saxo Grammaticus*, printed at Sorocé, indubitably proves that he must have been alive in 1156; but he cannot ascertain the exact place and time of his birth. On account of his uncommon learning, Saxo was distinguished by the name of *Grammaticus*. He was provost of the cathedral church of Roskild, and warmly patronized by the learned and warlike Absalon, the celebrated archbishop of Lunden, at whose instigation he wrote the *History of Denmark*. His epitaph, which is a dry panegyric in bad Latin verses, gives no account of the era of his death, which happened, according to Stephens, in 1201. His history, consisting of sixteen books, begins from the earliest account of the Danish annals, and concludes with the year 1186. It bears the title, *Historia Regum Heroumque Danorum*, and first gives the history of King Hamlet. According to the opinion of an accurate writer, the first part, which relates to the origin of the Danes, and the reigns of the ancient kings, is full of fables; but the eight last books, and particularly those which regard the events of his own times, deserve the utmost credit.

Saxo-y.

He wrote in Latin; and the style, if we consider the barbarous age in which he flourished, is in general extremely elegant, but rather too poetical for history. Mallet, in his *Histoire de Dannemarc* (vol. i., p. 182), says that "Sperling, a writer of great erudition, has proved, in contradiction to the assertions of Stephens and others, that Saxo Grammaticus was secretary to Absalon, and that the Saxo, provost of Roskild, was another person, and lived earlier."

SAXONY (Germ. *Sachsen*, Fr. *Saxe*), a kingdom of Germany, lying between N. Lat. 50. 10. and 51. 23., E. Long. 11. 23. and 14. 34.; bounded on the N. and N.E. by the Prussian provinces of Saxony and Silesia, S.E. and S. by Bohemia and Bavaria, and W. by Reuss, Saxe-Weimar, Saxe-Altenburg, and Prussia. Its form is nearly triangular; its length from N.E. to S.W. about 150 miles, breadth about 75; area, 5760 square miles. The northern part of the kingdom is for the most part a level or an undulating country; but on the south it is very mountainous. The principal mountain ranges are the Erzgebirge, extending along the Bohemian frontier, and reaching their highest elevation in the Fichtelberg, 3818 feet high; the Lusatian mountains, forming a continuation of the former range on the E. of the Elbe, with Lausche, 2530 feet high; and the Elbe sandstone range, extending along both sides of the Elbe, from Dresden to Bohemia.

This last mountainous district, usually denominated Saxon Switzerland, has peculiar charms for the lovers of picturesque scenery. It is about 28 miles in length and 23 in breadth, displaying deep chasms bordered by perpendicular rocks, some naked, and others clothed with every variety of trees. Rapid streams pour from declivities, forming cascades in some parts, and in others in deep vales, meandering through verdant meadows, without their entrance or their egress being discoverable by the observer from the precipices which enclose them. Through this mass of mountains the River Elbe has worn itself a passage by a most tortuous course, and washes the bases of rocks, in some parts of nearly 1000 feet in perpendicular height. From the surface of this mountain-plain rise pinnacles of rocks, on which castles in the feudal times were erected, some of the ruins of which add to the romantic grandeur of the prospect; whilst others, such as Königstein, have had applied to them all the arts of modern fortification, and are the most impregnable fortresses in the Saxon dominions. Königstein has on its apex strong walls, surrounding buildings in which the treasures of the crown are secured in times of danger. Few spots in Europe create greater interest in the geologist, the botanist, or the lover of picturesque scenery, than this portion of the country so appropriately denominated Saxon Switzerland.

The principal river of Saxony, and that to which almost all the others contribute their streams, though not till it has left this kingdom, is the Elbe. It enters from Bohemia, and is navigable through the whole of its Saxon course. The other rivers are the Black Elster, which rises in Lusatia, and soon enters the Prussian territory; and the Spree, which comes out of Bohemia, divides itself into two branches near Bautzen, and then passes into Prussia. These rivers fall into the Elbe on its right bank. On the left bank it receives the Mulde, which is formed by the confluence of the Zwickau or western, and the Freiberg or eastern Mulde, both rising in the Erzgebirge, and flows northwards till it joins the Elbe at Dessau. The White Elster rises in the Voigtland, or south-western portion of the Erzgebirge, with many curvatures reaches the suburbs of the city of Leipzig, and, receiving there the small river Pleisse, falls into the Saale, and is ultimately lost in the Elbe above Magdeburg. The only river that does not run to the Elbe is the Neisse, which rises in the eastern corner of the kingdom, and, passing into Silesia, at length empties itself into the Oder. There are no considerable lakes in

Saxony, nor any canals, except such as are used in the mining districts for conveying the ore to the mills.

Saxony

As compared with most parts of Germany, the agriculture of Saxony is much advanced. Wherever the soil is capable of cultivation it is worked with diligence; and the more hilly and poorer soils have a good herbage, and yield pasture to numerous flocks and herds. The sides of the mountains towards the Elbe, from Pirna to Meissen, are covered with vines which yield both red and white wine, to the amount of 145,320 gallons in 1855. The extent of arable land in the kingdom is estimated at 1,839,000 acres, of meadow land at 413,000 acres, of gardens and vineyards at 45,000 acres, and of forests at 1,131,000 acres.

The arable land is chiefly cultivated on a three-course system, though in the Voigtland there are generally four courses. Rye, wheat, barley, and oats are the crops most generally raised. Notwithstanding the attention paid to farming, and the natural excellence of the soil in several parts, there is not produced more than enough of grain to supply the wants of the dense population. Peas, beans, lentils, and vetches are grown. The culture of potatoes is very extensive, and they form almost exclusively the food of the labouring classes in the mountainous districts. Tobacco, hemp, flax, wood, hops, and chicory, are grown in some parts of the kingdom, but none of them to the extent which the consumption of the country requires. The forests of Saxony form one of the chief sources of wealth to the country. Timber of excellent quality is obtained from them to the amount of more than 52,000,000 cubic feet annually. Pastoral occupations afford employment to a great number of the inhabitants. The cattle are good, especially in the Voigtland and Erzgebirge, where large quantities of butter are produced. As to the rearing of sheep, generally of a good breed, this country occupies the first rank in Germany; and poultry and pigs are also numerous. There were, in 1853, 94,925 horses, 610,836 horned cattle, 485,147 sheep, 74,726 goats, and 124,158 pigs. The wild animals of the country are at present of little importance.

Saxony abounds in minerals, and the ore is tolerably rich; which, added to superior skill and economy in working the mines and separating the metals, makes them very beneficial to the crown, to whom the greater portion of them belong. In 1854 there were in operation 362 mines in all, besides a large number of smelting-houses. The value of the silver obtained in 1850 was L.206,176; and the total value of the mineral produce about L.428,000. Besides silver, iron, lead, copper, tin, coal, sandstone, sulphur, saltpetre, and many other minerals, are found in the kingdom. Salt, however, is entirely absent, and has to be imported from Prussian Saxony.

In no part of the continent has manufacturing industry been carried to so great an extent, or occupied so large a proportion of the population, as in Saxony. It is in the mountainous regions of Lusatia and the Erzgebirge that manufactures are most extensively carried on; and in these regions there are not only many manufacturing towns, but villages, which in size, architecture, and activity of business, surpass many towns. The first manufacturing town of the country is Chemnitz. More than the half of the people are engaged in manufactures. The annual value of the whole produce of Saxon industry is estimated at thirteen millions sterling. It would include almost the whole catalogue of European manufactures to enumerate the respective kinds of goods made in Saxony. Woollens, linens, cottons, and silks for clothing; iron, brass, and copper wares; paper, leather, earthenware, hats, musical instruments, and turnery ware; various chemical and dyeing preparations; clocks, watches, swords, guns, and pistols, are all comprehended in the list of Saxon manufactures.

The commerce of a country whose inhabitants are chiefly

Saxony. occupied in manufactures, and produce an insufficiency of food for their own consumption, must necessarily be extensive. The trade of Saxony chiefly centres in the city of Leipzig, where, at the time of the three annual fairs, the greater part of the manufactures are disposed of, and contracts are made for such foreign commodities as the supply of the country demands. The roads in Saxony are generally good, and these, as well as the railways, of which there were in 1856 nearly 400 miles in operation, and the navigation of the Elbe, greatly facilitate the trade of the country. Saxony exports sheep's wool, fine woollen goods, linen and thread lace, yarn and worsted, ironmongery, cutlery, and braziers, and also books. It receives in return corn, wine, salt, colonial wares, &c. The annual excess in value of the exports over the imports of Saxony is above L.700,000; and the share of the kingdom in the net receipts of the German Zollverein amounted in 1855 to L.318,976. The quantities of the principal articles exported and imported in 1855 are exhibited in the following table:—

Principal Articles	Import	Export.	Transit
Books (cwt)	9,404	12,059	672
Cattle..... (head.)	74,608	8,044	...
Coal (cwt.)	7,734	15,621	..

The government is a monarchy hereditary in the Saxon Albertine line, and, in failure of that, in the Ernestine or Saxe-Weimar branch of the family. The king enjoys the whole executive power, confirms pardons, bestows commissions, nominates the supreme judges, and enjoys the power of making peace and war, and of concluding all treaties. In making new laws, and in imposing new taxes, the states have the right to be consulted. The legislative body is a diet composed of two chambers, which meet at the same time, and possess equal rights and privileges. The first chamber includes, besides the nobility, a deputy from the University of Leipzig, one of the Evangelical and one of the Roman Catholic clergy, the supreme magistrates of Dresden, Leipzig, and other towns, &c. In the second chamber there are twenty deputies from the possessors of manors, twenty-five from the towns, twenty-five from the country, and five representing the manufacturing and commercial interests. When the king pleases these states are convoked; but they must hold an ordinary meeting at least once every three years, and an extraordinary one on each change of ministry. The administration is conducted by a cabinet council, under which, through the privy council, orders are communicated to the departments of finance, war, domains, police, and foreign affairs. According to the budget for 1858-60, the income and expenditure each amounted to L.1,873,048; and the public debt at the end of 1857 was L.12,264,802.

The military force of Saxony is composed of the following troops:—

Infantry of the line, forming 4 brigades ..	15,748
Chasseurs 1 ..	4,005
Cavalry 2 ..	3,208
Artillery	2,430
Commanding officers.....	15

Total (exclusive of the reserve) 25,406

The whole contingent of Saxony to the German confederation is 18,000 men.

Although the royal family professes the Roman Catholic religion, the most of the people belong to the Lutheran Church. In 1855 the number of Lutherans was 1,995,891; of Roman Catholics, 36,730; of the Reformed Church, 3602; of German Catholics, 1753; and of Jews, 1200. Toleration is extended to all sects recognised by the law; and these are the Lutheran, Reformed, Roman, Greek, and German Catholic Churches; but over all alike the civil government exercises the supreme ecclesiastical power.

The educational institutions comprise the University of Leipzig, and in the endowed classical schools of Meissen and Grimma, as well as in 11 gymnasia, 9 normal seminaries, 1892 elementary schools, and various other institutions. Both the higher and lower kinds of schools are well managed, and popular education is widely spread throughout the country; so that in intellectual culture Saxony stands in the foremost rank among the nations of Europe. The fine arts have been cultivated with considerable success, and both statuary and painting receive valuable assistance from the fine productions which are contained in the collections of Dresden. The capital of Saxony is Dresden and the country is divided into four circles, as follows:—

	Sq. Miles.	Pop. (1855)
Dresden	1,669	528,714
Leipzig	1,338	454,262
Zwickau	1,785	759,328
Bautzen.....	968	296,771
Total.	5,760	2,039,075

The early history of the Saxon people is involved in considerable obscurity. According to the most ancient traditions of the people, they are represented as being the aboriginal inhabitants of the wide forests of their own country, living by agriculture and the chase. As the population gradually increased, and became too great for the country, colonies were sent out from time to time. These settled on the coasts of the Cimbrian peninsula, where they pursued a different mode of life from the inland tribes,—devoting themselves to commerce, and partly also to piracy. They rendered themselves so terrible to the Romans by their devastations that, in the reign of Theodosius, a Saxon frontier, guarded by Roman armies, was established along the shores of the German Ocean. It was from these maritime Saxons that the bands came over to colonize Great Britain.

After the ecclesiastical council at Worms in 774, Charlemagne began a long and bloody war against the Saxons. He made repeated invasions into their country, in which he was almost uniformly successful; but as soon as his back was turned the enemy was again in arms. The result of the war was that, in 804, a great part of the Saxons were compelled to adopt Christianity, and submit to the power of the Franks. They were then governed by counts, generally of Frank origin, who were afterwards raised to the rank of dukes. Of these the most celebrated is Henry the Fowler (912-936), who was elected German emperor, the first of the Saxon family who wore that crown. The duchy at that time did not correspond with the present Saxony, but with Westphalia, Hanover, and Holstein.

The nucleus of the present kingdom of Saxony was formed by the erection in 926, by Henry the Fowler, of the margraviate of Meissen, comprising the country between the Elbe, the Saale, and the Erzgebirge, as a bul-

Saxony.

wark against the Slavonian tribes beyond. In 1130 the office of margrave became hereditary in the family of Wettin, who added to the territory of Meissen their own possessions in Thuringia, Saxony, Suabia, &c.

Meanwhile the Duchy of Saxony, afterwards raised to an electorate, passed into the Ascanian family, the last elector of which, Albert III., died in 1422. As he left no issue, numerous claimants appeared for his land and dignity; but the Emperor Sigismund conferred them, in 1423, on Frederick the Quarrelsome, Margrave of Meissen, on account of the services he had rendered to the empire in the war against the Hussites.

The territory of the house of Wettin had by this time extended far beyond its original limits, and stretched from the Werra to the Oder, and from the Erzgebirge to the Harz Mountains. The accession of Frederick to Saxony gave him little additional territory, but conferred much importance, by raising him to the second place among the temporal electors. Thus the name of the purest in blood of all the German tribes, passed over to a different people; and that of Saxony came to designate what had been formerly known as the margraviate of Meissen. The country had been very much improved by the discovery of its great mineral wealth, which led to the clearing of the immense forests; but in the beginning of the fifteenth century great devastations were caused by the incursions of the Hussite troops from Bohemia. Under the wise and energetic rule of Frederick the Quarrelsome, the University of Leipzig, an offshoot from that of Prague, was founded in 1409. Frederick was succeeded in 1428 by his son of the same name, surnamed the Gentle, who died in 1464, leaving two sons, Ernest and Albert, from whom the Ernestine and Albertine families of Saxony are descended. For some time they reigned conjointly; but in 1485 proceeded to a division of the country. Ernest, the elder of the two, obtained, along with the electorate and the territory attached to that office, the greater part of Thuringia, the Voigtland, and the district of Coburg; and Albert, the ancient Meissen, and the rest of Thuringia.

The successors of Ernest in the electorate did good service to the cause of truth and freedom in supporting the rise of the Reformation. Frederick III. (1486-1525), founded the University of Wittenberg, and afforded his patronage to Luther, who was made professor there. John the Constant (1525-32) stood at the head of the protesting princes at the Diet of Spires in 1529; and John Frederick the Magnanimous (1532-47) took the lead against Charles V. in the Schmalkaldic war; and was defeated and taken prisoner in the battle of Muhlberg in 1547. For this act of rebellion he was deprived by the emperor of his electoral dignity and lands; and these were conferred on his cousin Maurice, duke of Saxony.

While the Ernestine branch of the family were thus contending in favour of liberty and protestantism, Albert and his immediate successor, who possessed the present kingdom of Saxony, were exerting their power on the opposite side. The former, in 1488, led an army to the Netherlands, and delivered from captivity Maximilian, king of the Romans, for which service he was appointed, in 1495, hereditary viceregent in Friesland, and general of the imperial army. He died, however, in 1500, in a vain attempt to subdue the Frisians; and his son George, who succeeded to the duchy, and in 1504 obtained Friesland from his brother Henry, being equally unsuccessful in his efforts, gave up this province in 1515 to the Archduke of Austria for 20,000 gulden about (L.200,000). George strongly opposed the progress of the Reformation, and attempted to exclude, by will, any Protestant prince from the succession; but dying in 1539, leaving his will unsigned, he was succeeded by his brother Henry, a Lutheran, who introduced the reformed religion into the country. His son Maurice,

Saxony.

who became duke in 1541 and elector in 1548, though he adhered to Charles V. in the Schmalkaldic war, afterwards opposed and put an end to the despotic designs of that emperor; and by the treaty of Passau in 1551, obtained for the Protestants the free exercise of their religion. Maurice's brother and successor, August (1553-86), assisted in bringing about the religious peace of Augsburg in 1555, by which the Protestants obtained equal rights with the Roman Catholics, and also did much for the improvement of the laws and constitution of Saxony. Various additional districts were added to the electorate in this reign.

The reigns of Christian I. (1586-91) and Christian II. (1591-1611) were distinguished only for religious disputes; but that of John George I., the brother and successor of the latter, includes the whole period of the Thirty Years' War, in which he played no very illustrious part. He refused the Bohemian crown, which was offered to him, and not only advised the elector of the Palatinate to do the same, but refused to afford him any assistance. He remained on the emperor's side till the arrival of Gustavus Adolphus; and after his death made terms with the emperor at Prague in 1635, by which he obtained part of the see of Magdeburg, and the two Lusatian margraviates. His eldest son, John George II., succeeded in 1656; while the younger sons, August, Christian, and Maurice founded the lines of Wossenfels, Merseburg, and Zeitz, which became extinct in 1746, 1738, and 1718, respectively. John George III. (1680-91), the son and successor of the last elector, distinguished himself by the assistance he gave to the emperor against the Turks in Hungary, and against France on the Rhine.

After the short reign of John George IV., Frederick August I., surnamed the Strong, succeeded in 1694; and, in order to obtain the elective crown of Poland, went over, in 1697, to the Roman Catholic Church. By this increase of power and territory, however, he involved himself in a war with the greatest soldier of the age, Charles XII. of Sweden, in which Saxony was invaded by the Swede, and suffered the loss of an immense amount of money and blood. Frederick August II., who succeeded his father in 1733, was also elected King of Poland. During this reign, as in the preceding, the wars and extravagance of the court reduced Saxony to the lowest pitch of misery. In the war of the Austrian succession, Frederick August took part with France and Prussia against Austria; but in the Seven Years' War he placed himself on the imperial side. In the latter contest Saxony was devastated alike by friend and foe, and was the scene of many of the victories of Frederick the Great.

The wretched state of the country began to be ameliorated in the long reign of Frederick August III., who obtained the electorate in 1763 at the age of thirteen, and ruled at first under the guardianship of his uncle Xaver. A system of strict economy, justice, and mildness was introduced; the people were relieved from many burdensome imposts; the use of torture was abolished; and much was done for the material improvement of the country. A rising of the peasantry, which took place in 1790, was put down without loss of blood, and the grievances complained of were removed. In the wars which followed the French Revolution, Saxony took part with Prussia at first; but after the power of that kingdom was overthrown by the decisive battle of Jena in 1806, Frederick August made peace with Napoleon, and was made, with the title of king, a member of the Rhenish confederacy. By the peace of Tilsit in the following year he obtained several accessions of territory, and the sovereignty over the newly erected grand-duchy of Warsaw. During this time of his prosperity the monarch acted a very upright and honourable part, in not taking advantage of his power to enrich himself at the expense of the surrounding small states, as he might easily have done. But a great reverse of fortune befell him after

Saxony. the fall of Napoleon. Saxony was treated as a conquered country; the king was kept in confinement for some time; and a partition of the kingdom was effected by the Congress of Vienna, whereby, besides the loss of the duchy of Warsaw, an area of 7911 square miles, with a population of 845,218, was ceded to Prussia, to make up to that kingdom for its part of Poland, which Russia obtained.

Notwithstanding this spoliation of more than half its territory, Saxony has since risen to a more flourishing and prosperous condition than ever. Frederick August I. (as king) died in 1827, having deservedly obtained the surname of the Just; and was succeeded by his brother Anthony, who carried on the various measures of reform which his predecessor had begun in the later years of his reign. Still the people suffered under many grievances, and had as yet very little share in the legislative power. The outbreaks which took place in 1830 in Dresden and Leipzig did not indeed cause any serious disturbance; but they led to the introduction of a new constitution in the following year. On the death of the king in 1836, his nephew, Frederick August II., who had been regent since 1830, ascended the throne.

The constitutional system now established did not succeed altogether in the best possible way. A powerful party was formed in opposition to the government; and in the year 1843 violent contests began, in which the opposition gradually gained the upper hand. The chief points in dispute were the freedom of the press and the publicity of judicial proceedings. The government followed the fatal policy of delaying to yield as long as possible, so that the concessions which would in 1843 have been received with universal joy, were granted in 1846 without any effect. An attack was made in Leipzig in 1845 upon Prince John, the heir-apparent; and having been put down by the military, led to a still more violent opposition on the part of the popular party. The ministry, however, still held their ground during the stormy session of 1845-6; but were at last compelled to resign in March 1848, when a liberal cabinet was formed. Various changes were introduced in the following year, especially with regard to the mode of electing the legislature, but these were not of long continuance; and the diet of 1852, elected after the old manner, restored the constitution almost entirely as it was before 1843. Falkenstein, who was one of the ministry previous to 1848, and resigned in that year, is now again in the cabinet, and has been since 1853. In 1854, the king was killed by an accident while travelling in the Tyrol, and was succeeded by his brother John, the present king.

SAXONY (Germ. *Sachsen*), a province of the Prussian monarchy, lying between 50. 55. and 53. 5. N. Lat., 9. 22. and 13. 21. E. Long.; bounded on the N.E. by the province of Brandenburg, S. by the kingdom of Saxony and the Saxon duchies, W. and N.W. by Electoral Hesse, Brunswick, and Hanover. Area, 9760 square miles. It has several detached portions lying among the Saxon duchies, and encloses portions of these as well as the duchies of Anhalt and the principalities of Schwartzburg. It is for the most part a flat country, consisting of the land lying between the Thuringian Mountains in the S., the Harz Mountains in the W., and the Elbe in the E. and N. The Harz Mountains belong partly to this province, and within its limits is their highest summit, the Brocken, a granite peak 3508 feet high; and another called Konigsberg, which attains the height of 3100 feet, besides others of less elevation. To that part of the Thuringian mountain which is included in the province belongs the summit of Dolmar, 2100 feet high. The lower portions of the country are watered by the Elbe, which enters the province at its south-eastern extremity, and flows in an irregular course to the north-west, never very far from the borders of Brandenburg, which it touches in the lower part of its

course. This river receives, either directly or indirectly, all the other streams of Saxony. The Saale flows northwards from the Thuringian Mountains into the Elbe; the Mulde, also an affluent of the Elbe, flows in the same direction further east, and nearly parallel to the Saale; and the Unstrut flows from the west and joins the Saale. The whole of the soil of Saxony is not only very fertile, but exceedingly well cultivated, and it enjoys a mild and salubrious climate. The extent of arable land in the province was, in 1852, 3,377,069 acres; of gardens, vineyards, &c., 70,487 acres; of meadows, 424,701 acres; of pasture land, 394,597 acres; of forests, 955,511 acres; and of waste land, 1,403,689 acres. Cattle, sheep, and horses are raised in great numbers in Saxony. There were in 1855, 152,485 horses; 502 mules and asses; 522,380 horned cattle; 1,838,946 sheep; 144,255 goats; and 332,490 pigs in the province. The mineral productions comprise silver, iron, lead, copper, coal, and salt. Marble, alabaster, granite, sandstone, and porcelain clay are also found. Manufactures are actively carried on here, especially those of woollen and cotton cloth. Education is well provided for, and the proportion of the population who have enjoyed its advantages is higher here than in any other province of Prussia. There are in all 2872 public elementary schools, with 3794 teachers and 304,318 scholars; 66 intermediate schools for boys, with 11,480 scholars; 49 girls' schools, with 11,036 scholars; 11 normal seminaries; 4 progymnasias; and 21 gymnasias. Saxony contains also one university, that of Halle, with which the former one at Wittenberg has been united. The great majority of the inhabitants are of German extraction; 1,738,130 belong to the Evangelical Church, 118,064 to the Roman Catholic; 5 to the Greek Church, 16 are Mennonites, and 5320 Jews. Saxony is divided into three circles, as follows:—

	Square Miles.	Pop. (1855).
Magdeburg	4453	727,052
Merseburg	3999	781,947
Erfurt	1308	352,536
Total.....	9760	1,861,535

The greater part of this province till 1815, formed part of the kingdom of Saxony; but by the congress of Vienna it was annexed to Prussia.

SAY, JEAN BAPTISTE, a French political economist, was born at Lyons on the 5th of January 1767, of an honourable commercial family of Protestant refugees. Say was originally designed for the family trade, but having always been of a meditative turn, he showed early a decided fondness for letters. In his youth he assisted Mirabeau and Clavieres, and during the Reign of Terror he was one of the conductors of the *Decade Philosophique*, the sole scientific and literary monument of that bloody time. Being requested to take part in the affairs of the tribunate by Bonaparte, then first consul, he remained faithful to his political convictions; and when Napoleon was subsequently raised to the empire, Say voted against it, and withdrew in 1804. He was for a time director of taxes for the department of Allier, but afterwards resigned this post to popularize the science of Adam Smith and Quesnay. Say was not a discoverer in political economy, but was a very intelligent expounder of the principles of that science as originated by others. His distinguishing merit is that of a skilful exponent of truths and principles already known and fully established; and except in his inquiry relating to gluts, he left the science of political economy exactly in the same state as he found it. He died at Paris on the 16th of November 1832. Say's principal works are—*Traité d'Economie Politique*, 2 vols., 1802; and 5 vols. in 1826, afterwards expanded into the *Cours Complet d'Economie Politique Pratique*, 6 vols., 1829; *Catechisme d'Economie Politique*, 1815, fifth edition, 1826. Another

Say.

Scala Nova work, entitled *De l'Angleterre et des Anglais*, was written after a tour in that country.

Scaliger.

SCALA NOVA, a seaport town of Asiatic Turkey, at the head of a gulf of the same name, 40 miles S. of Smyrna. It is a wretched, meanly-built place, on the side of a hill rising from the sea. Some wine is made here; and an active trade was formerly carried on with Egypt and Salonica. Pop. 20,000.

SCALE, a mathematical instrument, consisting of several lines drawn on wood, brass, or silver, and variously divided, according to the purposes it is intended to serve; whence it acquires various denominations, as the *plain scale*, *diagonal scale*, *plotting scale*, and the like. (See GUNTER.)

SCALE, in *Music*. See MUSIC. The name is derived from *scala*, a ladder, or flight of stairs, and has reference to the disposition of the notes that ascend or descend upon the written or printed musical stave.

SCALIGER, JULIUS CÆSAR, a learned critic, poet, physician, and philosopher, was born at the castle of Riva, in the territories of Verona, in 1484, and is said to have been descended from the ancient princes of Verona, though this is not mentioned in the letters of naturalization which he obtained in France in 1528. He learned the first rudiments of the Latin tongue in his own country; and in his twelfth year was presented to the Emperor Maximilian, who made him one of his pages. He served that emperor seventeen years, and gave signal proofs of his valour and conduct in several expeditions. He was present at the battle of Ravenna in April 1512, in which he had the misfortune to lose his father, Benedict Scaliger, and his brother Titus, on which his mother died with grief; when, being reduced to necessitous circumstances, he entered into the order of the Franciscans, and applied himself to study at Bologna. But soon afterwards, changing his mind with respect to his becoming a monk, he took arms again, and served in Piedmont, at which time a physician persuaded him to study physic, which he did at his leisure hours, and also learned Greek; and at last the gout determined him, at forty years of age, to abandon a military life. He soon afterwards settled at Agen, where he married, and began to apply himself seriously to his studies. He learned first the French language, which he spoke perfectly in three months; and then made himself master of the Gascon, Italian, Spanish, German, Hungarian, and Slavonian; but the chief object of his studies was polite literature. Meanwhile, he supported his family by the practice of physic. He did not publish any of his works till he was forty-seven years of age, when he soon gained a great name in the republic of letters. He had a graceful person, and so strong a memory, even in his old age, that he dictated to his son two hundred verses which he had composed the day before, and retained without writing them down. He was so charitable, that his house was as it were an hospital for the poor and sick; and he had such an aversion to lying, that he would have no correspondence with those who were given to that vice; but, on the other hand, he had much vanity, and possessed a satirical spirit, which created him many enemies. He died of a retention of urine in 1558. The following is a list of his principal works:—*Commentarii Hippocratis librum De Insomniis*, Græc. et Lat., 8vo, Lyon, 1538; *De Causis Linguae Latine*, Libri xviii., 4to, Lyon, 1540—unquestionably a great work; *Poetices Libri Septem*, folio, Lyon, 1561—a monument of grammatical knowledge; *In Theophrasti Libros sex de Causis Plantarum Commentarii*, folio, Geneva, 1566; *Commentarii in Aristoteli adscriptos Libros Duos de Plantis*, Geneva, 1566; *Aristotelis Historiæ Animalium Liber Decimus*, Lyon, 1584; *Animadversiones in Theophrasti historias Plantarum*, Lyon, 1584; *J. C. Scaligeri adv. Desid. Erasmus Orationes Duæ, Eloquentiæ Romanæ Vindices*, Toulouse,

1621—an exceedingly virulent attack upon Erasmus. The Latin poems published by J. C. Scaliger did not tend greatly to increase his fame.

SCALIGER, *Joseph Justus*, one of the most learned critics and writers of his time. He was the son of Julius Cæsar Scaliger, and was born at Agen, in France, in 1540. He studied in the college of Bordeaux, after which his father took him under his own care, and employed him in transcribing his poems. By this means he obtained such a taste for poetry, that before he was seventeen years old he wrote a tragedy upon the subject of *Œdipus*, in which he introduced all the poetical ornaments of style and sentiment. His father having died in 1558, he went to Paris the year following, with a desire to apply himself to the Greek tongue. For this purpose he for two months attended the lectures of Turnebus; but finding that in the usual course he should be a long time in gaining his point, he shut himself up in his closet, and by constant application for two years gained a perfect knowledge of that language. After this he applied to the Hebrew, which he learned by himself with great facility. He made no less progress in the sciences; and his writings procured him the reputation of one of the greatest men of that or of any other age. He embraced the reformed religion at twenty-two years of age. In 1563 he attached himself to Louis Casteignier de la Roche Pozay, whom he attended in several journeys; and in 1593 he was invited to accept of the place of honorary professor of the University of Leyden, which he complied with. He died of a dropsy in that city in 1609. He was a man of great temperance, was never married, and was so close a student, that he often spent whole days in his study without eating; and though his circumstances were always very narrow, he constantly refused the presents that were offered him. The following are the principal works of this great critic, whose fame has well-nigh eclipsed that of his proud and subtle father:—*De Emendatione Temporum*, folio, Paris, 1583—his greatest work, connected with which was afterwards published his *Thesaurus Temporum, complectens Eusebii Pamphili Chronicon cum Isagogicis Chronologiæ Canonibus*, 2 vols., Amst. 1658. Among his minor works are his edition of Arabian proverbs, his *Poemata* and *Epistolæ*, besides numerous commentaries, annotations, and editions of Varro, Theocritus, Manilius, Catullus, Tibullus, Propertius, Seneca the dramatist, Ausonius, Nonnus, Festus, and many other ancient authors. In all of those works we can trace the hand of the profound scholar and the sagacious critic; but his works are too frequently disfigured by great bitterness of spirit, and by the disgusting invectives which he showers on his opponents. The collections entitled Scaligerana were the idle pretensions of his father to an illustrious origin, and were collected from his conversations by one of his friends, and being ranged into alphabetical order, were published by Isaac Vossius.

SCAMANDER, or XANTHUS, a river of the Troad, which has attained a world-wide fame by means of the poems of Homer, and now bears the name of *Bunarbashisu*. According to the poet, it was called Xanthus by gods, and Scamander by men.

SCANDERBEG. See TURKEY.

SCANDEROON, ISKENDEROON, or ALEXANDRETTA, a town of Asiatic Turkey, the seaport of Aleppo, from which it is distant 65 miles W.N.W., on the S.E. shore of the bay of Scanderoon. It is a meanly-built place, and very unhealthy on account of the marshes that surround it; but some improvement has recently been effected by the draining of one of the largest of these, and the harbour is the best on the Syrian coast. It is one of the principal seats of the maritime trade of Syria. Pop. 800.

SCANDINAVIA, the ancient name of Norway, Sweden, and Denmark.

Scaliger

Scandi-
navia.

SCANDINAVIAN LITERATURE.

Scandinavian literature.

THE literature of Scandinavia is the literature of our ancestors. There has been of late years a determined bias to show our ancestry from the Germans; but with the Germans proper we have little or nothing to do. It is with that branch of the great Gothic race, stretching from Norway to the frontiers of France, including the Scandinavians, the Holsteiners, the Dutch and Flemish, that we claim kindred, and from whom we derive a portion of our blood and the freedom of our institutions. It has been well said, that we are not even Anglo-Saxons, but English, being amalgamated of the ancient Britain, the Roman, the Anglo-Saxon, and Scandinavian. They who endeavour to trace our paternity to the Germans proper, will find that we have few traces in our language, our political constitution, or our national character of such paternity. The Germans are, and always have been, an inland, sedentary, industrious, but unenterprising people, having no fleets, no colonies, no free institutions, except such as they have of late years copied from us. But when we turn to the natives whose maritime habits led them to locate themselves on the sea-board of the greater part of Western Europe, we discover our true progenitors. They, and especially the Scandinavians, have always had a determined tendency to political liberty, to ships, maritime adventures, colonization, and foreign conquest. The language of the Anglo-Saxons—a Scandinavian, and not a pure German race, Anglen, whence they came, being still a portion of Holstein, a Danish province—Dean Trench, a great authority, tells us, constitutes sixty parts of our present English out of every hundred, thirty only being from the Latin, five from Greek, and five from other sources. It is extraordinary, therefore, that we have not made a more intimate and educational acquaintance with a language which is the great foundation of our own, and a literature so illustrative of the great sources of our descent, and our present stamp of character.

The earliest literature of Scandinavia is of an antiquity the date of which is vastly remote, and its limits untraceable. It consists of those accounts of its gods and heroes which had been handed down from age to age by a class of poets and oral historians educated for the purpose, and styled Scalds and Sagamen. The Scalds, or poets, attended the kings and princes both in their palaces at home and on their martial expeditions, and sung the history of the gods and the exploits of the sovereigns and distinguished heroes. The Sagamen appear to have not only related their histories and legends in palaces, but far and wide amongst the people. This system of oral literature continued till Christianity introduced letters, in or about the year 1000. It is true, that the Scandinavians possessed long before that a rude species of letters called Runes, which were cut on staves of wood, called Runstafvar, or Rimstafvar, or on rocks and stones, as memorials of some great event. Their Bauta-stenar, or stones of memorial, had Runic inscriptions upon them, and they had staves of a calendar-like character cut with them, called Kaffar; they had also arrived so far as to write letters on great occasions in them, as the letter which Anschar the Christian missionary, the apostle of the North, received from King Björn. But however extraordinary, they never appear to have conceived the idea of preserving their knowledge in them, but continued to commit their histories, their poems, and their tales, to the memories of their Scalds and Sagamen.

Wherever Christianity came in the shape of Romanism, which was the case sooner or later all over Europe, it put down the original literature or traditionary lore of the country, because it was inseparably mixed with the pa-

Scandinavian literature.

ganism of the people. This was the case in Scandinavia, and so completely did it root out the ancient knowledge, that neither in Scandinavia itself, in England, nor in Normandy, were there left any traces of the grand mythologic and heroic compositions which had filled the Scandinavian mind for countless ages up to that period. All this ceased to exist, except in a much metamorphosed form in the minds of the common people, in what are called Folks-Sagor, to which we shall, ere long, allude. Odin, Thor, Frigga, and Iduna, became mere names, and their deeds are no longer remembered as theirs. Fortunately for some very noble and curious compositions, these were preserved by such of the Scandinavians who had fled to Iceland from the oppression of some of their conquering monarchs, and who there retained a greater independence of the Romish Church. In that wild volcanic island, amidst its stormy northern seas, the ancient order and arts of the Scalds were preserved. The Scalds went thence to attend the courts and campaigns of the Scandinavian kings, and learned men, by their lamps during the six months' perpetual darkness of their winters, penned down what yet remained of the pagan orature of their ancestors. The first of these was Samund Sigfusson, surnamed Froðé, or the Learned. He was born in 1056, only about a year before Christianity was introduced into the island by Isleif, the first bishop. He was, therefore, though educated a Christian, also a Scald; and thus sympathizing with the Scalds gone before him, he wrote down all that remained of their great mythologic and heroic poems, now remaining under the name of the Elder, or Rhythmical Edda. After him followed Ari Hinn Froðé, who began the chronicles of Iceland in the *Landnama Bok*; and Snorre Sturleson, the author of the Second or Prose Edda, and the *Heimskringla*, or *Chronicle of the Kings of Norway*. These, with a great number of romantic and popular sagas, constitute the mass of the ancient Norse literature, which, escaping the annihilating hands of the Romish priests in that remote island, which remained an independent republic till 1261, astonished the learned world of Denmark and Sweden, by their discovery in the middle of the seventeenth century. For a full account of these extraordinary productions, we must refer to Howitt's *History of Northern Literature*, where a complete analysis and copious translated specimens of the Eddas are given, and to Mr Laing's translation of Snorre Sturleson's *Heimskringla*. Our space will admit of only the most cursory notice of them.

THE ELDER, OR SAMUND'S EDDA.

On entering on these ancient books, we are immediately struck with the corroborative evidence which they furnish of the eastern origin of the Goths, the fathers of the Scandinavians. As all languages, so all mythologies run in lines, which converge to one common centre, the original source of the human race, and consequently of all tongues and primeval faiths—Central Asia. And little as we might expect it, no sooner do we open the ancient religious books of Scandinavia, than we are carried back thither. Our northern people are a people of eastern origin. Odin and his Asar, as Asiatics, declared themselves to be from the great Svithiod, a country which appears to have been the present Circassia, lying between the Black and Caspian Seas. The whole of their memories abounded with the proofs of it. They brought with them abundant eastern customs, those of burning the dead, and burying under mounds, like the tombs of Ajax and Achilles on the Phrygian plain, or which are still seen on the plains of Persia and Tartary. They

Scandinavian literature.

practised polygamy, looked back with imperishable affection to the great Svithiod, to the primitive district of Asgard, and the city of Gudahem, or home of the gods. They transferred a religion bearing the primal features of those of Persia, India and Greece, to the snowy mountains of Scandinavia. The Asar and the giants were in constant hostilities, like the gods of Greece and the Titans. They had their three principal deities,—Odin, Thor, and Loke, the latter the evil principle, the Pluto of the Greeks, the Ahriman of the Persians, the Siva of the Hindoos. They had their gods of thunder, of war, of eloquence, and of the sea. They had the actual Venus of the Tanais, the great deity of the Persians, the very name Vanadis suggesting that of the Hellenic Venus. They had in Balder the Vishnu of India, and a more beautiful Pan. The gods of Scandinavia are actually described as sitting on Idavalla, or Mount Ida; and Odin, Thor, and Loke, like the Jupiter, Mercury, and Mars of Greece, make excursions amongst mankind, and indulge in singular love adventures. You have the strife of Light and Darkness in Balder and Höder, as in Ormuzd and Ahiman; you have a tripart divinity,—the Jove, Neptune and Pluto of Greece, the Brahma, Vishnu, and Siva, find their counterparts in Odin, Thor, and Balder. Instead of the ox Abudad, we have the cow Audumbla; instead of genii, nymphs, dryads and nereids, we have elves, dwarfs, and trollquiuna. All the powers of nature are shadowed forth in this great pantheistic system, in the various deities of the various eastern mythologies; there is a great and sublime deity, far above all semi-human deities, that stand in greater proximity to men, and then comes a final fire, Regnarok, like that of the Persians, and the grand mundane catastrophe of the Christian creed. Through the whole, indeed, we trace the earliest traditions of the primitive world, the Adam and Eve in Ask and Embla, the Meschia and Meschane of Persia; the very Fates are there, the Nornor, the Dog of Hell, and the Tree of Life. That tree so conspicuous in the Hebrew system, in the remains of Nineveh, and in the Christmas customs of Germany, has assumed in the Scandinavian mythology, through the grand imagination of poet-priests of unknown ages, a magnificence which is without a parallel.

The *Rhythmical Edda* consists of eight-and-twenty poems; these are divided into two parts. The first part contains everything relating to the mythology and morals, to the histories of the gods and heroes of the Scandinavian world. From the three first, the *Völuspá*, or song of the Vala or prophetess; *Vafthrudner's* song and *Grimner's* song, we obtain a complete view of the uranic, cosmogonic, and mythic system of the ancient Scandinavians. In the *Hávamál*, or Odin's high song, we have a system of ethics which astonish us by their profundity and knowledge of human life and motives. The maxims contained in it more resemble the Proverbs of Solomon than anything else in human literature. One is surprised to find, too, the whole *philosophy of clothes* contained in a single strophe a thousand years before either Montaigne or Carlyle enunciated it:—"I hung my garments on the two wooden men who stand on the wall. Heroes they seemed to be when they were clothed! The unclothed are despised!"

In the second part of the *Edda*, we come upon a still more interesting discovery, the original of the great German poem, *The Nibelungen Lied*. The Germans, with a natural egotism, claim this great story as their own. They call the *Nibelungen Lied* the *Iliad* of Germany, and place it above all ancient poems, except that of Homer. But here we have not a *Nibelungen Lied*, but the original materials of it,—a cycle of ancient Icelandic heroic poems that have no parallel in all the treasures of ancient literature. They are to the *Nibelungen Lied* as the songs of the Rhapsodists, which Homer elaborated into his immortal epic. The *Nibelungen Lied* has been elaborated from

Scandinavian materials, and these materials exist in the *Edda* in a form than which Greece itself has nothing prouder to show. The stories and characters of these poems differ in many particulars from the German version. Siegfried here is named Sigurd, Chrimhilde, Gudrun; Brunhilde is a far finer character, and the final tragedy proceeds, not from Chrimhilde, but from Atle, the Etzel of the German story. These tragic events and heroic personages, which for ages filled all the North with love and admiration, and which the poems themselves declare "shall live for ever in all lands," possess a colossal and powerful nature. They are the expressions of the souls of poets existing in the primæval and uneffeminated earth. They are limnings of men and women of godlike beauty and endowments, full of the vigour of simple but impetuous nature. They have gigantic proportions; a thrilling revelation of beauty; a terrible force of passion, which lead to crimes and desolation of life, which are unsurpassed by the awful fatalities of the Atride family, the madness of Orestes, the terrible story of Medea, or the sorrows of Iphigenia or Antigone.

The *Prose Edda* was compiled by Snorre Sturleson, and deals with the same topics in prose as the *Elder Edda* has presented in poetry, mixed up with many other matters of an inferior or extravagant character. It betrays the lower taste of the age, though including some striking sagas.

The *sagas* are the prose recitals of Sagamen, as the *Eddaic* poems and the heroic lyrics, as the well-known death-song of Ragnar Lodbrog were of the Scalds. The sagas comprehended, indeed, almost every species of narrative in prose. There were great historic sagas; sagas relating to local and familiar matters, romantic sagas and heroic sagas. In the sagas it is difficult to say where fable ends, where fact commences, or how much of one is amalgamated with the other. Saga literature is a world of itself. It consists of above 200 volumes, lists of which may be seen in the *Series Dynastarum et Regum Danie*, of Torfæus, in Muller's *Saga Bibliothek*, and in Biorn Halderson.

Of all the sagas, however, the great historical one of the *Heimskringla* is the most important. This is so called from the leading word of the manuscript, "*Heimskringla*," the home-circle, meaning the circle of the earth, the home of man. It is a most admirable history of a great portion of northern Europe, from about the time of the Christian era to 1177 A.D., or the twenty-third year of our own Henry II., a hundred and eleven years after the Norman Conquest. It traces Odin and his Asar from the East; gives the settlement of Scandinavia, the contests of the petty kings of Norway, Denmark, and Sweden, till they became three compact kingdoms, each under its own sovereign; the Vikings expeditions to all parts of the world; the discovery and settlement of Iceland and Greenland; the discovery of the coast of America; the conquest of Normandy and England; and this is done, not in the dry manner too common to chroniclers, but with a life and freshness belonging only to a great and dramatic genius. The actors are alive; the details have all the simple grandeur and vivid colouring of the narratives of the Bible. Mr Laing's translation has made this accessible to the English reader.

The *Romantic Sagas* of Iceland resemble the great romances of the middle ages, in which, without much regard to times or geography, the most wonderful stories of kings, heroes, giants, ferocious and terrible beasts, as well as beautiful countries and beautiful maidens, figured, such as now constitute the *Volks-Bücher* of the German peasantry.

The *Remaining Literature of Iceland* consisted of the *Grágás* or Laws; and at a later period, supposed to be of the twelfth or thirteenth century, the *Konungs Skygsja*, or *Mirror of Kings*, supposed to be addressed by King Sverrer to his son, a work curious for its moral inculcations and its melancholy description of the island. We may add that

Scandinavian literature.

Scandinavian literature.

Iceland has continued to the present time to have its literature, chiefly of an economical and practical kind, many of which productions have been printed in Denmark by societies formed for that purpose. Iceland, too, has also had its poets, the chief of whom, Jon Thorlakson, is known to our countrymen by his translation of Milton's *Paradise Lost* and Pope's *Essay on Man* into Icelandic, as well as by a fine poem on the "English and Foreign Bible Society." He also translated Klopstock's *Messiah*. Dr Henderson found this venerable poet in 1814 living on an income of L.6, 5s. sterling. Other of the Icelandic poets of great popularity were Jon Jonsonius, Stephen Olafson, Benedict Jonson Groendal; Thorvald Bodvason, the translator of Gellert's "Christian" and Pope's "Messiah;" Professor Finn Magnussen, and Sigurd Peterson. Iceland had also its historians and eminent antiquarians and naturalists. Amongst these are Jon Olafson, a learned orientalist, Olaf Olavius, a naturalist; Halder Jacobson, the historian of Rolf of Normandy and of Iceland in the eighteenth century; Arne Magnussen, a great antiquary; and Finn Magnussen, the learned editor of the *Elder Edda* and of the great *Lexicon Mythologicum*; Jon Eyricksson, president of the Icelandic Society in Copenhagen, and a learned writer on Icelandic mythology and history, &c. &c.

THE FOLK'S SAGA OF SCANDINAVIA.

But perhaps no form of Scandinavian literature furnishes such striking evidence of our descent from the Scandinavian root as the *Folks-Sagas*. These have been collected only in modern times; but they are the true productions of ancient, not of modern Scandinavians. When the Papal religion had put down the scalds and sagamen, and so completely extinguished the eddas and the mythic stories of the Odin period, that, except in the secret archives of Iceland and the hidden wastes of an old German library, they were no longer to be found; when the Latin had superseded the vernacular tongue amongst the learned all over Europe, and monkish legends and dry chronicles had displaced the imaginative compositions of Scandinavia, the spirit and traditions of these old mythologies and wonder-worlds still remained fast rooted in the minds of the people. Though Catholicism became the people's religion, and the miracles and *diablerie* romances of the convent were engrafted on their prior credence, their forefathers' faith became their fireside literature. The marvels of the Pagan faith survived the faith itself; and now, when the monkish twaddle with which the Roman priests abused the imagination of the population wherever they prevailed, has again sunk into matter of laughter, the legends of the old creed of the North show themselves everywhere in a revived and immortal bloom. True, they are greatly metamorphosed, but they are there. The names of Odin and Thor, Frigga and Iduna, are forgotten; but their deeds and potency remain, and cast a spell on all the nurseries of England, Normandy, and Germany, as well as over those of all the north of Europe. All the witch, fairy, and dragon lore which Odin and the Asar brought out of the East exist under new names in the saga lore of our infancy; in *Jack the Giant-Killer*, *Cinderella*, *Bluebeard*, *The Little Old Woman Cut Shorter*, *The Pig that would not go over the Brig*, *The Giant who smelt the Blood of an Englishman*, *Puss in Boots*; nay, even traces of *Dick Whittington and his Cat* and *Baron Munchausen*.

These Folk-Sagas have of course much in common with the German *Kinder und Haus-Märchen*, as collected by the brothers Grimm; but they have many features not to be found in those of Germany. Of these the collection of Folk-Sagas by Olaf Hylten Cavallius and George Stephen is a good specimen of the Swedish ones. The Danish are equally abundant. The English reader will find a good assortment of them in Dasent's *Tales from the Norse*, lately published.

THE VISOR, OR OLD BALLAD POETRY OF SCANDINAVIA.

Scandinavian literature.

The extinction of Odinism, with its scaldic and saga system, by Christianity, or rather by Romanism, was insufficient to extinguish that poetic and imaginative spirit which had lent its life to them. This spirit ere long manifested its indestructible presence in new forms. As the saga revived in the form of the Ridder-Romanen, such as that of *Diedrich of Bern*, and the Folk-Sagor, so the scaldic fire reappeared in one of the most brilliant forms of this old literature,—that of the Kampe-Visor, or heroic ballads, followed by the Folk-Visor, or popular ballads. The Kampe-Visor, though the ancient religion had fallen, and the model of the Eddaic hymns was abandoned, still celebrated the very heroes of the mytho-heroic period. These heroes and heroines lived again, as it were, in new bodies. Though the Visor are supposed, at least the most ancient of them, to have been composed in the thirteenth, fourteenth, and fifteenth centuries, "Chrimhilde's Revenge," "Brynhilde's Song," Sigurd, under the name of "Sivard Snarensvend," reappeared in them. Diedrich of Bern and Vidric Verlandson, or son of Wayland the smith, once more performed their prodigies of valour. Giants, trolls, and dwarfs still lived amid saints, angels, and abbesses. But the Kampe-Visor present only the first phases of this class of national ballads. They continued to appear down to very modern times, and embodied the varying characteristics of the successive ages. The Scandinavian collectors very properly divided them into heroic ballads, ballads of the necromantic and supernatural, historic ballads, and ballads of love and romance.

These ballads of Scandinavia, the early volumes of which were collected and published 174 years before Bishop Percy published his *Reliques*, nevertheless resemble in fact, in spirit, manner, and topic, those of England and Scotland. They are the common expression of the life and feelings of a common race under the prevailing influences of the same period; and what is more, in many of them the subject is identical, showing that they were, as far as England, Scotland, and Scandinavia were concerned, drawn from one common source, where the people and the language were one.

Our space forbids us to note these exact identities; they can be seen in the authorities referred to, as well as the artistic peculiarities of these splendid ballads. We may, however, notice one of the most remarkable, the "Omquidé," or refrain, which reminds one greatly of those in the English and Scottish ballads, "Binnorie, O Binnorie," "The sun shines fair on Carlisle wall," &c. These refrains display, in the nameless poets, the same intense love of nature as those of the Robin Hood ballads. In such refrains as—"The Linden Tree which quivers in the Grove," "The Fragrant Rose Wood," "The Lily and the Lily Tree," a poetic imagination abounds. See Howitt's *Northern Literature*, where many translations of such ballads are given.

The first collection of Danish ballads was published through Tycho Brahé inducing Vedel, the collector, to recite some of them to the queen of Sweden when on a visit to his observatory, Uraniburg. They appeared in 1591. Other volumes from time to time have been added by Syv, Abrahamson, Nyerup, and Rahbek, &c.; and they have successfully inspired many of the modern Danish poets and romancers, Evald, Oelenschläger, Ingeman, &c. The same may be said of the Swedish ballads, which are equally splendid.

THE MODERN LITERATURE OF DENMARK.

With the Visor which we have been noticing, the literature of Scandinavia in reality divides itself into two nationalities, the Danish, including the Norwegian, and the Swedish. We now come upon a wide intellectual desert,

Scandinavian literature.

stretching itself betwixt the ancient and modern literatures of these countries. The modern literature of Scandinavia is very modern indeed. The ancient literature may be said to terminate with the Visor and Folk's-Sagor in the thirteenth century. These survived amongst the people, but these only; and it was not till the sixteenth century that a fresh Scandinavian literature in the mother tongue began to show itself. Through this long interval of three centuries a foreign literature prevailed—that of the Church of Rome, with its Latin and its legends—the ingrafted tongue having no root in the spirit of the people, but remaining a mere life in death.

From this judgment we must except Saxo Grammaticus and his *Historica Danica*, which, though written in Latin, was written whilst the old Scandinavian knowledge was in its fulness. Saxo was contemporary with Snorre Sturleson, had the famous sagaman, Arnold, the Icelfander, who, like himself, was in the service of Absalon, archbishop of Lund, for companion, and drew, according to his own confession, his earliest annals from the Eddaic songs, Runic inscriptions, and the written records of the Icelfanders. He completed his *Annals* in 1186, merely enshrining in Latin what had drawn its life-blood from the vigorous vernacular. No wonder, then, that he could supply such material for the genius of our Shakespeare and the Danish later writers. But from him and his contemporary chronicler of Norway, Theodoric, the monk, what a dreary dearth till the very commencement of the seventeenth century compared with the Anglo-Saxons, who adhered longer to their own tongue, had their 'Song of Cædmon,' their fine poem of "Beowulf," "The Battle of Finsburgh," and the "Song of the Traveller." But when we have taken leave of Saxo, Theodoric, and Svend Aagesen, author of the *Suenonis* in the twelfth century, with the exception of a treatise on medicine by Henrick Harpestreng, in the thirteenth century, we travel down to the fifteenth before we reach the *Rumkronike*, or *Chronicle in Rhyme*, of Neil, a monk of Sorø. Neil turned Saxo's Latin into Danish, and added fresh matter from other sources. Soon after Mikkell, a priest of Odensee, produced a volume of religious poems; but these were solitary swallows who made no summer. In 1479 the university of Copenhagen was founded, but seemed only to add to the rage for Latinity. The learned wrote in Latin; the court spoke German. In 1508, Peter Lolle published a volume of *Proverbs* in Danish; and in 1550, the Bible and New Testament, under the influence of the German Reformation, were translated into the native tongue. In 1591, Vedel published the first volume of the *Kampe-Visor*; yet these great events, capable, one would have thought, of stirring the popular mind to its depths, appeared for a long time to produce little effect on native literature.

The first man who may be said to have heralded the dawn of modern literature was Anders Christensen Arreboe. Arreboe was bishop of Drontheim at the early age of thirty; he died in 1637. His chief work is the *Hexamæron*, or, *the World's First Week*, written in Alexandrines, the same stanza as that of the German *Nibelungen Lied*. It is a free translation, or rather adaptation, of *The Creation* of Du Bartas, which was recommended to him by the chancellor Christen Friis. It was completed in 1622, but not published till after his death. The poem is a compendium of all the natural philosophy of his time. It abounds with learning, and displays great poetical beauty. The Danes regard him as the Chaucer of their literature. In the Swedish literature Stiernhelm holds a parallel place, though he wrote a few years later, and in a more polished language, that of the court of Christian IV., brother-in-law of our James I.

Anders Bording, who immediately succeeded Arreboe, was a lyrical poet of considerable merit. He was born in 1619 and died in 1677.

Scandinavian literature.

Thomas Kingo was a man of far higher and more serious genius. He was born in Slangstrup in 1634, and died in 1703. Kingo was of Scottish descent, his grandfather having gone to Denmark after our Scottish James married the sister of Christian IV. He was a genuine religious poet; he wrote a volume of hymns, which at once acquired an immense popularity and were translated into German, Swedish, Icelandic, and Latin. These are still in use, and highly esteemed by the people.

The other poets of this period were the patriotic William Helt, who died in 1724; the satirist, Tøger Reenberg, who died in 1742; and Jörgen Jorgenson Sorterup, who wrote both satires and *Hellesange*, or martial songs. Christian Falster was also a most stinging satirist, whose productions appeared between 1730 and 1750.

Denmark at this era also distinguished itself in various other departments of literature and science. History and natural history flourished. Ersk Pontoppidan, born in Funen in 1616, and bishop of Drontheim in 1678, published his *Grammatica Danica* in 1668, being the first systematic analysis of the Danish language. In this department he was followed by Peter Syv in 1685, and Hoysgard in 1743. The second Pontoppidan, also Erik Pontoppidan, but much more celebrated than the first, is well known in England by his *Natural History*; but he was the author also of various other learned and important works, as *Annales Ecclesiæ Danicæ*; one on historical geography, *Marmora Danica*; natural history, *Gesta et Vestigia Danorum extra Daniam*; one of the first theological romances, *Menoza*, &c. &c. He was born in Aarhus in 1698, and ascended through various ecclesiastical dignities till he became bishop of Bergen and chancellor of the university of that city.

In theology, also, Hemmingius flourished at this period; in jurisprudence, Theophilus and Seavenus were most eminent; in medicine and physiology, Morsing, Ole Worm, better known by his Latinized cognomen, Olaus Wormius, also celebrated for his works in history and antiquities; Simon Pauli, Bartholin, and Olaf Borrich. In philosophical knowledge A. Krag, Eilschov, and Peter Severin; in mathematics, O. Römer; in philology, Winding and Rhode; in history and literature, Hvitfeldt, with his *Kronike*, Resen, Gram, and Arnas Magnæus. A lady also, Brigitta Thott, distinguished herself by the translation of Seneca and Epictetus. These are evidences of a rapidly growing wealth of intellectual accumulation. But the great man of this epoch was Denmark's most illustrious astronomer, Tycho Brahé, whose life and discoveries will be found under their own head.

Brahé introduced to notice another astronomer, namely, Christian Severin Longomontanus. Longomontanus was a poor orphan, who being educated by the minister of his parish, attracted Brahé's notice at the college of Wiborg. He took him and instructed him in astronomy. Longomontanus went with Brahé during his exile to Prague, but on the death of his patron returned, and became professor of the higher mathematics in Copenhagen. He was more brilliant than sound; he believed in astrology, and that comets portended disaster. He died in 1647.

Holberg. The appearance of Holberg is regarded by Denmark as a great epoch in its literary history. He is their great comic poet, the Moliere of Denmark. Arreboe and Kingo were writers to be proud of as pioneers, but not to claim comparison with the authors of other nations. To that distinction the Danes believe Holberg fully entitled. Still he has no claims to the tragic; he is simply comic and satirical. He has no Macbeths, no Othellos, Hamlets, or Romeo and Juliets; but the Danes see all their social life, their humour and national character so clearly reflected in him, that they are never weary of their exhibition. He became at once universally popular through a satirical mock-heroic poem called *Peter Paars*. In 1722 appeared his

Scandinavian literature.

Mikkelsen's Four Comic Poems, and, in 1726, his *Mikkelsen's Metamorphoses*. He then began writing for the stage with amazing rapidity and equal popularity; and saw acted and published seven volumes of plays called *Mikkelsen's Comedies*. These were speedily translated into Swedish, French, and German. He thus became the founder of the comic stage of Denmark. His *Niels Klim's Subterranean Journey*, a satirical work in Latin, was equally popular, and was translated by Baggesen and others into various languages. He wrote many other works on ecclesiastical history, a *History of the Jews*, biographies in the style of Plutarch, *Moral Tales*, &c. He died in 1754.

From the death of Holberg to the publication of *Rolf Krage* by Evald, the next poet who marked a national era, the only names of note which appear in the history of Denmark's literature, are those of Stub, Sneedorf, Tullin, and Stenersen, and these are of a minor class compared with Holberg. It is curious how common-place abounded in most European literature of this period. The compositions of Ambrosius Stub consist of lyrics and drinking songs, written in the deepest poverty and obscurity. He was born in Ribe in 1707, and passed the greater part of his life in Funen, where, while his songs were on every tongue, he himself continued in the most perfect neglect. He is said to have died in 1758. His merry drinking song, "Crambambuli," is still everywhere sung by the Danish and German students.

Christian Brauman Tullin, with far less talent, had a far different fortune. He was in easy circumstances; fame attended his every effort; and everywhere he was received with open arms as a genius of the highest order. When we look in the poems which could thus entrance his contemporaries, we find them to consist of odes, prize poems, occasional verses, epitaphs in large numbers, on a par with the verses to Cloe or Cleanthe, which fill so many volumes on English shelves once called poetry.

Peder Christoffer Stenersen was a clergyman and comic poet, who died in 1776. Jens S. Sneedorf, who lived at this period, was the father of the periodical literature of Denmark. His poems were much admired, but his *Patriotic Spectator* was still more popular, and undoubtedly did more than all writings which had gone before to refine and elevate the public taste. About this period, too, Kraft, Langebek, and Mollman distinguished themselves; Kraft in logic and metaphysics, Langebek in periodical literature, and Mollman in history.

Evald. "About the middle of the eighteenth century," says Molbeck, the great Danish critic, "there stood forth a young man whose destiny it was to give to the poetry of Denmark a wholly new form." This man was Johannes Evald, the son of a clergyman, the director of the orphan-house in Copenhagen. Evald was born in 1743, and died in 1781, in the thirty-eighth year of his age. He was unfortunately intemperate in his habits, having been disappointed in love. A considerable portion of his life was passed in the deepest poverty, and the most excruciating agonies from rheumatism; yet whilst almost wholly disabled for bodily motion, he struck out a new and brilliant path as a lyrical, dramatic, and romantic poet. His first successful production was a lament for the death of Frederick V. His most splendid lyric was "King Christian," which became the national song of Denmark. Evald was equally great as a dramatist, in the satirical drama, in tragedy, and in opera. Excited by the *Messiah* of Klopstock, he burst the fetters of the French taste, and overthrew the Frenchified tragedies of Nordal Brun and Niels Krogh Bredal, imitators of Voltaire. His *Adam and Eve*, his first production in the romantic school, was the first original tragedy in Denmark. His next, *Rolf Krage*, drawn from the heroic times of Denmark, opened up that rich field of myth and legend which Oelenschlager has since so splendidly

worked out. This was followed by *The Death of Balder*, his most noble production, in which his admiration of Shakspeare and Ossian are clearly marked. His lyrical drama, *The Fishermen*, was his last work of any extent.

Scandinavian literature.

DANISH LITERATURE FROM EVALD TO BAGGESSEN.

The forty years from the death of Evald to that of the death of Baggesen produced a great number of poets and literary men in Norway and Denmark, but none who rose to the same national rank; we must, therefore, pass slightly over them. At this period the literary men of Copenhagen, a large proportion of whom were from Norway, introduced club-life, in imitation of that which had in England flourished under different chiefs, and where Dryden, Pope, Addison, Gay, Bolingbroke, and, in fact, all the principal literary men had assembled, or still did assemble. The Norwegians formed themselves into a club, called the Norwegian Society, which met at Juel's coffee-house, in the Svartegaden; and at its head stood John Herman Wessel. The Danish club, at the head of which stood Evald, met at Neergaard's coffee-house, in the Badstuestaden. Another club, consisting of men who could not go the length of the hostilities of these two rival clubs, formed under the title of the Society of Belles Lettres.

Wessel, the head of the Norwegian club, was born in 1742, in the parish of Vestby, in the diocese of Aggerhuus, in Norway, where his father was dean and parish-priest. He was the nephew of the brave Admiral Wessel, called Tødenskiold, mentioned in Evald's national song, *King Christian*. In 1772, Wessel suddenly became popular by a satirical comedy in ridicule of the French trash of Bruun and Bredal, already mentioned, called *Kærlighed uden Strømper*, "Love Without Stockings." Wessel wrote a great quantity of articles in verse and prose, very much of the character of *The Three Warnings*, *The Three Black Crows*, of our own literature of that period. He edited a periodical with the singular title, *Votre Serviteur Otiosus*, and passed his days at different coffee-houses and taverns, amusing the people with epigrams and impromptus. He died in 1785, at the age of forty-three, leaving not enough to pay the expenses of his funeral.

Cotemporary with Wessel were Johannes Wibe, a comedy writer; Bull, the author of ethic and didactic poems; and the brothers Trøjel. Peter Magnus and Peter Kofod Trøjel, both writers of bacchanalian lyrics, and the latter of some serious poetry.

Edward Storm, a Norwegian, is the author of *Bræger*, a mock-heroic poem, describing a rural dean going his rounds at Easter, collecting his pask-eggs; also of narrative poems and fables of the Fontaine school. His ballads and religious poems have great merit.

Tyge Rothe was more noted for his prose than his poetry. His work on *The Love of One's Country* is a fine specimen of prose style. Johan Nordal Brun, whose French tragedy we have noticed, was in his time very popular; but his fame has long died out, except as connected with the violent contest which his tragedy excited. He received church preferment, became a truly eloquent preacher, and wrote a poem, *Jonathan*, in ten books,—an utter failure. He died in 1816.

In this period also appeared several ladies of considerable merit in poetry and the drama: Dorothea Bichl, Catherine Bøje, Sophie Buckholm, and Louisa Lindenkron; besides several other male poets who claim only a mention: Wivert, Weyer, Fasting, and Colbiørnsen.

About the same period appeared writers whom we only need name. Povel Dankel Bast wrote poetry and epigrams; J. C. Tode, a German, who wrote as a Dane, distinguished for comedies, fables, and humorous pieces; Thomas Christian Bruun, author of tales and satires; Lauritz Hasse, a novelist; Olufsen, author of a comedy called "Gulddaasen;"

Scandinavian literature.

Horrebow and Abrahamson, poets, and the latter distinguished in other works; Samsøe, author of a popular tragedy called *Dyvecke*. Jonas Rein wrote a tragedy entitled *Hagen and Valborg*, founded on the old Danish legend of *Axel and Valborg*. He wrote also lyrical, elegiacal, and narrative poems. Thomas Thaarup wrote two admirable operas, "The Harvest Supper," and "Peter's Wedding." Thaarup was eloquent as an orator, and wrote many beautiful hymns and other lyrical poems. Zedletz, a clergyman by birth, a Norwegian, lived chiefly in the country. His poetry is celebrated as extremely varied, new, genial, and joyous, never serious and pathetic.

Christen Henriksen Pram was a man of great importance in his day. He was a Norwegian; a man in office. His principal work is "Starkodder," a heroic poem, celebrating a great mythic hero of Norway with twelve arms, the Biarnæs of the North. Starkodder is the "Kehama" of Scandinavia; and, indeed, the genius of Pram very much reminds us of that of Southey. There is the same incessant industry exerted on all sorts of topics, poetry, criticism, politics, political economy, journalism, and the literature of the day. There is the same want of penetration into the depths of poetry in its most psychological character, and, as if to seek compensation for the defect, a letting loose of the imagination almost reinless into the world of phantasy and supernatural legend. Pram also edited a periodical, *The Minerva*, in which he was succeeded by his friend, Rahbek.

During this period Luxdorph distinguished himself in criticism; Suhm wrote his *History of Denmark*, a great and elaborate work, in sixteen volumes quarto. Birknir distinguished himself as a classical prose writer; Juul as a portrait-painter; Wiederveld as a sculptor, the master of Thorwaldsen; Jacob Baden in philology; and G. L. Baden in criticism and by his *History of Denmark*.

Ove Høegh Guldberg was a great name at the close of the eighteenth century. His historic productions are master-pieces. He united with Sneedorf, Schytte, and others, in a *History of the World*. He translated the New Testament, and published an essay on the dates of the writing of its different books. But he is equally remarkable as the successor to the ministry of Denmark on the fall of Struensee, and the simultaneous ill-treatment of the amiable Caroline Matilda, the unhappy sister of our George III. The son of Guldberg, Frederick Høegh Guldberg, was a genial poet and translator of Tibullus, Terence, and Plautus. Jørgen Zoëga is celebrated for his work on Egyptian antiquities; Thorlacius for northern antiquities and literature; Abrahamson, a military officer, for his publication, with Nyerup and Rahbek, of five volumes of *Select Danish Verse of the Middle Ages*. Thomas Bagge wrote on astronomy and mathematics; and Foersom is celebrated for his translation of Shakspeare, as far as four volumes, Captain Wulff completing it in five more volumes in 1825. Before this, Niels Rosenfeldt had translated *Macbeth* in 1787, and two other volumes of Shakspeare's other plays in 1792. Bastholm requires mention in philosophy and morals, Malling in history and biography. Periodical literature had now several active and influential organs.

Jens Baggesen. Baggesen is a man who occupies a large space in the field of Danish literature. He lived partly in the last century and partly in this, and represented in the fullest manner the spirit and character of the past. He may be said to be the last of the classical school, living to do battle with and fall before the new or romantic school. In these circumstances he was accompanied by his friend Rahbek, who was the representative of the literary men of the latter end of the eighteenth century, as he was of the men of genius. He died in 1826, Rahbek in 1830. A new race and a new spirit were rising around them, even while they were in the prime of their years and popularity; but they themselves resisted vigorously the new influences,

especially Baggesen. Their cotemporaries were preparing, and some of them carrying out, as great a revolution in literary taste as that of France was in political philosophy. Klopstock, Burger, Voss, and Wieland, in Germany, had already broken down the boundaries of what was called the old classical school; Rousseau and Voltaire, in France, Bishop Percy, Burns, and Campbell, in England, had entered on an entirely new track; and everywhere giants were showing their heads above the crowd, prepared to astonish the world with a wholly novel creation,—a wholly new world of poetry, literature, and romance. Schiller and Goethe, Tieck, Fichte, and Jean Paul, Scott, Wordsworth, Coleridge, and Southey, had produced some of their masterpieces before the representatives of the last age had disappeared from the scene; and still nearer home, Oelenschläger had startled them as by the apparition of their own Thor, before the blows of whose hammer all the artistic creations of the more cold and precise French classicality fell in dust and fragments.

No man in Denmark, up to a certain moment, ever enjoyed so great and universal a popularity; his genius was so brilliant, so multifarious, so genial, and fascinating. In classical style, in learning, in wit, in imagination, in masterly reason, he was equally pre-eminent. He was the Tom Moore of the very highest classes, caressed, and living in familiar equality with princes, princesses, and nobles, with more than Moore's genius and intellectual stamina. Before he was twenty years of age, a volume of *Comic Stories in Verse*, appearing the same year as Pram's *Starkodder*, Bartholm's *Liturgy*, Scheel's *Theatre of War*, and Pram and Rahbek's new periodical, *The Minerva*, notwithstanding rose far above their interest, and placed him on the pinnacle of fame, especially in the realm of comic and satiric poetry. From this time, for nearly thirty years, he continued to pour out a series of volumes of poems, travels, dramas, operas, and miscellaneous writings, which held his countrymen in entrancement. The works of Baggesen in Danish fill twelve volumes, exclusive of his works in German, amongst which latter are some of his most considerable productions, as the *Parthenais*, *Oceana*, *Adam and Eve*, and *Heideblumen*. Amongst the Danish dramas and operas, the chief are *Holger Danske*, *Erik Eregod*, the *Trylleharp*, the passionate and very beautiful drama of *Pandion and Dione*, from the Greek mythology, and *Thora*. The poems of Nanna, written in his latter years, are undoubtedly amongst the most beautiful compositions in Danish. The translation of Holberg's *Niels Klim* into Danish is a masterpiece, and his *Labyrinthen*, containing his travels, have all the brilliance, vivacity, and fascination of a novel. His life was indeed a romance. His birth was in poverty; his youth amid the warmest sunshine of fame and honour; his latter days plunged in gloom by envy of his younger contemporaries, and a public neglect too much merited by his conduct. He died at Hamburg in October 1826.

Knud Lyne Rahbek was author of plays, songs, miscellaneous poems, prose stories, much criticism, &c. He has left, however, no original works which can fix his name pre-eminently in the temple of his country's fame, but a mass of able and interesting writings, so mixed up with the people and the time that they form an inseparable portion of the Danish literature of the period. He was born in Copenhagen in 1760, and died in 1830. He united with Nyerup and Abrahamson in the collection and publication of the *Kiempe-Viser*; edited the plays of Holberg and others; wrote the lives of his contemporaries; and songs, the favourites of the young throughout Scandinavia. He edited the *Minerva* after Pram left it, and the *Tilskuer*, or *Spectator*, in imitation of Addison's *Spectator*, for many years. Later, he edited a political paper, *Dagen*, the *Day*, from 1811 to 1814. His house, known to all Scandinavia

Scandinavian literature.

Scandinavian literature. as the Ballehuus, or house on the Mount, was the constant resort of the learned and the happy, and the home of the poor and sorrowful. He was the constant friend of struggling merit.

Oelenschläger, the greatest poet of his country, and at a time most capable of developing his genius to perfection, requires no mention here, his life and works appearing under his own name. The only writer in Scandinavia with whom he can be compared is the Swedish poet Tegnér. Both are poets of a high order and of kindred genius; but while Tegnér perhaps excels Oelenschläger in tenderness and delicacy of feeling, Oelenschläger certainly transcends Tegnér in vigour, and in the wide and varied field in which he exerted it. *Frithiof's Saga* stands as the only great poem of Tegnér, without which he would be reduced to the simple rank of a lyrical poet; but Oelenschläger is the author of a host of works, epic, dramatic, and lyrical, which, from first to last, display the same wonderful freshness and vigour. Oelenschläger's great companions at the university were the two brothers Oeisted, afterwards so famous; Hans Christian, the great natural philosopher, author of *The Soul in Nature*; and Anders Sandøe, the great lawyer and statesman.

Nicolai Frederik Severin Grundtvig is equally remarkable as a philological antiquarian and translator, and as a theologian and preacher. He was born, in September 1783, at Udby, in South Zealand. His earliest works were on the mythology of Scandinavia, of which he was an enthusiastic admirer. On this subject he published his *Northern Mythology*, and *Scenes from the Fall of the Kampe Life in the North*. But his mind suddenly took as enthusiastic a religious turn, in which he condemned his zeal for the old mythology, and in an essay *On Religion and Liturgy*, he called for reform in the church. For eight years he lay under the clerical ban. During this time, however, he employed himself in historic and antiquarian labours; published a *Bible Chronicle*, *The Roskilde Rhyme*, *Roskilde Saga*, *Kvadlinger*, &c. In 1822 he completed his greatest and most laborious work, his translations of *Saxo Grammaticus* and *Snorre Sturleson*, in six quarto volumes, by which the ancient chronicles of Norway and Denmark were made the property of the multitude. He had now also gone deep into Anglo-Saxon, and already, in conjunction with Rask, had published a masterly translation of *Biowulf's Drape*. From 1828 to 1838 he edited a monthly theological magazine, published several volumes of his sermons, and in 1829 he came to England, to consult the Anglo-Saxon manuscripts in Exeter and in the British Museum. Whilst here, he issued the prospectus of a most gigantic work, a *Bibliotheca Anglo-Saxiconica*, which was to contain not only *Biowulf's* poem, with an English translation, but Caedmon's celebrated paraphrase of the first book of Moses, many minor Anglo-Saxon poems and fragments, Layamon's Old English *Rhyme Chronicle*, in three volumes, and a collection of Anglo-Saxon homilies in three other volumes. In a second visit to this country in 1831, he explored the Anglo-Saxon manuscripts at Cambridge, where he was introduced by Mr Babbage. But though Grundtvig received much courtesy in this country, his great plans received no real encouragement. Since then, Grundtvig has become one of the most celebrated preachers and sacred lyrists in Denmark.

Steen Steensen Blicher is one of the most original poets and romance writers of Denmark. He was a clergyman, born in Jutland in 1782, who had lived in a country of wild heaths, sandy and heathery, and amid pine woods, studded with ancient cairns, and his poetry and his romances breathe their solitary and dreary spirit. Besides his tales, the earliest of which was his *Rural Dean's Diary*, and his poems, the earliest volume of which was styled *Snowdrops*, he translated *Ossian* and *The Vicar of Wakefield* from the English.

Bernhard Severin Ingemann is the great romance writer of Denmark. He has, indeed, poured forth works of many different kinds with an astonishing prodigality, and is one of Denmark's most voluminous writers. Poems, great and small; psalms, hymns, and other religious lyrics; lyrical poems of various kinds; poems, epic and dramatic; tragedies, comedies, satires. But his great historic romances are what give him his position of one of the greatest writers of his country. They are read and re-read by the winter firesides throughout the North, amid the wildest mountains and the vastest snow-barricaded woods, in the huts of the peasant, the hunter, and the fisherman.

Johan Ludvig Heiberg, a poet, critic, and dramatist, is most distinguished for the introduction of the vaudeville into Denmark, and for a new kind of play, the romantic or fairy comedy, of which the *Elves*, acted in 1835, and the *Fata Morgana*, in 1838, are amongst the most popular. In 1849, he was made director of the theatre for his services to the drama.

Madame Heiberg is one of the most distinguished actresses in Denmark. After all, the most charming compositions attributed to Heiberg are, *Tales by the author of Every-Day Stories*; which, however, by others are attributed to his mother, the Countess of Gyllembourg. Heiberg's father, Peter Andreas Heiberg, was also a dramatic and satiric writer, but rather French than Danish, being an exile residing in Paris from 1800 to his death.

Amongst living writers of Denmark, the following are of high distinction. Johan Carstens Hauch, a lyric, dramatic, and romance writer. He was born, in 1791, in Friederikshald, the son of a man of high note. He was himself chiefly attached to literature, and had been professor in Kiel and lecturer to the academy of Sorø. In his poetry there are strong traces of the naturalist, as in his *Life of Plants*. So also his romances, as *Wilhelm Zabern*, *the Goldmaker*, and *The Two Points of View*. In his tragedies, which are numerous, on the contrary, there is an equally strong tendency to metaphysical philosophizing, to the tracing out the springs of action, yet mingled with intense passion and scenes of exciting peril. They are more calculated, indeed, for the deep thinker than the seeker of light amusement.

Henrik Herz is one of Denmark's most brilliant poets and dramatists. It is in the latter character, however, that he is most distinguished. He was born in 1798, and in 1827 produced anonymously the play of *Herr Burchhardt and his Family*. Since then his principal productions have been, *The Flitting Day*, and *Emma*, plays; *Love and Police*, *Love's Strokes of Genius*, and *Debates in the Police Friend*, vaudevilles; *Svend Dyring's House*, a romantic drama in five acts; and *The Swan-Coat, or Swan Disguise*, a romantic play, in three acts, founded on the ancient sagas and viser. His most celebrated production, however, is his lyrical drama, *King René's Daughter*, ably translated into English by Theodore Martin.

Frederik Paludan Muller is one of the most powerful poets of the present day. He was born in 1809, and is regarded by his admirers as the Byron of Scandinavia. He has published *Four Romances*, *Dandserinden*, a female dance or serio-comic poem; *Cupid and Psyche*, a lyrical drama, and various other poems, lyrical and dramatic; but his great production is *Adam Homo*, a poem in three volumes.

Christian Winther, is the half-brother of Paul Martin Møller, also a poet of good standing. He is author of some novels, and of strong and life-like poems from the old *Kampe-Viser*, and the life of the people.

Caspar Johannes Bojë is a clergyman, famous for his psalms and hymns, to be found in all collections. He has published also the following tragedies:—*Svend Grathe*, *King Sigurd*, *Queen Jutta of Denmark*, and *Erik the Seventh*. He has issued a volume of psalms translated me-

Scandinavian literature.

Scandinavian literature.

trically from the Hebrew, under the name of *David's Harp*, and *Spiritual Poems and Songs*. He is also well known as the translator of Walter Scott's best romances, and as co-editor of Baggesen's works.

Hans Christian Andersen is well known to the English reader by his romances of *The Improvisatore*, *O. T.*, and *Only a Fiddler*, and his *Stories and Legends for the Young*, first introduced to us by Mrs Howitt. He was born in 1805, the son of a shoemaker in Odensé, and has raised himself to a first place in Danish literature by his talents.

To this illustrious list we could yet add a long series of names well known and honoured in Denmark. Amongst them Hans Peter Holst, who has published poems and romances; *Out and Home*, or his travels; *Giachino*, a play; and in the war of Holstein in 1848 stood prominently forth as a patriot in his *Little Hornblower*. Moritz Christian Hansen, the author of various dramas, novels, tales, and educational works. A. M. Goldschmidt, the editor of *Corsaren*, the Danish Punch, and author of *Jacob Bendiscon*, *the Jew*, a novel, &c.

Besides those who belong more particularly to the literature, poetry, and romance of Denmark, the departments of art, science, and antiquities boast names that deserve more mention than we have space to give. Thorwaldsen, the sculptor, belongs to the whole world, and will be found in his proper biographical niche in this work. He died at Copenhagen in 1844, aged about seventy years; and lies buried in the centre of the museum built in his honour. The best sculptor before Thorwaldsen was Wiedevelt, Thorwaldsen's master; the greatest now are Jerichau and Bissen, specimens of whose productions appeared in our Great Exhibition in 1851,—by Jerichau, "Adam and Eve," in plaster; "The Hunter and Panther," in marble: by Bissen, "Orestes," "Eros, or Love," "A Fisher-Boy Angling," and a bust of Andersen.

Amongst the best painters of Denmark are Juul, Gartner, Schütz, and others, in portrait; Horneman, in miniature portrait; Eckersberg, historical and marine painter; Dahl, Harder, Marstrand, Simonsen, Sonne, Melby, Sorensen, Møller, Skovgaard, Keirskow, and Rump, in landscape; Gebauer, animal painter; Lorenzen and Stubb, in historical portrait; Fritsch, Camradt, Martens, Jensen, and Ottensen, flower-painters; *genre* painters, Schleisner and Monnier. The wife of Jerichau, the sculptor, is a fine portrait-painter.

In music, Hartman, Ronge, and Gade, are most distinguished.

In medical science, the names of Bang, Trier, and Stien are pre-eminent. In botany, Professor Schouw.

In philology and antiquities, no nation boasts greater names than Rafn, Rask, Grundvig, Molbech, Finn Magnussen, and Warsaae. Rask is one of the greatest philologists that ever lived. A complete account of his travels in discovery of ancient knowledge, and into the origin and principles of language in Scandinavia, Lapland, Russia, Georgia, and the regions of the Caucasus; in Persia, Tartary, India, Ceylon, Iceland, Scotland, &c., of his grammar and treatises on almost all languages, would fill volumes. His invaluable collection of MSS., inscriptions, &c., now belong to the library of the university of Copenhagen and to the great Royal library.

In geography there is a name which most readers believe to be French, Malte Brun. It is, however, merely the Frenchified name of a real Dane, Malthe Conrad Bruun, who resided in Paris, was one of the founders of *La Société de Géographie*, and its secretary.

Professor Molbech is one of the northern literati whose industry astounds us. To his *Poetical Anthology* and his criticisms we are greatly indebted in this article. His great Danish Dictionary is work enough for one life; he is the Johnson of Denmark; but besides this he is the author of

a *Dictionary of Danish Dialects*; of a *History of the Scandinavians on the Throne of England*; *History of Erik Plogpenning*; editor and translator of various works, &c.

Of the labours of Thorlacius, Muller, Nyerup, Finn Magnussen, Werlauff, Simonsen, Thomson, Abrahamson, &c., in archæology and antiquities of the North, it is impossible to speak too highly. But for their individual labours, as well as those of Moniæd and Schlegel, we must refer to information under their own names.

In intellectual philosophy and theology, Denmark has a new and distinguished race of theorists, who seem by no means inclined to follow in the German fog, mist, and find-nothing school; on the contrary, they are of a decidedly Christian tendency. They have probed the German philosophy to its depths, and have drawn very different results from their psychological researches. Amongst the most eminent are C. F. Sibbern, author of *Psychological Pathology*, and *The Letters of Gabriel*; the eloquent Bishop Mynster; Grundvig, already mentioned; Martensen, in his *Anatomy of Self-Consciousness*, &c.; and the brothers Kierkegaard, in various works. Nor must we close our notice without again referring to the illustrious brothers Oersted, one the statesman, the other the author of *The Soul in Nature*, and discoverer of electro-magnetism in 1820, which has led to the electric telegraph, and other wonderful results.

MODERN LITERATURE OF SWEDEN.

The ancient literature of Sweden, like that of Norway and Denmark, was that of the common Scandinavia. Its first independent literature, like that of those countries, consisted of the Folk-Sagor and Visor, which we have given. During the middle ages the same causes which annihilated the native literature of Norway and Denmark, annihilated that of Sweden. It was the incubus of Latinity and Rome. From the time that monkery set its foot in Sweden till the Reformation shook its yoke from the soul of the people, there lay a dark and barren waste of mind in which the Visor and Sagor, circulating amongst the uneducated population, alone preserved the germ of intellectual life amid woods and hills. Other causes followed in Sweden, which retarded the revival of literature even more than in Denmark and Norway—the deep hold which the French influence and ideas gained there. Sweden, up to this moment, has never developed the same vigour and varied genius as the rest of Scandinavia. She is confessedly neither dramatic, epic, nor, till lately, at all historic. Many causes have been assigned by Swedish writers for this, into which we need not here enter; the reason given by Beskow, in his *Reminiscences of Stjernstolpe*, is sufficient. "No literature," he says, "is so poor in comic authors as the Swedish. What is the cause? The Swedes have no want of the love of fun or wit. But the first requisite for the development of comic, as of all other genius, is *freedom*, in the æsthetic and social meaning. Has no one, then, discovered that this may have had its influence on our dramatic status? The intolerably heavy æsthetic fetters have only in our own day become broken; but conventionalism, etiquette, and the daily circumstances of social life, rule with scarcely less vigour than formerly. We are too serious, people say. On the contrary, we are not serious enough. The most serious and most proud of all nations, the English and the Spanish, possess the most splendid comic authors."

The Swedish literary annalists divide the history of their literature into four grand periods. First, the romantic; second, the Germanico-Italian, or Stjernhjelm, period of the seventeenth century; third, the Gallic period; and fourth, the new school, commencing with 1809. Over all, except the last two periods, we may pass very cursorily, for the reasons adduced above. The Eddaic and Visor periods are

Scandinavian literature.

Scandinavian literature. here already given; the second and great part of the third period present nothing of great originality. The first, or romantic period, extends over the enormous space of 500 years, that is, from the introduction of Christianity, or about the years 1000 to 1600. During this time the chief literature was historical visor and folk-sagas, as the "Battle of Brunkeberg," "King Erik and the Fortune-telling Woman," "Battle of Brännkryka," "Gustavus and the Dalecarlians," "Charles XII's March," a fine song, set to a fine air, and other ballads about Charles XII., &c.

Amongst the first imitators of the old Folks-Visor was Nicolaus Hermanni, bishop of Linköping, in the thirteenth century, who wrote the ballad of "Elsif Eriksdotter, the Nun." This author, too, wrote an account of Ansgarius, the Northern Apostle. In 1437, Bishop Thomas wrote poems on Engelbrecht and Erik Puke; Dahstjerna, the "King and Sir Peter," on the victory of Narva. Director Odel wrote a popular song, "Malcolm Sinclair," and "The Old Hen-woman's Song," by Cardius, pastor of Södermanland, is the Swedish literary history from Christina to Adolf Frederick. Erik XIV., a monarch equally poetical and unfortunate, and who married Karin Mansdotter, the daughter of a corporal, wrote some most popular songs, especially one addressed to his low-born but admirable wife. Being imprisoned by his usurping brother John, he wrote in his prison religious hymns, and the versions of the 180th and 373d psalms in the Swedish psalm-book are by him; the latter one a most singularly simple and touching composition. Ericus Olai had preceded King Erik in psalmody; and others of that period followed in the same line. Many nobles of that period also wrote popular love-songs; amongst them Count John Hoya. Gustavus Adolphus celebrated his youthful favourite, Ebba Brabé; and one of his bravest officers, Colonel Ekeblad, wrote many lyrics in imitation of the ancient Visor; as "The Five Perils of Man"—from the caprice of great lords, from April weather, rose-coloured garments, cards, and fair women. He wrote also many amorous pastorals. Buæus was the first introducer of hexameters.

The reading of this period consisted greatly of foreign chivalric poetical romance, and Queen Euphemia of Norway was a great translator of them; as the Charlemagne and King Arthur romances, which were called Queen Euphemia's Visor. Then arose hosts of these, followed by "Rynecké the Fox," "The Dance of Death," "Martin Goose," and the like. The native Folks-Sagas were as numerous, besides the "Childhood of Christ," "Judas Iscariot," "Pontius Pilate," "Faust," "Fortunatus," "Owlinglass," "Baarlaam and Josaphat," "Blue-Beard," "Master Cat," and all the middle-age romances still read by the German peasantry. To this literature of simplicity and simple faith we must add that of Rhymed Chronicles, and a species of drama much akin to Mysteries and Moralities, in which all the characters of sacred history figure; and others, called Ballets, resembling the English Masques. In some of these, and especially in the play of "Tobit," by Olaus Petri, written only eight years before our Queen Elizabeth ascended the throne, we are astonished to find the wonderful resemblance betwixt Swedish and English, much greater than betwixt English and Scotch of the same period. What is remarkable is, that the sound and spelling of the *th* in "the," "three," and all similar words, now quite abandoned by Swedes and Danes, and nearly all continental nations, and so difficult of expression to foreigners, was then in full use.

SECOND SWEDISH PERIOD—THE GERMANICO-ITALIAN SCHOOL, SEVENTEENTH CENTURY.

The Reformation in Sweden, as in other countries, put to flight all the prognostics of its effects on poetic literature. VOL. XIX.

Scandinavian literature. What many authors have asserted that Protestantism is founded on reason, and is therefore opposed to imagination and poetry, soon showed its falsity. Darkness, delusion, and superstition fled, but all the elements of poetry remained in the daylight. Nature smiled with her glorious face into more intelligent eyes; into spirits more capable of comprehending and loving her. Shakspeare and Milton stand the perpetual refutations of the aspersions on Protestantism as prosaic. Here no Shakspeare arose, but the drama was removed from the cloister and the church to its more legitimate stage amid social life; and John Messenius and his son Arnold, and George Stjernhjelm, improved on what Olaus Petri had begun. The elder Messenius wrote six dramas or comedies, as all dramas were then called, like Danté's. They were chiefly from the old sagas, or the national history, as *Svanhvita*, *Signill*, *Gustaf I.* They are all flat, and destitute of interest at the present day. The younger Messenius was historiographer of the kingdom, and represented the whole reign of Gustaf I. in a drama! Their cotemporaries, Prvtz, bishop of Linköping; Brask, a clergyman; Hjärne, Kolmodin, and Beronius, all wrote plays, and terminated that school. Then followed George Stjernhjelm, who wrote dramas, lyrics, an epic and didactic poems, and produced such an impression that he decided the character of his country's literature for a century. As he chose his subjects from the classics, he has been considered the first classic poet of Sweden. His great poem was "Hercules," in hexameters, which Hammarsköld pronounces the best poem of its kind in the Swedish language. He wrote besides, "The Hanged Artild," "The Captive Cupid," &c., &c. His works much improved the language. His chief followers were Lindsköld, Rjörk, Wallenius, and Count Stenbock; but the growing influence of the Italian and German taste was now fast prevailing.

The chief writers of the Italian school were Dahstjerna, who introduced the *Ottova Rima*; Gustaf Rosenhane, Leyoncrona, Rudcen, bishop of Linköping, Gripenhjelm, and others. Of the German school, Samuel Columbus, who wrote songs and epigrams, under the title of the *Biblical World*; Gyllenborg, Holmström, Risell, Werwing, Geisler, and Olaf Broms. Lasse Lucidor, or Lasse Johansson, was a wild, eccentric genius of this period, who lived like a Diogenes, wrote songs and hymns, and was murdered at the age of twenty-four. The first lady authoress of Sweden, if we except Queen Euphemia appeared in the person of Fru Brenner, who bore fifteen children, and wrote still more poems. Her verses related chiefly to weddings and funeral feasts, and had the strangest and most elaborate titles; but she was immensely popular in her day, and was complimented by more than thirty eulogistic addresses, some of them from foreign countries. Archbishop Haqvín Spegel was the Arreboe of Sweden. He translated, and, the Swedes say, greatly improved Arreboe's *Hexameron*; but his psalms are the compositions which give him, and justly, as the Swedish Psalm Book testifies, his reputation in Sweden. He had read Milton, and wrote a *Paradise Lost and Found* of his own, as also a keen satire, called *Sir Highmand Downfall*. His disciples in the department of sacred poetry were Olof Kolmodin, author of the immensely popular *Voice of the Dove*; Professor Arrhenius, Bishop Svedberg, and Jacob Frese. Besides these, Runius, Dalius, Triewald, and Fornelius, are names of mark of this era.

The taste and knowledge of Sweden were now fast progressing, and they were growing familiar with the best French, English, German, Italian, Dutch, and Danish authors. We find them quoting Ronsard, Corneille, Spenser, Milton, Cowley, Flemming, Cats, Vondel, Arreboe, Kingo, Hoffmanswaldan, Lowenstein, Opitz, Gryphius, Guarini, Boileau, etc.

Scandinavian literature.

THE EIGHTEENTH CENTURY—THE FRENCH SCHOOL.

The splendour and *eclat* of Louis XIV.'s court, and the familiarity with French affairs and opinions produced by the long war betwixt Popery and Protestantism, which was ended by the peace of Utrecht, spread everywhere French taste and fashion. Even England, which had so stoutly combated French domination, did not escape its contagion. Our literature, from Pope to Cowper, bore melancholy traces of it; Germany suffered immensely from the same cause; and a fresh importation of the Gallo-mania was revived in Prussia by Frederick, miscalled the Great, where Voltaire and French fashions, French vice, French atheism, and French poetry were enthroned and worshipped amid pigtailed, powder, and jack-boots. But in no country did this Gallic pest fall more heavily than on Scandinavia. The Swedes divide this period into three portions:—

1. *The Morning of Gallicism—The Dalin Period.*

The principal writers of this period are Dalin, after whom it is named, Fru Nordenflycht, Creutz, and Gyllenborg. They display little originality, and there is as little pleasure in perusing their compositions as there is in those of our own Yaldens, Spratts, Dukes, and the like. Dalin was a courtier and a favourite of Queen Louisa Ulrika. He wrote an epic, *Swedish Freedom*, a drama, *Brynhilda*; a comedy, *The Envious One*; a great number of festive odes, birth and death poems, &c. In fact, he filled all the functions of a court laureate, in effusions which have no more value for posterity than so many old cast-off clothes. As a prose writer he had more merit, publishing a periodical, *The Argus*, in 1732, on the model of Addison's *Spectator*, which continued two years.

Hedvig Charlotte Nordenflycht was a very different person. She was the popular poetess of this period, and in a better age would have been a better poetess, for she possessed, in no ordinary degree, passion, feeling, and imagination. She vented her real and her Sapphic sorrows in a series of elegies called *The Sorrowing Turtle Dove*. She wrote an idyll, *Camilla*, and much love poetry. She was the centre of all literary society, and founded a literary society, of which the queen, Louisa Ulrika, seized the idea, and established the Academy of Literature, which lasted till her death in 1782, and was again restored by her son, Gustavus III., in 1786, under the title of the Academy of Literature, History, and Antiquity.

The Counts Gyllenborg and Creutz were formed in the school of Madame Nordenflycht. Creutz was born in Finland in 1729, and died in 1785. His best work is *Atus and Camilla*. The only merit of the poem is its feeling for nature, and its beautiful style. He wrote also a *Song of Summer*, elegies, and a clever satiric poem, *The Defence of Lying*. Gyllenborg's chief works are, *Songs of the Four Seasons*—for both he and Creutz had an admiration of Thomson's *Seasons*; *the Joys and Sorrows of Men*, *Ode on the Power of the Soul*; fables, satires, and plays. His *Tåget öfver Balt*, in twelve books, is a feeble attempt at a national epic, in the style of the *Henriade*. In most of his works there is a melancholy without hope, a poison of scepticism. He was the chief poet of his time, and his poems on the Seasons the most pleasing.

The other writers of this first section of the century were Wrangel, Hesselius, Celsius, Lalin, Wellander, dramatists; Liljestråle, Skjöldebrande, Göstafsson, Bergström, narrative poets and translators; Olof Rudbeck, Livin, Cederhjelm, Nyrén, comic and satiric writers. Mörk was the great romance writer of the time, Sweden's first regular author of romance. His models were Fenelon, Barclay, and Lohenstein; yet his productions are more numerous than readable. He had imitators in Wexel and Gyllenstolpe. Palmfelt and Nicander were translators from Virgil and others.

2. *Noon of Gallicism—The Period of Gustavus and the Scandinavian Academy.*

Gustavus III. was a great patron of literature and an author himself, but unfortunately educated in the French taste, and thus only contributed more firmly to fix that taste on his country. Still, in some respects, Swedish literature owes much to Gustavus. He encouraged polish of style, and discouraged coarseness and grossness. Of this mid-day of the Gallic era, Gustavus, Kellgren, Leopold, and Oxenstjerna are the chiefs. Gustavus, following in the steps of his mother Ulrika, and by the advice of his tutor Tessin, established the Swedish Academy of Literature in 1786. He wrote a number of dramas, the chief of which are *Gustavus Wasa*, *Gustavus Adolphus* and *Ebba Brahé*, *Siri Brahé*, *Helmfelt*, *Gustavus Adolphus's Marcmarmar*, *Frigga*, a comedy; *The Jealous Neapolitan*, *Alexis Michalovitsch*, *Natalia Narischkin*, &c. These dramas were in prose, and are still read with interest; but he had several of them thrown into the form of operas by Kellgren and Leopold, by which they only lost their freshness and originality, and the prose ones are still preferred. Kellgren was born in 1741 and died in 1795. He was the best lyric poet of the period. He commenced the *Stockholm Post* in 1777, with his friend, Carl Lenngren, which exercised a powerful influence for nearly fifty years. He was a witty and keen satirist, as is evidenced by his *Enemies of Light*, *My Laughter*, *Man only a Genius when Mad*. He wrote operas which did not equal his lyrics. Kellgren showed unmistakably symptoms of a tendency to back out of the bondage of the French school. On studying the German literature, he began to suspect that his literary career had been an error; and on reading Klopstock's *Messiah*, he declared that he had lived in vain.

Carl Gustav Leopold, after the death of Kellgren, was at the head of the literary world of Denmark during the remainder of the century. He was born in 1756 and died in 1829. His works fill six volumes, including almost every species of poetry but the epic; but he is best known by his dramas and miscellaneous poems.

Johan Gabriel Oxenstjerna, born in 1750, became a marshal of the kingdom, and died in 1818. He was a wonderful admirer of our Thomson, and wrote in imitation the *Harvest*, and the *Hours of the Day*, which, spite of the faults of the age, display living pictures of country life in Sweden, much idyllic beauty, and homely, attractive grace. He also translated Milton and Tasso; the first remarkably well, the latter indifferently.

The other writers of this period are Johan Stenhammar and Isaac Blom; Axel Silverstolpe; Sjöberg, who cultivated the English taste; Edclcrantz, who translated "God Save the King."

TERMINATION OF THE FRENCH SCHOOL IN SWEDEN.

This was properly a transition period. The day of French taste was drawing to an end. The French Revolution, by its startling events, was in fact most powerfully destructive of French taste. Voltaire, the author of the miserable *Henriade*, by his other writings was preparing a mine which, in its explosion, broke the intellectual fetters of other nations. In England, the process of literary revolution dates still earlier, from Bishop Percy's *Reliques*, in 1765. In Germany, similar innovations date from Klopstock; in Denmark, Steffens carried about the new German fire; and in Sweden the same spirit was stirring in Bellman, Hallman, and numbers of others before the French Revolution broke out. That world-awakening carried on and completed the change. Not only Bellman and Hallman, but Kexél, Wallenberg, Lidner, Thorild, and Madame Lenngren, at this period, in songs, lyrics, dramas, and others compositions, drew their spiritual life

Scandinavian literature. from the people, and startled and exasperated the orthodox dullness of the academy.

Carl Michael Bellman is the Anacreon of Sweden. He is the pride of his countrymen and the puzzle of foreigners. His songs, which are chiefly bacchanalian and describe the people in their tavern life, have a wonderful joviality and power of language; but much of the charm of his compositions is lost to all but Sweden. There can be no translation of such lyrics as "Up, Amaryllis!" "Drink out thy glass, see Death awaits thee;" "Mark how our shadow, mark, Moitz, my brother;" "Ulla, my Ulla!" etc., etc. Bellman was born in 1740, and died in 1795.

Carl Israel Hallman wrote comedies and farces, often coarse but full of Swedish folk-life. His vaudeville of *Opportunity makes the Thief*, is still extremely popular on the stage. He drew his characters from the same class as Bellman.

Olaf Kexél lived a gay, vagabond life, and found a home in a debtor's prison. He wrote comedies, and re-wrote those of others, as *Captain Puff*, and *Michael Wingler*, which still are admired.

Carl Envalson, a writer of numerous plays, *Schröderheim*, *Lannerstjerna*, and *Holthusen*, were popular in their day. A much more remarkable writer was Jacob Wallenberg, a witty dramatic author and traveller. He wrote merry sketches on an Indian voyage, *My Son in the Galley*, or *All Sorts of Ink-horn Wares*; and an equally amusing visit to London, where he saw and described Wilks, in *London in George III.'s reign, as seen by a Swede*.

Lidner and Thorild were men of a totally different character, grave, philosophic, and almost wholly of the new school. Lidner wrote *Medea*, a tragedy; *The Messiah*; *The Last Judgment*, etc., but with a pure and a fiery glow, which denoted the coming change. Thorild was from head to foot a man of the new ideas. His nature was revolutionary. In the face of the court and academy he maintained the merits of Ossian, Klopstock, and Goethe. He was a master in prose, published a *Critique on Montesquieu*, studied law in England for two years, and in 1798 was banished for four years for a work *On the Freedom of the Understanding*. His poems, the *Göthmanna Songs*, *The Passions*, and *Pleasures of the Imagination*, have much merit. Swedish literature, in fact, is greatly indebted to Thorild for the spirit of manly freedom, and the sound principles of taste which he infused into it. Enbom and Engzell were followers of Thorild.

But perhaps the most interesting character of the close of the last and the opening of the present century in Sweden is Anna Maria Lengren. She was born in 1754, married Carl Lengren, counsellor of Commerce in 1780, and died in 1817. She commenced her literary career by the translation of some operas; but her original poems, contained in one small unpretending volume, are what will for ever secure her a place amongst the classical writers of her country. She is the Miss Bremer of Sweden in poetry. Her poems are, in fact, Swedish domestic life in all its varieties and all its charms.

Fru Widström was another lady poetess of this time, of a more sentimental mood.

Amongst other writers of the period were Paykull, Boman, Regnér, and Adlerbeth, chiefly known as translators of the classics; Stjernstolpe and Skjöldebrand, translators and original writers; Wallerius, a song-writer, the Tom Moore of his day, who was in much request at dinner and other parties for his fine voice and singing of his own songs; Choræus, Kullberg, and Lindegren, poets of a grave caste; a second Kullberg, who wrote after-pieces for the theatres; Granberg, Altén, Nordfors, Becker, and Wallmark, names of merit; and Ehrens-värd and Hóijer, men of profound philosophical merits. Ehrens-värd was an admiral, and wrote on esthetics in a deep and

original manner, on what he called the *free arts*—architecture, sculpture, painting, and poetry—because they are not based on our necessities, but spring out of the love and desire of beauty. Hóijer followed up Ehrens-värd's views by establishing a *Literary Gazette*, to diffuse ideas on art and true beauty in literature; but he was prohibited from proceeding by the king, who declared that he would only have one literary journal in Sweden, and put it into the hand of Wallmark.

THE NEW SCHOOL, COMMENCING IN 1809.

Whilst in England, Germany, and Denmark the new literature was progressing rapidly; whilst in Germany, philosophy, through Kant, Fichte, and Schelling, had acquired a profounder field of labour, more extended views of science and art, and the latter, through the works of Winkelman, Lessing, Heider, Goethe, and Schiller, became more correctly understood; and the Schlegels, Tieck, and Novalis, made the public familiar with the beauties of art in the middle ages in other towns and other countries,—the Swedish academy still contended stoutly against the new spirit of the age. Though Oelenschlager, following Evald, and stimulated by Steffens, was producing new creations of beauty in Denmark from its ancient myths; though the spirit-destroying doctrines of the French Encyclopædists had failed of its object, religion had received a new impulse, natural philosophy taken a healthier tone, history was liberated from the chains of rhetoric, and everywhere men were crying out for fact, reality, practical virtue, and freedom, the academy stood fast, resisting all innovation. Fortunately a political revolution gave freedom of the press, and effected the necessary revolution in mind. "The Friends of Literature," an association formed in Upsala some years before, including some of the leading critics of Sweden, in 1807, resolved itself into a new league called the Aurora League, and the first men of the movement flocked into it. In 1809, on the establishment of the freedom of the press, the effect of this association was seen. A new journal, *The Polyphe-m*, edited by Askelöf, was issued, which made determined war on the old school. In 1810 also appeared the *Lyceum*, and in the same year *Phosphorus*, the organ of the Aurora League, with Atterbom at its head. This journal became famous, and the disciples of the now triumphant new school eventually settled into the three sects of Phosphorists, a Romantic school, the Gothic school, and the Miscellaneous school, but all more or less of the romantic character. Two writers are considered to constitute a class of themselves: Phosphorists, yet having traces of the past school about them, amidst all their beauty and freedom, and not entirely classable with the sects which afterwards arose. These were Franzén and Wallin.

Franz Michael Franzén was born at Uleaborg in Finland, in 1772, and was educated at Abo. He travelled into most European countries, England included, and rose through different preferments from librarian to the university of Abo to the bishopric of Hernösand, where he died in 1847. Franzén resembles Wordsworth in the simplicity of his subjects, drawn from lowly life and open nature. There is in him the same wise and almost child-like nature. The Swedes have noticed the resemblance. It is the idyllic and lyric in which he is most at home. He wrote several larger works, *Emile*, or *an Evening in Lapland*, new and striking; *Columbus*, an unfinished epic; *Gustavus Adolphus in Germany*, an epic fragment in twenty cantos; *Svante Sture*, a romance in the school of Walter Scott; *Julia de St Julian*, a poetic story; *The Murder on Elgarö*, a drama, etc. But it is not on these, but on his small poems that rests his fame.

Wallin, the archbishop of Sweden, was born in 1779, and

Scandinavian literature.

died in 1839. He is the greatest religious poet of his country. He wrote much miscellaneous lyrical poetry; but they are his hymns, of which seventy-six are included in the new Swedish Psalm-book, which have given him his unparalleled reputation as a sacred poet. He is styled the "David's Harp of the North," and truly was an archbishop in song as well as in station. His hymns are more truly grand anthems and religious poems. The same characteristics marked his preaching and his speeches. His sermons, like his psalms, are said to have no parallel in the Swedish language.

THE PHOSPHORISTS.

Atterbom, Hammarskold, and Palmblad were the chiefs of this sect, but Atterbom was its head and founder. In *Polypheme*, in *Phosphorus*, and other publications, he led the attack on the academy and the old French school. But in aiming at being romantic, the new school became too romantic; they became fantastic. In Atterbom's "Island of Blessedness," and his "Flowers," we are carried back to the allegories of Fletcher's "Purple Island" and Darwin's "Loves of the Plants." His productions are warm and sunny, but want substance and reality. In the former mentioned, and in "The Blue Bird," there are splendid passages, but as wholes they are heavy. Atterbom was born in 1790. In later life he became reconciled to the academy, and grew conservative through his connection with court. The results of his university teaching are several works on history, *A System of Philosophy*; *The Swedish Seers and Poets*, etc.; amongst the latter standing pre-eminent Swedenborg and Ehrensvarld. This work, in fact, contains some of the best accounts we have of Swedish writers. His poems were published in two volumes in 1836.

Hammarskold was born in 1785, and died in 1827. Besides being one of the ablest critics and historians of Sweden, he was one of the ablest critics and historians of Sweden. His poems and tales are of little value, but his histories of Swedish literature, of the plastic arts, and philosophy, have given him great and just fame.

Palmblad besides being a very caustic critic, was the author of the first Swedish novel *Amala*, an Eastern story, of *Castle Stjernborg*, *Åreskutan*, and *The Island in the Lake of Däll*. He translated portions of Homer, Æschylus, and Sophocles.

Of this same school is Anders Fryxell, a poet, and author of an admirable History of Sweden, under the name of *Narratives out of the History of Sweden*. Adolf Iwar Arvidsson is a distinguished poet, and editor of *Early Swedish Ballads*, in 2 vols. Besides these are many names—Elgström, Ingelgren, Sondén, Zeipel, Borjeson, Rydquist, editor of Heimdall, and translator of Moore's *Irish Melodies*. Hedborn, Graftström, and the Countess d'Albedyhl, all more or less distinguished in poetry and literature. Fru Kerstin Nyberg is a popular poetess, the L. E. L. of Sweden. Her poems have appeared under the *nom de plume* of Euphrosyne.

THE GOTHIC SCHOOL—TEGNÉR, GEIJER, &c.

Tegnér and Geijer, the two greatest names of Swedish literature, stand at the head of a section of the literary world so-called, because they adopted a more general taste than the phosphorists, whom they deemed too one-sided, and condemnatory of much in the old school which had merit. They approved of the reform, but denounced the bitter spirit in which it was prosecuted. Instead of adopting what was merely national, they extended their range of sympathy over the whole Gothic race. Hence their name.

Geijer was the son of an iron-founder in Wermland. Born in 1783, he studied in Upsala, visited England in 1809, and

became professor of history in Upsala in 1817. He originated the Gothic school in the *Iduna*, and perceiving that Atterbom and the Romanticists were fast merging into German idealism, he took fresh and more solid ground. He produced some of the most admirable poems in the language on this principle, "The Last Scald," "The Viking," and "The Last Champion," in the style and spirit of the ancient Visor. He is known equally as a poet, a musician, and a historian. Like Bellman, he has written the music to many of his small poems, and some of them expressly for Jenny Lind. But his *Chronicles of Sweden*, *Svea Rikes Hufder*, are the grand monument of his fame. Sweden has many poets, but only one Geijer. He was writing also a *Lesser History of Sweden* at the time of his death, 1847. His great work, too, remains a Titanic fragment.

Elias Tegnér, the greatest poet of Sweden, was, like Geijer, a native of Wermland. His principal poems are, "Prædication or Consecration to the Priesthood," "Nat-tvarusbarnen," "The Young Communicants," well translated by Longfellow, and "Frithiofs Saga," found on the old saga of Frithiof and Ingeborg, the nearest approach to an epic poem which Sweden has yet achieved. Though not a regular epic, for it is rather a bundle of lyrical poems woven into one epic cycle, it is yet a complete and great poem. It abounds with innovations, not only every book being in a different metre, but the dramatic dialogue being introduced in the midst of the narrative. The success with which the poet has achieved these innovations prove that there is no reason in nature why poets, any more than architects, should slavishly adhere to Grecian models. We have had five or six translations of "Frithiof," none of which give any conception of the exquisite beauty and splendour of the original. His minor poems are full of beauty, life, and variety. His "Gotha Lion" is the national song, and is set to fine music.

The other chief poets of the Gothic school are Ling, Afzelius, Nicander, Von Beskow, and Lindblad, and they show the system run to ripe seed.

H. P. Ling, who died in 1839, was an eccentric man, who wrote two tedious epics, "The Asar" and "Tirfing," the former of which Lénstrom compliments as "the most long-winded poem in the language." His dramas, nine in number, are equally heavy, but his lyrics are first-rate. The choruses in his dullest dramas are masterpieces. Ling, however, is more famous as a gymnast than as a poet. He introduced the ancient classical system of gymnastics as a means of restoring the northern race to its ancient vigour, and raised it to an effective branch of medical manipulation.

Afzelius, a lyric poet of the same school, was led into the same extravagances by the overstrained admiration of the old Northern. In his own proper lyric element, Afzelius is admirable, like Ling. His most popular original poems are "The Neck's Polska," "The Neck" being a popular water-spirit of the North; and "Tomtarne," the Hobgoblins. But Afzelius has still higher claims on his country's regard. With Rask, he translated Samund's Edda into Swedish; with Geijer, he collected the *Ancient Folk-Visor*, in 3 vols.; and afterwards himself published, under the title of *Svenska Folkets Sagohufder*, a history of Sweden drawn from the traditions of the people.

Karl August Nicander, who died in 1839, was rather an Italian than a Gothic poet. Like many Scandinavians, he had a passion for Italy, and many of his poems are quickened and coloured by the South. Yet he wrote the *Rune-Sword*, a tragedy, and translated *Othello* and Schiller's *Maid of Orleans*. In fact, in Nicander there is more grace and colour than substance.

Bernhard von Beskow, besides being the author of various original poems, has produced a series of dramas, which are the nearest approach to regular acting dramas which Swe-

Scandinavian literature.

Scandinavian literature.

den possesses. The chief of these are the tragedies of *Erik XIV.*, *Hildegard*, *Torkel Knutson*, and *King Birger and his Race*. His opera, *The Troubadour*, was set to music by the present king of Sweden.

Assar Lindblad, a clergyman of Scania, is a disciple of Tegnér; his poems display much genius.

POETS BELONGING GENERALLY TO THE NEW SCHOOL.

There are a number of poets belonging to the new school, yet who differ as much from each other as they do from Phosphorists and Goths, so that they cannot be very regularly classed. Prominent amongst these are Stagnelius, Almqvist, and Runeberg, with others of more or less mark. The greatest of these poets is perhaps Stagnelius, though Runeberg treads closely in his steps.

Erik Johan Stagnelius is a genuine modern gnostic. His poetry is as fully and as positively the enunciation of gnosticism as ever were the preachings of the old Syrian and Egyptian speculative Christians. Suffering himself in a sickly and torturing body, and with a soul longing intensely for liberation, he held, with the gnostic sect, the belief, inherited from Plato and Pythagoras, that souls are here cast into prison for their past sins, and that Christ is the liberator from this captivity. All his poems, the "Cydippe," the "Narcissus," the "Bacchantes," "Proserpina," and "Svedger," are based on this faith, and are eloquent with the passion of a deep and divine sorrow. They are amongst the most spiritual poems ever written, and abound with word-paintings, that remind us of the old Byzantine pictures, with their devotional figures and golden back-grounds. Stagnelius was born in 1793, and died in 1828. Besides the works mentioned, he published *Women of the North*; *Wladimir*, a fine heroic poem in hexameters; and the *Martyrs*, i.e., *Vivia Perpetua* and her Companions, a masterly production; but they are his "Lilies of Sharon," which distinguish him from all other Swedish poets, and place him amongst the greatest intellectual poets of any country.

J. C. L. Almqvist is one of the most extraordinary characters as well as writers of Sweden. His productions are most voluminous, and on almost every subject. Professing to teach the practical duties of life, he has contrived to fly off into the strangest speculations and vagaries conceivable. Poetry, romance, philosophy, the drama, elementary treatises, and startling projects, have poured from his pen with a wonderful abundance. That he possesses real genius is undoubted, but it appears a genius allied to madness, if not to something worse. In fact, we suspect Almqvist to be a character of no ordinary kind, and his more recent proceedings put this even beyond suspicion. He has written legends of New Holland, and a life of Hector; on the condition of the poor in Sweden; on the honour of labour; and in advocacy of education. He is the champion of progress and of improvement of the social condition. He has written *Writings for the People*, *The Gospel of Health*, *The Prop of Man*, religious treatises; and along with these, others sapping the foundations of all morals, especially female ones. In his notorious novel, *Det går an*, a phrase equivalent to *Ca Ira*, he has advocated the loosest notions regarding marriage. He has written the most extravagant stories, as *Skallnova Mill*, and *Ramido Marinesco*, the infamous son of the infamous Don Juan; and the wildest fictions in his *Tornrosens Book* mingled masses of extravagance and beauty, or *Sehems-el-Nihar*, a Nubian epic; *Isidorus of Tadmor*; *the Wolf's Daughter*, &c. At one time he proposed, like Southey, a Pantisocracy, called the "New Man-home Confederacy," and set the example by going off into the primeval forests of Wernland, living in a turf-cabin, clothing himself in home-spun, and eating porridge with a wooden spoon. At length, in 1851, having robbed an acquaintance of a large amount, he poisoned

him, and got off to the Great Exhibition of London, and thence to America, to the horror and indignation of all Sweden.

The distinguished modern poets of Sweden are Vitalis, Livijn, Dehlgren, and Fahlcrantz. Livijn is also a distinguished wit, and Fahlcrantz a celebrated wit, though the bishop of Westeraås. There are also Wadman, Ingelman, Wieselgren, Bottiger, and others. But we can only devote a more particular notice to Johan Ludvig Runeberg, a Finn by birth, but who writes in Swedish, his subjects being, however, Finnish; and they bring us at once into a perfectly new field of life. Finland has its own vein of poetry, though it cannot be said to have a national literature. It has for ages existed under foreign masters; there could, therefore, be no national literature, yet it has a native poetry. Amid its solitary forests, its wide, dark moorlands, its lonely lakes, it was impossible that poetry should not visit the people under their invasions and sufferings from both climate and men. Finland has its own mythology, totally different from that of Scandinavia. There we have no longer Odín, Thor, Balder, Bragi, and the rest; but Ukko, the mightiest of heaven's powers, thunders from the purple cloud; Ahti is the god of the sea, Wellamo his goddess; Kalma, the monarch of death; and Wainamoinen, the god of song, sings through the woods and by the streams the deeds of their gods and heroes; of Kullervo, the son of Kaleva, the great ancestor of all Finnish heroes. The Finns have their songs of the maidens, of the herdsmen, of their social festivities, songs of the cradle, and of the stern and stirring passages of life. They have always had their popular poets, and sing in a metre peculiar to the country, one form of which has been borrowed by Longfellow in his song of *Hiawatha*.

Runeberg is a genuine Finnish poet; he has thrown into his poetry all the wild and melancholy character of his country, and has mingled with it a deep feeling of its sufferings and its wrongs. He indulges in no morbid feelings of his own, but he is baptized with the spirit of his country and countrymen by the reflection, over those brute but overwhelming forces of the demi-savage Muscovite, which have torn his native land as a prey from its old and cherished associations, and made it an appanage of a vast, dominant, but unamalgamated empire. These feelings break forth in the *Stories of Ensign Stål*. No Northern poet has embodied in his compositions more poetry in the highest sense,—the genuine expression of the human heart in all its joys, troubles, and passions.

Amongst the remaining poets, Wieselgren has also written a *History of Swedish Literature*, to the close of the sixteenth century. Besides those mentioned, there are Ruda; Olof Fryxell, brother of the historian; Hedborn; Adlersparre; Braun; Lindeblad; Ridderstad; Satherberg; Blanché, a vaudeville writer; Strandberg, the poet of freedom; Malmström; Nybom; and Bergman; Gosselman, a naval officer and traveller; Unge, also officer and traveller, a humorous poet; Sturzenbecher, a brilliant writer of the Heiné school; Carlén, the husband of the novelist; Nervander, translator of poetry of King Ludvig of Bavaria; Wennström, Goransson, and numbers of rising men; Hagbart, the excellent translator of Shakspeare, in twelve volumes, which he has presented to the Shakspeare Society in England.

THE ROMANCE AND NOVEL WRITERS OF SWEDEN.

Whilst the literature of Sweden is almost wholly modern, its romance and novel literature is especially so. Mörk, about the middle of the eighteenth century, was the first to cultivate prose fiction. His models were Fenelon, Lowenstein, and Barclay; his productions were heavy, bombastic, diffuse, and monotonous. Their titles indicate their character, as *The Romance of Adalrik and Göthilda*,

Scandinavian literature.

Scapula.

Eugenia, or the Bewildered Well-meaning One. He died in 1763. From that period to the end of the century the country was inundated with foreign romances. La Fontaine's *Wood Child, Subterranean Burial Vault, &c.*, cost more tears and candle-ends than can be well counted. But all this unsound stuff had its day. Hobgoblins, like other horrors, vanished; interesting robbers ceased to show themselves after Rinaldo; even Kotzebue's monstrosities grew insipid. Palmblad and Cederborg then introduced something more real and amusing. Cederborg became the most popular. His *Uno von Träsenberg* and *Otto Tralling* were much of the *Tom Jones* school; but his novels, which passed rapidly through numerous editions, abounded with real Swedish life and characters, and are read by many with pleasure. He was the Dickens of Sweden of his day. In 1843 he published a new edition of his works. Walberg was a disciple of Cederborg, in *Uggelvik's Ball*, and the writers of *Fuselbrenner, Baron Dolk, &c.* Two lady novelists also appeared, Fröken R*** and Fröken Cronhjelm, but of no great note. G. W. Gumælius, who wrote *Thord Bonde*, in imitation of Walter Scott, was the first historic romance writer. Clas Livijn, the poet, Count Peter Sparre, "O. K.," author of *Snapphanarne, &c.*, and Mellin, are all novelists of note. Mellin has also written a *History of Sweden for Ladies*. We have already spoken of Almquist's romances; and we may mention the names of Mamsell Stahlberg and Mina Gronwall, as well as Kullberg, author of *Gustavus III. and his Court*.

But now appeared Sweden's great novelist, Miss Bremer, whose works are so well known to England, through Mrs Howitt's translations, that we need only mention them. Besides her novels, Fredrika Bremer has published her *Homes in the New World*. Her success called forth two other ladies in the same department of literature who have become famous,—the Baroness Knorring and Emily Carlén. The Baroness Knorring, now deceased, is the George Sand of Sweden, exhibiting much of his genius and of his peculiar notions. One of her stories, *Torparen, or the Peasant and his Landlord*, is a masterly production. Emily Carlén is perhaps a more prolific writer than Miss Bremer, and enjoys great popularity in Sweden; it has been said a greater popularity than Miss Bremer. This is not the case. Professor Lenstrom, the historian of Swedish literature, pronounces his verdict in a few decisive words:—"Fredrika Bremer is Sweden's greatest female writer of romance;" and Dr Sturzenbecher says, "she has carried our native literature farther than any of our literary notabilities before."

Besides these, Sweden possesses other distinguished living writers of fiction. Wetterbergh, who writes under the name of Uncle Adam; Engström, who exposes the vast inequalities of society; Snellman, a Finn; De Geer, a mem-

ber of a noble family and a government official, who writes under the initials "S. H. T.;" Odman, a professor of Upsala; and Crusenstolpe and Lindeberg, two of Copenhagen's most brilliant journalists, who are equally celebrated in fiction.

Scarborough.

Here we close our sketch of the literature of Scandinavia. It is but a sketch—a mere outline—of the mass of literary, poetical, and imaginative wealth spread over the northern lands of our stalwart forefathers; and it would be unjust not to add that in all other branches of letters, in science, in art, the drama, in jurisprudence, in philosophy, Scandinavia stands on a fair eminence, and promises in a few years to assume a position challenging comparison with any country of Europe. Let the reader turn over the *Swedish Biographical Lexicon*, or Lenstrom's *Synopsis of the Literature and Art of Sweden*, his *Poesiens Historie*, the *Nordisk Conversations Lexicon*, now publishing in Copenhagen, and similar works, and see what hosts of able authors in every species of intellectual activity present themselves; that whole libraries have been accumulated under their hands, in all sciences,—history, philology, theology, antiquities, every branch of natural and moral philosophy, and every kind of miscellaneous literature. Look back through the past, what world-wide names! Puffendorf, the author of *Jus Naturæ et Gentium*, and other works, philosophic and historic. Linnæus, Swedenborg, who would have taken one of the highest places as a discoverer in science had he not stood forward as a great theologic seer. The names of Scheele and Berzelius are familiar to all chemical students. In history, Sweden presents great names, from Saxo Grammaticus to Geijer, Fryxell, and Strinholm, author of the *History of the Vikings*. In literary history, Hammar-kold, Wieselgren, and Lenstrom. In contemporary art, Bystrom, Gothe, and Fogelberg, as sculptors, are eminent names; in painting of different kinds, Sodermark in portrait, Sandberg in portrait and historic painting, Mörner, historic painter, Dahlgren, and others. Fröken Rothkirch is distinguished in portrait, and Fahlcranz in landscape painting from northern scenery, in which department ladies have also distinguished themselves, as Evelina Stading and Mamsell Linnell. Besides these, Julin, Ezdorff, Hédec-ken, Soderberg, the Anckarswårds, one an animal painter; Kylberg, a painter of humorous subjects; Lauræus, a Finnish *genre*-painter; and many others, deserve particular notice. The great names in all these departments of art and science belonging to Norway and Denmark we have already mentioned. The more we study the literature of these nations, the more we shall perceive traces of our real ancestry, and that we have yet kindred in the North who are essentially worthy of being known where Canute the Great once reigned.

(W. II.—T.)

SCAPULA, JOHN, was born probably at Lausanne towards the end of the sixteenth century, and studied at Lausanne. His name is recorded in the annals of literature, neither on account of his talents, nor learning, nor virtuous industry, but for a gross act of disingenuity and fraud which he committed against an eminent literary character of the sixteenth century. Being employed by Henry Stephens as a corrector of his press while he was publishing his *Thesaurus Linguae Græcæ* in 1572, Scapula extracted those words and explanations which he reckoned most useful, comprised them in one volume, and published them as an original work, with his own name. This book appeared in 1579, and bore the title of *Lexicon Græco Latinum*. The compilation and printing of the *Thesaurus* had cost Stephens immense labour and expense; but it was so much admired by those learned men to whom he had shown it, and seemed to be of such essential importance to the acquisition of the

Greek language, that he reasonably hoped his labour would be crowned with honour, and that the money he had expended would be repaid by a rapid and extensive sale. But before his work came abroad, Scapula's abridgment appeared, which, from its size and price, was quickly purchased, while the *Thesaurus* itself lay neglected in the author's hands. The consequence was a bankruptcy on the part of Stephens, while he who had occasioned it was enjoying the fruits of his treachery. Scapula's *Lexicon* was afterwards enlarged, and published in folio; and has gone through several editions, while the valuable work of Stephens has never been reprinted. Its success is, however, not owing to its superior merit, but to its moderate price and commodious size.

SCARBOROUGH, a seaport and market-town, municipal and parliamentary borough of England, in the North Riding of Yorkshire, 39 miles N.E. of York, and 217 N. of London. It occupies a fine situation, on the shore of the

Scar-
borough.

German Ocean, along a semicircular bay, protected on the N. and N.E. by steep heights, crowned by the old castle. Originally built close to the sands, it now extends for some distance up the slope behind, the houses rising in successive tiers one above another. The upper and more modern part of the town is very handsome, consisting of broad, well-paved streets, lined with elegant houses. There are many public buildings, some of which are remarkable for beauty. Among them are a town-hall, jail, and custom-house. Very conspicuous is a fine circular edifice, in the classical style, recently built for the accommodation of a museum, which forms a valuable collection, illustrative of the geology and natural history of the county. The ancient but now dilapidated castle stands on a cliff from 300 to 330 feet high, and is still used for barracks; and protects the town and harbour by means of three batteries. It formerly covered 19 acres, and was accessible only from the west. The massive square keep, and parts of the gate barbacan, and ditch, are still to be seen. The old church of St Mary occupies the site of a former Cistercian priory, of which some portions of the crypt and one of the ancient towers still remain. Christ Church is a fine Gothic edifice, erected in 1828. The Established Church have also a chapel of ease; and there are other places of worship belonging to various sects, of Methodists, Baptists, Independents, Quakers, Christian Brethren, and Roman Catholics. Education is well provided for by a grammar school, with thirty scholars in 1854, a Lancasterian school, national schools, and others of various kinds. There are also two public libraries, and a mechanics' institution; besides the museum already mentioned. The charitable institutions comprise—alms-houses, a poor-house, and a seamen's hospital. Scarborough owes its prosperity chiefly to its mineral wells and to its advantages for sea-bathing, which render it a favourite place of resort for summer visitors. There are two mineral springs, the north and the south, differing somewhat in their chemical ingredients. They have long been in high repute as beneficial to invalids. A large castellated saloon has been erected at the place where these springs rise, at the foot of the cliff near the sea. This place is separated from the town by a ravine 400 feet wide, which is spanned by a handsome iron bridge of 4 arches, supported on piers 75 feet high. The amusement and recreation of the visitors are provided for by a theatre, assembly-rooms, news-rooms, and public gardens. Ship-building is largely carried on at Scarborough, as well as the manufacture of ropes and sail-cloth; but these branches of industry have in recent times considerably declined. The herring fishery, during its season, employs many boats belonging to the town, and there are several coal mines in the neighbouring country. The harbour is of some importance, as it is the only good one between Whitby and the mouth of the Humber. It has two piers; and though the entrance is narrow, it is commodious and safe. Scarborough was made a bonding port in 1841: it has bonding warehouses and a lighthouse. Some foreign trade is carried on, chiefly with the Baltic, Holland, and Portugal; iron, timber, hemp, flax, wine, and brandy, being the chief articles imported. There is also some coasting trade. The number of sailing vessels registered at the port, December 31, 1857, was 299; tonnage, 36,470: of steam vessels, 3; tonnage, 452. In that year the number of vessels that entered the port, all sailing vessels, was 330; tonnage, 20,788: those that cleared, also all sailing vessels, were 46; tonnage, 2271. Scarborough is governed by a mayor, 6 aldermen, and 12 councillors; and returns 2 members to parliament. The town is believed to be ancient, on account of its name, which is Saxon, signifying *the fortified rock*; and it was at one time strongly defended by walls, moat, and earthen ramparts. The castle must have been a place of great strength before the use of gunpowder; and even during the civil war it held out for a long time

against the parliamentary forces. It was dismantled under the Commonwealth, but partially repaired again at the time of the rebellion in 1745. Pop. (1851) 12,915.

Scarlatti.

SCARLATTI, ALESSANDRO, one of the greatest modern musicians, was born at Trapani, in Sicily, in 1659, and died at Naples, on 24th October 1725, aged sixty-six years, as is shown by the inscription on his tomb in the church of the Carmelites of Monte-Santo. Who were his early instructors in music is not known. It seems hardly possible that he should have studied under Carissimi, at Rome, as has been so often said; because when Scarlatti was fifteen years old, Carissimi was ninety-four. Scarlatti visited Rome in 1680, but it is not probable that Carissimi was then living. In that year, his first opera, *L'Onestà Nell' Amore*, was performed at the court of Christina of Sweden. It has been said that another opera of his was performed in the same year at the court of Munich; but it appears that no opera of Scarlatti's was performed there before 1721. His opera, *Pompeo*, was performed at the court of Naples on 30th January 1684. After that we learn nothing of his proceedings until 1693, when he composed the oratorio, *I Re di Maria sempre Vergine*, and the opera, *Theodora*, performed at Rome. In this opera he gave the first example of a *da capo*; a form adopted by other composers, and employed for many years afterwards. He introduced another novelty, *i.e.*, orchestral accompaniments to the recitatives; and he also gave a separate design to the accompaniments of the airs. It appears that, in 1694, he held the office of chapel master-royal at Naples. His opera, *Pirro e Demetrio*, performed at Naples in 1697; *Il prigionier fortunato*, in 1698; and especially *Laodicea e Berenice*, 1701, established his reputation. On 31st December 1703, Scarlatti was called to assist Foggia, chapel-master of Santa Maria Maggiore, at Rome; and in May 1707 succeeded that eminent musician. He held also the office of music-director to Cardinal Ottoboni, who seems to have obtained for him the decoration of Knight of the Golden Spur. At that time the new political condition of Naples induced Scarlatti to return thither in 1709, after resigning his appointments in Rome. Among the operas which he produced at Naples was *Il Tigrane*, performed in 1715; and in a note subjoined to the argument of the drama, Scarlatti states that he had then composed 106 operas for different Italian theatres. He afterwards composed eleven others, besides several oratorios, and a great deal of church music. In *Tigrane* he formed new orchestral instrumentations, unknown till then. Scarlatti composed a vast number of cantatas, most of which remain in manuscript. He taught by turns in the conservatories of Sant' Onofrio, Dei Poveri di Gesù Cristo, and Santa Maria di Loreto. The famous Duante was one of his pupils, and arranged several of Scarlatti's cantatas as duets in a most masterly manner. Mirecki published these arrangements, along with Clari's duets and trios, at Paris. Scarlatti's genius and fertility were extraordinary. His invention was rich and bold, his learning great, and his style pure. His modulations, often unexpected, are never harsh, and never difficult for the voice. Besides the music above-mentioned, Scarlatti composed the following pieces for the chamber. Twenty madrigals; a serenata for four voices; two serenades for five voices; madrigals for two voices; fourteen chamber duets, for study; two books of toccate, for the harpsichord or organ. A specimen of Scarlatti's vocal music is given by Burney, in the fourth volume of his *History of Music*; and another by Padre Martini, in the second volume of his work on counterpoint. Clementi, in his *Selection of Practical Harmony*, 3 volumes, gives specimens of instrumental music by Alessandro and Domenico Scarlatti. (G. F. G.)

SCARLATTI, Domenico, son of Alessandro Scarlatti, was a very distinguished composer, and one of the ablest harpsichord players in Europe. He was born at Naples in 1685

Scarlet
Fever.

and studied at first under his father, and afterwards under Gasparini, at Rome. In 1709, he met with Handel, at Venice, and was delighted with the surprising improvisations of that great master. At Rome, he composed a great number of excellent cantatas, and wrote also for the church. On 1st January 1715, he was appointed chapel-master of St Peter's, in the Vatican, but quitted that post in August 1719, when he went to London, in order to compose an opera, and to accompany on the harpsichord at the Italian Opera. He there produced *Narcisso* on the 30th May 1720; and next year set out for Lisbon. The king of Portugal engaged him, and treated him very liberally. In 1726, he returned to Naples, but finding his great instrumental talent of small advantage to him in Italy, he accepted, in 1729, an offer from the court of Spain to give lessons to the Princess of the Asturias, whom he had formerly taught at Lisbon, as Princess of Portugal. At Madrid he enjoyed great advantages, which were continued to him by Ferdinand VI., in whose service he remained till his death in 1757. He published two sets of sonatas for the harpsichord, dedicated to the Princess of the Asturias, besides other sonatas. His sonatas are remarkable for invention, for graceful melody, and skilful construction. The number of his sonatas is wonderful. The Abate Santini, at Rome, had collected 349 of Domenico Scarlatti's sonatas for harpsichord and organ, and yet had not obtained all that he had written. Clementi, in the second volume of his *Selections*, gives two fugue specimens of Domenico Scarlatti's music, one of them the celebrated Cat's Fugue. (G. R. G.)

SCARLET FEVER (*Scarlatina*), either mild, or malignant with putrid sore throat, exhibits different forms of a disease which is propagated by a specific contagion, like small-pox or measles, and like them is believed by the best observers to attack a person only once during life; though the apparent exceptions to this remark are more numerous in scarlet fever than in the other two diseases above mentioned. It will be proper to notice separately, the mild and fatal scarlet fever; and to describe some cases, in which the symptoms are irregularly combined.

The *milder form* of scarlet fever is distinguished by the rash, with a moderate degree of fever, and with very little affection of the throat. The rash first appears in innumerable red points about the neck and face, and by the next day they are seen over the whole surface of the body. The skin is rough to the touch, and sometimes there are small vesicles. About the fourth day, the eruption is at its height, and on the fifth it begins to decline. The patient should be kept cool and quiet, should not be overloaded with bed-clothes; his diet should be sparing, and cooling drinks and mild laxatives should be recommended.

In the *severer forms* of *Scarlatina* the febrile symptoms at the commencement are more severe; there is a sensation of stiffness and pain on moving the neck, and it is also painful to swallow; the voice is thick, and the throat feels rough and straitened. The heat of the surface rises in a most remarkable manner; not only to the sensations of the patient or observer does the heat seem greater, but the thermometer shows it to be 108° to 110° ; that is more than ten degrees above the natural standard. There is sickness, headache, great restlessness, and delirium; the pulse is frequent, but feeble, and there is great languor and faintness. The tongue is of a bright red colour, especially at the sides and extremity, and the rising points are very conspicuous. This kind of scarlet fever is not unfrequently followed by great debility, or the occurrence of other diseases, as inflammation of the eyes, or dropsy, or an inflammatory state of the whole system, or water in the brain.

Treatment. It is in general proper to begin with giving an emetic, especially if we at all suspect the stomach to be loaded with undigested matter; and we are very soon after to exhibit laxative medicines, which are truly one of our

most important remedies in this disease. The washing of the patient's body with cold water, is considered a good antidote to lessen the burning heat of the skin. The inflammatory state of the system which often follows scarlet fever, is not unfrequently accompanied with a swelling resembling dropsical swelling; but we are not to regard this last as a sign of debility, or to be deterred from the use of active remedies.

In *Malignant Scarlet Fever*, with putrid sore throat, the putrescent symptoms are more rapid and severe, and the general system is much oppressed, the throat and neighbouring parts being affected with rapidly spreading ulcerations. This form of scarlet fever begins with a cold, preceding, but in a day or two shows symptoms of peculiar severity. The rash is usually faint, and the whole skin soon assumes a dark or livid red colour.

Treatment. Strong beef-tea should be given in as large quantities as possible, and wine and bark should be liberally administered; the throat must be injected with strong cleaning gargles.

SCARPA, ANTONIO, was born at La Motta, in 1748. He early distinguished himself as an anatomist and surgeon, and his works in both these branches of science have spread his reputation throughout all Europe. For many years he occupied the chair of clinical and operative surgery in the school of Pavia; and when he became emeritus professor, he was really the director of the faculty of medicine in the university which he so greatly contributed to render celebrated. Scarpa was an exact as well as a laborious observer, and did more than most men of his time to advance the progress of surgery. Surgical anatomy, which has given a particular direction to the researches of surgeons, owes its first development to the labours of Scarpa, and forms, in some sort, the distinctive character of his productions. His works are not altogether free from faults. They recommend themselves more by the beauty than by the precision of their style; but the excellence of the precepts which his writings convey, and the judicious and original observations on which they are based, have placed several of them in the rank of classical books, and have led to their translation into most of the languages of Europe. Scarpa commenced his career as an anatomist, but afterwards directed his attention principally to the practice of surgery; and if he sometimes maintains opinions that are paradoxical, if his theories and his precepts are at times hardly defensible, we still recognise, even in his errors, the views of a great master, and thoughts which direct the reader to useful reflection. Uniting to the love of science an exquisite taste for the fine arts, the author has illustrated his writings with engravings, which are models of exactness, elegance, and purity. The plates which represent the nerves of the heart, and those which accompany the treatises on hernia and aneurism, are among the most perfect productions of this kind. He died at Pavia, on the 30th of October 1832.

Scarpa is author of a number of writings, many of them inserted in the journals of Italy, and on local subjects which are little known. His principal works are, *Anatomicae Disquisitiones de Auditu et Olfactu*, Pavia, 1789, in folio; *Tabulae Neurologicae ad Illustrandum Historiam Cordiacorum Nervorum*, Pavia, 1794, in folio; *Commentarius de Penetratione Nervorum in Structura Testis*, 1799, in 4to; *Sull' Ernie*, *Memorie della Società di Scienze e Lettere*, 1810, in folio; *Illustrazioni ed Osservazioni Anatomico-chirurgiche sull' Aneurisma*, Pavia, 1804, in folio; *Saggio di Osservazioni ed Esperienze sulle principali Malattie degli occhi*, Pavia, 1801, in 4to; *Sul taglio Ipogastrico per l'Estrazione della pietra dalla Vesica Orinaria*, Milan, 1820, in 4to; *Sullo Scirro e sul Cancro*, Milan, 1821, in 4to; *Memoria sulla Ligatura delle principali Arterie*; *Lettera sulla Ligatura temporaria delle grosse Arterie degli arti*, Milan, 1823, in 8vo; *Saggio di Osservazioni sul taglio Retto-vesicale per l'Estrazione della pietra dalla Vesica Orinaria*, Pavia, 1823, in 8vo; *Esame della terza Memoria del Professore Vacca sul taglio Retto-vesicale*, Milan, 1824, in 8vo; *Memoria sull' Idrocele del Cordone Spermatico*, Pavia, 1823, in 4to.

Scarpa.

Scarpanto
Scarron.

SCARPANTO, an island of Asiatic Turkey, lying in the Mediterranean, 28 miles S.W. of Rhodes. It is about 30 miles long by 5 across; and is very lofty, rugged, and bare, having one summit near the centre. 4000 feet above the sea. Marble and iron are its chief productions; and there are some harbours on its coasts. The ancient name was Carpathus.

SCARRON, PAUL, a famous French burlesque writer, was the son of a counsellor in parliament, and born at Paris about the end of the year 1610, or in the beginning of the succeeding year. His father having married a second time, he was compelled to assume the ecclesiastical profession. At the age of twenty-four he visit Italy, where he freely indulged in licentious pleasures. After his return to Paris, he persisted in a life of dissipation, till a long and painful disease convinced him that his constitution was almost worn out. At length, when engaged in a party of pleasure, at the age of twenty-seven, he lost "the use of those legs which danced so gracefully, and of those hands which could paint and play on the lute with so much elegance." In the year 1638 he was attending the carnival at Mans, of which he was a canon. Having dressed himself one day as a savage, his singular appearance excited the curiosity of the children of the town. They followed him in multitudes, and he was obliged to take shelter in a marsh. This wet and cold situation produced a numbness which totally deprived him of the use of his limbs; but notwithstanding this misfortune he continued gay and cheerful. He took up his residence at Paris, and by his pleasant humour soon attracted to his house all the men of wit about the city. The loss of his health was followed by the loss of his fortune. On the death of his father, he entered into a process with his mother-in-law. He pleaded the cause in a ludicrous manner, though his whole fortune depended on the decision, and accordingly lost the cause. Mademoiselle de Hautefort, compassionating his misfortunes, procured for him an audience of the queen. The poet requested to have the title of valetudinarian to her majesty. The queen smiled, and Scarron considered the smile as the commission to his new office. He therefore assumed the title of "Scarron, by the grace of God, unworthy valetudinarian to the queen."

Cardinal Mazarin gave him a pension of 500 crowns; but that minister having received disdainfully the dedication of his *Typhon*, the poet immediately wrote a *Mazarinade*, and the pension was withdrawn. He then attached himself to the Prince of Conde, and celebrated his victories. He at length formed the extraordinary resolution of marrying, and was accordingly, in 1651, married to Mademoiselle d'Aubigné, afterwards Madame de Maintenon, who was then only sixteen years of age. "At that time," says Voltaire, "it was considered as a great acquisition for her to gain for a husband a man who was disfigured by nature, impotent, and very little enriched by fortune." When Scarron was questioned about the contract of marriage, he said he acknowledged to the bride two large invincible eyes, a very beautiful shape, two fine hands, and a large portion of wit. The notary demanded what dowry he would give her. Scarron immediately replied, "The names of the wives of kings die with them, but the name of Scarron's wife shall live for ever." She restrained by her modesty his indecent buffooneries, and the good company which had formerly resorted to his house were not less frequent in their visits. Scarron now became a new man. He grew more decent in his manners and conversation; and his gaiety, when tempered with moderation, was still more agreeable. But, in the meantime, he lived with so little economy, that his income was soon reduced to a small annuity and his marquise of Quinet. By the marquise of Quinet, he meant the revenue he derived from his publications, which were printed by one Quinet. He was

VOL. XIX.

Scarron.

accustomed to talk to his superiors with great freedom, in his jocular style. In the dedication to his *Don Japhet d'Armenie*, he thus addresses the king: "I shall endeavour to persuade your majesty that you would do yourself no injury were you to do me a small favour; for in that case I should become more gay. If I should become more gay, I should write sprightly comedies; and if I should write sprightly comedies, your majesty would be amused, and thus your money would not be lost. All this appears so evident, that I should certainly be convinced of it if I were as great a king as I am now a poor unfortunate man."

Although Scarron wrote comedies, he had neither time nor patience to study the rules and models of dramatic poetry. Aristotle and Horace, Plautus and Terence, would have frightened him; and perhaps he did not know that there was ever such a person as Aristophanes. He saw an open path before him, and he followed it. It was the fashion of the times to pillage the Spanish writers. Scarron was acquainted with that language, and he found it easier to use the materials which were already prepared, than to rack his brains in inventing a subject; a restraint to which a genius like his could not easily submit. As he borrowed liberally from the Spanish writers, a dramatic piece did not cost him much labour. His labour consisted not in making his comic characters talk humorously, but in keeping up serious characters; for the serious was a foreign language to him. The great success of his *Jodelet Maitre* was a vast allurements to him. The comedians who acted it eagerly requested more of his productions. They were written without much toil, and they procured him large sums. They served to amuse him. When the office of historiographer became vacant, he solicited for it without success. At length Fouquet gave him a pension of 1600 livres. Christina, Queen of Sweden, having come to Paris, was anxious to see Scarron. "I permit you," said she to Scarron, "to fall in love with me. The Queen of France has made you her valetudinarian, and I create you my Roland." But Scarron did not long enjoy that title. He was seized with so violent a hiccup, that every person thought he would have expired. "If I recover," he said, "I will make a fine satire on the hiccup." His gaiety did not forsake him to the last. Within a few minutes of his death, when his domestics were shedding tears about him, "My good friends," said he, "I shall never make you weep so much for me as I have made you laugh." Just before expiring he said, "I could never believe before that it is so easy to laugh at death. He died on the 14th of October 1660, in the fifty-first year of his age.

His works have been collected and published by Bruzen de la Martiniere, in 10 vols. 12mo, 1737. There are *The Æneid travestied*, in eight books. It was afterwards continued by Moreau de Brasey; *Typhon, or the Gigantomachia*. Many comedies, as *Jodelet, or the Master Valet*, *Jodelet Cuffed*, *Don Japhet d'Armenie*, the *Ridiculous Heir*, *Every Man his own Guardian*, the *Foolish Marquis*, the *Scholar of Salamanca*, the *False Appearance*, and the *Prince Corsaire*, a tragi-comedy. Besides these, he wrote other pieces in verse. His *Comic Romance*, in prose, is the only one of his works that deserves attention. It is written with much purity and gaiety, and has contributed not a little to the improvement of the French language. It has been translated into English by Oliver Goldsmith. Scarron had great pleasure in reading his works to his friends as he composed them, which he called "trying his works." Segrais and another of his friends coming to him one day, "Take a chair," said Scarron to them, "and sit down, that I may examine my *Comic Romance*." When he observed the company laugh, "Very well," said he, "my book will be well received, since it makes persons of such delicate taste laugh." Nor was he deceived. His romance had a prodigious run. It was the only one of his works that Boileau could submit to read. *Spanish novels* translated into French. A volume of *Letters*. *Poems*, consisting of songs, epistles, stanzas, odes, and epigrams. The whole collection abounds with sprightliness and gaiety, and his works have nearly all been translated into English.

SCEPTICISM.

Scepticism described. SCEPTICISM (*σκέψις*, *doubt*), is that negative species of philosophy which, founding on the alleged contradiction, whether direct or indirect, of the primary data of consciousness, pronounces philosophy false and truth impossible; or, more briefly, it is that negative system of philosophy which, by doubting of everything beyond the region of phenomena, doubts the possibility of all speculation.

The relation of Scepticism to Dogmatism.

In order to doubt, man must begin somewhere, and the admission by the sceptic of the truthfulness of phenomena is alike necessary and convenient. For an absolute scepticism regarding the energies of the human faculties, even when admitted to be self-consistent, and acquitted of contradiction, is, as self-destructive, absolutely impossible.¹ If I am sceptical of my own faculties when they doubt, this very scepticism annihilates that doubt, and renders me incapable of advancing a step. The highest form which scepticism can assume is that of convicting the data of consciousness of mutual exclusiveness, whether possible or actual.² It is the business of the sceptic, accordingly, to destroy, not to establish; to pull down, not to build up. He accepts his premises from the dogmatist, and strives, by bringing them into hostile collision, to convict him of absurdity. It is the business of the dogmatist to develop with consistency the facts which consciousness reveals; it is the business of the sceptic to review the labours of the dogmatist, and discover, if possible, an inconsistency in the primary facts which are subjected to his criticism. The function of the sceptic is quite a legitimate one, accepting as he does both his method and his material from the dogmatist; but pursuing his aim in an entirely different spirit, and with a widely different end. The highest end of the dogmatist is to produce an intellectual harmony; the highest end of the sceptic is to generate an intellectual chaos. The intuition of truth is what the dogmatist seeks; what the sceptic longs for is the absolute doubtfulness of all conviction. Both start from common ground in starting from the acceptance of phenomena; both arrive at directly opposite conclusions in arriving, the one at affirmation, the other at doubt.³ The dogmatist, the emblem of impatience, is earnest and incessant in his pursuit of truth; the sceptic, the picture of composure, is finely indifferent and delightfully dubious over everything which claims the name of truth. The dogmatist, positive in his assurance of the criterion of what he seeks, has a constant trust in the attainability of philosophy; the sceptic, on the other hand, who harbours the sole conviction that all truth is vain, believes (if a sceptic can be said to believe) in the absolute impossibility of philosophy. Dogmatist and sceptic alike agree in accepting the foundations of knowledge; the dogmatist, reliant on the strength of his intuitions, boldly pushes beyond phenomena, and affirms his conviction of the existence of self, the world, and Deity as entities; the sceptic, again, who freely doubts all intuitions, chooses to think of these essences as so many popular illusions, or at best as so many fond dubieties. The dogmatist accepts of his intuitions, and carelessly multiplies or as carelessly diminishes them; the sceptic, ever on the watch, argues their original falsehood from their positive contradiction in the hands of the dogmatist. The veracity of consciousness, so far as testifying to the truthfulness of phenomena are, at the outset,

accepted alike by dogmatist and sceptic; and it depends entirely on the measure of consistency with which the dogmatist shall work out his problem, whether or not he shall have left room for the keen-eyed and persistent sceptic. If the dogmatist succeeds in elaborating his undertaking throughout with entire consistency, philosophy and nature will be reconciled; but if he does not succeed in this endeavour, consciousness will prove only a bundle of antilogies, and scepticism will reign supreme. Considered under one aspect, the sceptic stands opposed to the dogmatist and not to truth, in so far as he engages to convict of contradiction the principles which philosophy has developed. Considered under another and a higher aspect, he stands opposed both to truth and dogmatism, in so far as he doubts of everything beyond phenomena, in convicting of contradiction the principles on which philosophy itself is founded. The former may be called *relative*, the latter *absolute* scepticism.⁴ It will thus be seen what are the legitimate relations of sceptic and dogmatist. That man is not a sceptic who exercises doubt as a means, but not as an end. This temporary doubt is but a passing phase of every strong and earnest mind in search of the truth. In the intellectual constitution of some, and particularly of those in whom their intuitions prove too strong for their logic, this salutary disposition becomes temporarily tainted as by a sort of predominating disease. Yet it is the truth which the thinker is in search of, and not universal doubt as an ultimate end. Not a few of the most illustrious thinkers which the world has known seem to have spent much of their time in this atmosphere. Witness the *Analogy* of Bishop Butler and the *Pensées* of Blaise Pascal, where abundant evidence will be found, particularly in the under-current of those writers' minds, of the truthfulness of this statement. What is usually known as the Cartesian doubt is by no means an uncommon feature in the history of thoughtful men. "Who never doubted, never half believed."

Speculative thought had scarcely dawned upon the minds of the Grecian sages, when scepticism began stealthily to calumniate its doubts. No sooner had dogmatism fairly gained time to develop itself into full blossom, than we find scepticism, its negative correlative, springing up in its shade. As action and re-action constantly recur with the force of their compensating influence, so the speculative efforts of Socrates, of Plato, and of Aristotle, required to be succeeded by the destructive philosophy of Pyrrho of Elis and his school. Plato had developed his ideal theory to find it rudely taken to pieces by Aristotle, who afforded to philosophy as baseless a foundation, in his boasted *Logic*, as the system of speculation which he had so ruthlessly destroyed. If Plato's theory could be shown to be misleading, a similar proof could be led against that of his opponent. Sense could only furnish the mind with outward phenomena, and formal logic could carry it no farther. It is the privilege of logic to analyse and regulate, not to synthesize and amplify. It belongs not to logic, but to a quite different department of human knowledge, to furnish the material out of which to construct a philosophy of real convictions. As at once the law of thought and of things, logic is properly both subjective and objective. It is constantly engaged on the evolution of identical propositions,

¹ Yet this self-contradictory principle is that which Jouffroy, usually so just a thinker, calls the "one irrefutable argument of scepticism." (See *Mélanges Philosophiques*.)

Scepticism and at no point in any process of demonstration is it possible to detect any addition made to the quantum of existence already realized. To metaphysics it belongs to furnish the facts of existence which are competent to human knowledge. Thinking, under this relative phase, neither Plato nor Aristotle had taken any definite account of; and hence Pyrrho and the sceptics seized upon this, the vulnerable portion of their systems. If one were to trust the absurd stories related of the practical life of Pyrrho,¹ one would be necessitated to suppose him to have been little less than crazy. Such, however, we may be assured he was not. He seems to have been strongly impressed with the mystery and consequent incomprehensibility (*ἀκαταλήψια*) that surrounded the little life of man. He studied in his early years the doctrines of Democritus, and in his maturer life he followed Alexander into India, bent on philosophical conquest, as his master was upon territorial aggrandizement. He studied the doctrines of the Magi, and held converse with the Gymnosophists. Struck by the devout faith of the latter in doctrines so singular and so unusual to the mind of a Greek, he doubtless reflected deeply on the origin of knowledge, and particularly on the formation of belief. On his return to Elis, men found that he had lost all faith in philosophy: he viewed all doctrines with a profound scepticism, and began to live a life of wonderful simplicity and of wonderful indifference. He died at the age of ninety, and bequeathed his name to all succeeding sages who might choose to adopt his system of opinions.² The next thinker of any note who chose Pyrrhonism or Scepticism as his creed was Timon, a physician of Phlius (B.C. 279), a keen and restless wit, and a man of genius, who wrote those satirical poems known as *Σάλλοι*. If further proof were wanting of the perfect sanity of Pyrrho, the faithful adherence of this caustic humorist, who was wont to wonder how his master could contrive to live "the only man as happy as a god," were sufficient of itself to establish it. Timon was much too great a humorist to follow Pyrrho if he had not been really worthy of being followed. After the Pyrrhonian Numenius, Cyprus and Seleucia afforded two pupils to Timon, in Diocorides and Euphranor, who served to close the old sceptical school of Greece. Its adherents taught the complete renunciation of all science, and the necessity of maintaining a complete apathy to all impressions.³

The Pyrrhonics gathered fresh strength in the new sceptical school, which was inaugurated by one of its most distinguished advocates, Ænesidemus, who flourished a little later than Cicero. To this philosopher is generally ascribed the systematizing or invention of the ten topics employed by Sextus Empiricus to justify a suspense of all positive opinion. The criticism offered by Ænesidemus of the principle of Causality is certainly the boldest and most ingenious to be found in the records of the ancient philosophy. The force of his argument lay in the alleged incapability of the human mind to understand the relations of cause and effect. Of his eight books of Pyrrhonian discourses (*Πυρρῶναιων λόγων ὅκτα βιβλία*) only a few fragments now remain. Herodotus of Tarsus, Menodotus, Agrippa (said to be the author of the "five grounds of doubt" current among the later sceptical thinkers), and Antiochus of Laodicea, kept up the sinking credit of the Pyrrhonists till the appearance of Sextus Empiricus (about A.D. 290), a distinguished pupil of Herodotus of Tarsus, and an acute and thoughtful writer. In his Pyrrhonian Outlines, and his books against the Mathematicians (or dogmatists), he has left us an invaluable

Sextus Empiricus.

repository of information respecting the schools of ancient Scepticism.⁴ This writer was a native of Mitylene, and received his surname, *Empiricus*, from his connection with that empirical school of physicians who, discarding all science, based their knowledge entirely upon experience. While he availed himself of the labours of his predecessors, and especially of Ænesidemus, of Agrippa, and of Menodotus, it is evident from what he has left, that he was capable of higher efforts, both in defining the end and working out the details of a rigorous system of doubt. In his three books, *Πυρρῶναιων Ὑποτυπώσεων*, he discusses in a fair and unusually candid manner the radical distinction between the sceptics and the dogmatists, and works out with much acuteness and spirit the various contradictions, as they presented themselves to his mind, of the problems of Sense and of Logic, with an occasional detour into the region of Metaphysics. If he ever indulges in humour, it is usually of a mild and impersonal character, and never displays anything of that wild satirical banter with which Timon delighted to cover his opponents. The first book of the Pyrrhonian Outlines is occupied with a general exposition of scepticism; in the two remaining books the author takes the dogmatists to task respecting the various problems which occupy their philosophy. He opens his first book by a chapter devoted to Dogmatics and Sceptics, in which he shows that they form the two great classes of philosophical thinkers. Towards the end of that chapter he throws in a sceptical caution in these words: "I wish to advertise my readers as to what I shall advance, that I do not pretend to establish things as they are, and that I cannot at all assure them that things are as I speak of them." Having thus made his bow to his audience, he proceeds to lay before them a definition of scepticism. "The sceptical faculty is," according to Sextus, "that by which we oppose phenomena and noumena in all possible ways, and by which we arrive, through a counterpoise of things and arguments, first at a suspension of judgment (*ἐποχή*), and afterwards at entire freedom from passion (*ἀπαρξία*)."⁵ The aim which the sceptic proposed to himself was accordingly twofold: first, intellectual, to reach absolute suspension of judgment; and second, moral, to attain to a condition of perfect calm. The latter alternative was probably supposed to depend entirely on the accomplishment of the former; so that when the doubter had reached the absolute state of intellectual suspense, he would necessarily experience in his inmost soul that perfect quiet which the thinker so greatly longs for. At all events, little attention was given by the ancient Pyrrhonists to this the moral part of their task. We shall confine attention exclusively to the intellectual phases of scepticism, and give a running outline of these celebrated *Hypotyposes*. They are a summing up of all previous Pyrrhonic ideas, and succeeding sceptics, Hume included, have only, with a slight divergence, traversed the old road.

It will be observed, from the above definition of scepticism, that, as has already been stated, it is not the business of the thorough-going doubter to play the sceptic in the most absolute sense; on the contrary, he accepts of the phenomena of nature as he finds them, and, trusting to his instincts, he rests his practical life upon this empirical basis, and eschews altogether the dogmatical folly of perpetually pursuing that which he can never attain. The dogmatist tries to find a speculative criterion by which to test his philosophizings; while the sceptic, who fancies he

⁴ The edition of Sextus employed in this article is *Sexti Empirici Opera* of Jo. Albertus Fabricius, Lipsiæ, 1 vol. folio, 1718.

⁵ The passage stands thus:—*Ἐστὶ δὲ ἡ σκεπτικὴ δύναμις, ἀντιστικτικὴ φαινόμενων τε καὶ νοούμενων καὶ ὅλον ἀπαρξίαν ἀφ' ἧς ἐκχόμεθα διὰ τῆς ἐν ταῖς ἀντικειμέναις πράγμασι καὶ λόγοις ἰσοσθένειας τὸ μὴ πρότερον εἰς ἐποχὴν τὸ δὲ μετὰ τοῦτο εἰς ἀπαρξίαν.* (*Pyrrhon. Hypotypos.*, lib. i., cap. 4.)

Scepticism. has a thorough conviction of the fruitlessness of all such attempts, chooses to repose in his practical security, and leaves the dogmatist unaided to pursue his vain wanderings in search of his darling *ignis fatuus*. On this point Sextus is very explicit. "When," he says, "we inquire whether an object is such as it appears, we grant the appearance of it: we do not inquire and hesitate concerning what appears, but concerning what is said of this appearance." (*Pyrrh. Hypotyp.*, L. i., c. x.) The sceptic's conviction of the impossibility of finding a criterion of truth results from a multitude of considerations, all of which may be referred to the following three heads:—1. The subject of knowledge; 2. The object of knowledge; 3. The relation of subject and object, or from knowledge itself. Sextus Empiricus has chosen to follow a much more complicated order, but all his more important considerations will be found included under these three divisions.

No criterion of truth.

1. As to the sceptical contradictions which are found to emerge from a contemplation of the knowing mind or *subject* of knowledge, the first and most obtrusive are to be found in the region of Sensation, and the last and most recondite in the sphere of Intelligence. Phenomena are apprehended by the former faculties, Substances by the latter. Now, not only are those faculties found to disagree in themselves; they are found also to contradict one another. Not only do the results which the Senses supply contradict each other; these same results clash with those furnished by the Intelligence, which in turn are found to be mutually exclusive. The knowledge furnished by Sensation is as fallacious as it is patent. No one doubts that each separate sense affords at different times very different representations of the same object,—nay, are, and must be, diverse in their information at every different moment of time. Again, the senses themselves contradict one another as to the accuracy of their intelligence. Who can assure us, moreover, that the eye, ear, and touch of each separate individual affords him sensations exactly similar to ours? How do I know, for example, that what appears to me red, may not be felt by my neighbour to be yellow? Doubtless he would use the word *red* exactly as I do; but the puzzle is, does he mean precisely the same thing by it? For aught we know, the senses may be quite peculiar in each individual, and may give quite different reports to different men. What shall we say, then, of the accuracy of external observation, seeing that it is upon such testimony that the greater portion of it must rest? Human Sensations are modified by organization, by the distance of objects, by the physical and moral changes which take place in man, according as he is asleep or awake, in infancy or old age, in motion or at rest, pre-occupied with love or hatred, with joy or sorrow. And who is there can discover the means of rectifying such inevitable mistakes? Who will furnish man with a sensational criterion? The task is hopelessly in vain. The natural inference for the sceptic is of course *ἐπέχω*, or, I suspend my judgment.

But again, Sextus strives to find a basis for his doubt in the elements of the intelligence, and particularly in Logic and in logical phenomena. Let it not be supposed that a sceptic will be prepared to pass by any truth which is alleged to bear the special marks of an original conviction. It matters not how augustly these principles, affirmed to be *à priori*, may be ushered in, or with what profound reverence we would call upon men to fall down and worship when what is called a *primary truth* is unveiled in their presence; the sceptic replies calmly, as is his wont, that he must have evidence ere he bows down before those awful beliefs, warranting, nay, compelling him in a sort, to affix to them his unhesitating assent. Sextus takes a somewhat easier road to his doubt, and leads a proof of the radical falsehood

of those beliefs which we call original, by a simple reference to the various and equivocal representation which they have received at the hands of the dogmatists, real and apparent. And in doing so, unfortunately, his task was easy. He finds little difficulty, for example, in evolving discrepancies connected with the idea of Cause, which philosophers have since grappled with, and grappled in vain. But here he simply chronicled the labours of his predecessor *Ænesidemus*. "For," he remarks, "if we cannot understand a cause before its effect, seeing that it is relative; and if it is necessary to understand it as being before the effect, seeing that it is the cause of that effect; then it is quite impossible to understand anything to be before that which we cannot understand anything to be, and hence it is impossible to understand that there is a cause." The only respectable attempt made by philosophers, either ancient or modern, to solve this difficulty of the identity of Cause and Effect is that of Sir William Hamilton, and it may fairly be questioned whether that illustrious thinker has succeeded in unveiling the mystery which generated the ingenious quibble of the subtle old sceptic.¹ Having so far disposed of the data of consciousness, Sextus next directs his doubt against the faculties of Demonstration. And in combating Logic, he boldly affirms that "it may not exist." (*Pyrrh. Hypot.*, Lib. ii., c. 13.) He shows with much acuteness that demonstration never adds anything to the quantum of thought; but he does not succeed in disentangling the *form* from the *matter* of thought in the demonstrative process. Seeing that there is nothing but the evolution of identical propositions, so long as we choose to employ the method of demonstration, he at once sets the process aside as quite useless, or at least very doubtful; and in this his example has subsequently been followed by more than one philosopher who professed a very different creed. Sextus concludes thus:—"If these things which we have advanced in favour of demonstration be like the truth (for we do not at all oppose them), and if the arguments which we have advanced against demonstration be like the truth, we ought to arrest our judgment both for and against, and should say it is equally uncertain whether there is or is not any demonstration." (Lib. ii., c. 13.) So far the Subject of knowledge.

2. Scepticism may be inferred from the endless contradictions which emerge upon an examination of the *object* of knowledge. The object of knowledge is composed of phenomena and noumena. The former we apprehend through our faculties of observation, the latter we apprehend through the higher faculties of intelligence. In the first place, every object is in relation to some other or others; and hence, in order to comprehend the part, we would require previously to comprehend the whole. But this is impossible. Again, in external perception no object is apprehended by itself, and out of relation to a representing medium. However anxious we may be to seize upon the real object, the intervening medium perpetually presents itself. This Sextus, and all subsequent philosophers till Dr Thomas Reid, implicitly inferred from the principle first explicitly enounced by Empedocles, that "the relation of knowledge inferred an analogy of existence." A word on the second head of this subject; and to take a single example from one of the higher existences which human intelligence is affirmed capable of apprehending. Sextus opens his third book with a chapter on "God," towards the close of which he calmly expresses the following sentiment:—"Hence we also conclude that perhaps those who say there is a God cannot be excused from impiety; for in affirming that he exercises a providential care over all things, they say that he is the author of evil; and if they say that his providence extends only to some

¹ See the Eighth Opinion regarding Causality in Appendix i. to his *Discussions on Philosophy*, second edition.

Scepticism. things and not to all, they will be forced to confess that God is either envious or weak, all of which cannot be said without manifest impiety." The doubt which is thus generated by the heathen strikes at the very idea of a God. Proofs *à priori* and *à posteriori*, piled up like Ossa upon Pelion, would avail little against such an opponent.

3. Advancing to the third head, it becomes manifest from what has been affirmed of its constituents, the subject and the object of knowledge, that when they enter into relation, and form *knowledge*, this result must partake more or less of the character of its factors. Scepticism has already emerged from an examination of the subject and the object of knowledge, and it can hardly be supposed to be eliminated by bringing them into correlation. The incompleteness and inconsistency of knowledge render it for ever a favourite butt for those who are sceptically inclined.

To his general arguments against the leading principles of the dogmatists, Sextus added some special arguments against various of their theories, which we need not here examine. We shall add a word as to the manner in which he acquitted himself of his task.

Estimate
of the
Scepticism
of Sextus.

That Sextus Empiricus was a sceptic in reality, as he was certainly in name, no one will be prepared to deny. That he proved his right to the title also, by proving his right to doubt, we are likewise prepared to admit. The dogmatists, one and all, quailed under the open blows which he dealt at their laboured edifice, and many of those blows unhappily took effect. Amid constant marks of acuteness, he occasionally betrays an ingenuity worse than frivolous, and now and then misses the real question by his fondness for logomachy. But from this criticism Sextus Empiricus could possibly shield himself by taking refuge in his historical calling. And from this position we are not anxious to dive him, as the remark very likely applies as much to his school as to himself. Were we to trust for the veracity of consciousness to the development which it received from the philosophers previous to Sextus, all thinking men would infallibly be sceptical. For a positive proof of falsehood in one particular datum of consciousness is sufficient to establish, on the principle *falsus in uno, falsus in omnibus*, a presumption of probable falsehood in them all. More than one supposed datum of internal experience had been convicted of falsehood, and the Dogmatists, and not Human Nature, stood chargeable with the offence.

Scepticism
from Sextus
to
Hume.

With Sextus Empiricus the lists of Scepticism close for many centuries. The next to whom they shall be opened is to David Hume, the last and unquestionably the greatest of either ancient or modern sceptics. No name of any great lustre intervenes to fill up the long blank of sixteen centuries from Sextus to Hume. Practically, no doubt, many men like Montaigne (1533-1592) adhered to the sceptical creed. But they were in general either too wise to publish their opinions to the world, or too wary to let it know how they thought: When they gained boldness to let the world look on their views they for the most part strove to diminish any savour of odium which might be supposed to attach to a Pyrrhonist, by professing, at the conclusion of their speculations, the very greatest reverence for the Holy Scriptures. That this reverence was sometimes real, however inconsequent, cannot be denied. It was doubtless so in the case of La Mothe le Vayer, a French author of great learning and judgment (1586-1672), who openly professed Scepticism in favour of Religion. The same may be said of his disciples Sorbière (1615-1670) and Foucher (1644-1696); of Hirnhaym (died in 1679); of Huet (1630-1721); and of Joseph Glanvill, an Englishman (1636-1680), who may be regarded as the predecessor of Hume. One cannot speak so confidently of Charron (1541-1603), who was a disciple of Montaigne; of Sanchez or Sanctius, a Spaniard by birth, who professed medicine

and philosophy at Toulouse till the time of his death in Scepticism. 1632; and of the celebrated P. Bayle (1647-1706). That these writers were at bottom genuine sceptics can hardly admit of a doubt. We should certainly have had to chronicle many names which now are forgotten, or which never were heard of, had not the Inquisition spread terror over the free thought and free expression of Europe during the middle ages. But the device, of fancying that men were never safe so long as they trusted a whit to their Reason—that they must discard this faculty as repugnant in the highest sense to that superior faculty of divine Faith which is conferred immediately by the Spirit of God, has been exceedingly common in the various Christian schools of theology. It is thus that Scepticism, during many centuries, has been called in to support the Roman Catholic religion, and its advocates have supposed that by sapping the entire intellectual convictions of their fellows, they should thereby advance in the highest degree the eternal interests of their souls.

The scepticism of Hume (1711-76) was beyond all Scepticism of David Hume. question the most thorough and wide-reaching that philosophy had yet witnessed. He reduced philosophers to such straits that they were compelled either to refute his arguments (a thing not to be thought of upon his own principles), or ruefully to confess the vanity of their pursuits and the consequent folly of their lives. His *Treatise of Human Nature* was published in 1738, when Hume was in his twenty-seventh year. A book written by so young a man, with such marvellous acuteness and solidity of thought, displaying such a mastery over the difficulties of style, and such singular control over his own passions, was quite as unparalleled in the history of philosophy as the doctrines which it put forth were novel and alarming. Of the host of assailants which the book ultimately called forth, unquestionably the most respectable was Dr Thomas Reid. But so profoundly had the great sceptic meditated his task, and with such wondrous skill had he entrenched himself over the *débris* of all previous systems of philosophy, that Reid, who was not his match either in subtlety or in comprehension of thought, assailed Hume at first in a somewhat clumsy manner, and really missed the point of the very method which the Pyrrhonist had chosen. This method was no other than that of Pyrrho and the old sceptical school of Greece. Sextus Empiricus starts by the admission of phenomena, and proceeds to hew down all else which the dogmatists had raised; David Hume starts with the popular theory of experience, then so much vaunted by philosophers, and proceeds with surprising coolness to mow down every intellectual up-growth for which his theory was not capable of accounting. In open argument, in candid statement, and in solid attack, the Scottish sceptic is greatly in advance of the earlier Pyrrhonists of Greece. He is in a great measure free from that ingenious jugglery and conscious or unconscious sophistry with which the older sceptics are so justly chargeable. He seldom allows his logic to degenerate into logomachy, and very rarely substitutes a parallogism for a sound argument. To assure the reader of his genuine position, Hume takes pains to inform him as follows:—"Should it here be asked me," he says, "whether I sincerely assent to this argument, which I seem to take such pains to inculcate, and whether I be really one of those sceptics who hold that all is uncertain, and that our judgment is not in *any* thing possessed of *any* measure of truth and falsehood, I should reply, that this question is entirely superfluous, and that neither I nor any other person was ever sincerely and constantly of that opinion. Nature, by an absolute and uncontrollable necessity, has determined us to judge as well as to breathe and feel; nor can we any more forbear viewing certain objects in a stronger and fuller light, upon account of their customary connection with a present im-

Scepticism. pression, than we can hinder ourselves from thinking as long as we are awake, or seeing the surrounding bodies when we turn our eyes towards them in broad sunshine. Whoever has taken the pains to refute the cavils of this *total* scepticism, has really disputed without an antagonist, and endeavoured by arguments to establish a faculty which nature has antecedently implanted in the mind and rendered unavoidable." (Part iv., § 1.) Locke and the sensualists had furnished Hume with the theory of experience, on which they had endeavoured to found all knowledge. "'Tis therefore," he informs us, "by experience only that we can infer the existence of one object from that of another." (Part iii., § 6.) Knowledge, according to him, had its origin in "impressions and ideas," meaning by the former "all our sensations, passions, and emotions as they make their first appearance in the soul," and by the latter "the faint images of these in thinking and reasoning." Knowledge was accordingly reduced in the last analysis to Sensation from which to derive all its elements, simple and complex. "Now, since nothing is ever present," writes Hume, "to the mind but perceptions, and since all ideas are derived from something antecedently present to the mind, it follows that 'tis impossible for us so much as to conceive or form an idea of anything specifically different from ideas and impressions." (Part ii., § 6.) This being posited, the work afterwards is comparatively easy. Our ideas of space and time he strips of their infinity, and as products of sense, are reduced, the one to visible and tangible extension, the other to an observed succession or simultaneousness of objects. Personal identity he shows to be a mere imagination of the philosophers. "It must," he reasons, "be some one impression that gives rise to every real idea. But self or person is not any one impression. It cannot therefore be from any of these that the idea of self is derived, and consequently there is no such idea." (Part iv., § 6.) His theory of Causation, on the refutation of which so much needless philosophical acumen has been expended, when examined closely, reduces itself to these very narrow limits. "We have no other notion of cause and effect," he tells us, "but that of certain objects which have been *always conjoined* together, and which in all past instances have been found inseparable." The theory was not new to philosophy, whatever it might be to Hume. It had been signalized before, to confine ourselves to British philosophers, both by Glanvill and by Hobbes; but whether or not Hume had the merit of discovering the doctrine, we must at least attribute to him the credit of having first awakened the zeal of philosophers towards the theory. It will be observed that, so far from ascribing anything to that alleged character of *power* which resides in every cause, he attributes the existence of such an idea to "a popular habit or custom." He could find no warrant for such an idea in the compass of his experience, and why should he adhere to it if it was not conformable to the basis of all his reasoning? "The mind," he tells us plainly, "feels no sentiment or inward impression from this succession of objects; consequently there is not in any single instance of cause and effect anything which can suggest the idea of power or necessary connection." (*Essays*, § 7.) Nothing can be more explicit than this. All substances, of whatever class, are on this theory simply foibles of the fancy—mere creatures of the imagination. Phenomena may now reign undisturbed in the safe enjoyment of a shadowy rule; the substances or noumena which had been contrived to sustain them being convicted of non-existence, must troop off like spectres at the approach of dawn. Advancing with the same stately tread among the moral judgments of men, the sceptic grinds down with relentless heel every vestige of a moral world beyond the mere sphere of sensations. The only rational motive for man is his personal interest; the only determining motive

is a necessary constraint upon his so-called free-will. But **Scepticism.** the sceptic is not content with treading down the intellectual and moral nature of man; he advances a step further, and prostrates his natural theology, by trying to prove that the belief in the existence of Deity is uncertain, as effected by the illegitimate exercise of the human faculties. (See *Dialogues*, 1779.) With this last word the sceptic has completed the writing of destruction to which he held dogmatism doomed. The edifice of human knowledge, from its most general proposition down to its minutest detail, here received its final blow. The last pillar on which it stood has now been wrenched from under it, and the whole philosophic world cannot hold it up. The sceptic, so far from regretting the results of his industry, regards the spectacle with some measure of satisfaction; but without relaxing into any very hilarious merriment, he turns, bows an adieu to Reason, and, hand in hand with Nature, goes on his way. "I dine," Hume tells us, "I play a game of backgammon, I converse and am merry with my friends; and when, after three or four hours' amusement I would return to these speculations, they appear so cold, and strained, and ridiculous, that I cannot find in my heart to enter into them any further." (Part iv., § 7.) And so Scepticism again triumphs, and Dogmatism goes to the wall.

A word in conclusion in behalf of Truth and Dogmatism. **Conclusion.** And in the first place, one must deplore the variation and error which stand recorded against philosophy in all ages, by the rashness or prejudice of its votaries, by which it has become a by-word in the mouth of the unthinking, and a subject of scorn to the sceptical. This can hardly be wondered at. Were the inquirer not driven towards speculation as by a blind original instinct, which finds itself gratified by the merest husks which nature knows, he should long ere now have consigned philosophy, with all her solemn splendours, to the outermost regions of the reign of night. But so long as man is born into the world to inquire, men will continue to speculate, and, thankful to nature for the bestowal of such a boon, be content, if the results of their investigations were merely to feel the refreshing gale which blows towards them from the distant fields of reality, to lie down with a wistful sigh, and dream of the world which is beyond, whose balmy breezes they have experienced, but on whose shores they are not destined to set foot. It is matter of congratulation, to all who love Truth, that this august object of desire stands serene above the high strifes of men, and remains a pure and everlasting possession to all who humbly and faithfully seek it. In the war which the sceptic wages he aims his weapons not so much against Truth as against her pretentious high priest, who, in his haste for his own honour more than for the glory of her to whom he has sworn fealty, has made haste to deliver the oracle before the goddess had granted the response. Thus it has ever been, that in a sceptical combat the attention of the wise is directed to the dogmatist and to the sceptic, as to the sole combatants. There has hitherto been no sceptic who has attempted to show, much less who has succeeded in demonstrating, that the primary facts of consciousness, either in themselves or in their necessary consequences, are mutually exclusive—are reciprocally repugnant. Philosophy accordingly remains as of old, untainted by the fierce struggles which have been waged within her borders; ready as of old to welcome to her shrine all of clean hands and of pure heart; satisfied that, while her forbearance has been frequently converted into an encouragement of vanity, she possesses, nevertheless, the high prerogative of bestowing upon all her true worshippers the clear eye and the courageous heart. The crude Sensationalism which usurped the place of philosophy could hardly have been too rudely dethroned; and assuredly it met with as speedy a downfall as ever system knew.

Sceptre
Schadow.

Since Hume, the Scottish school can boast of Reid, Stewart, and Hamilton; the French of Royer Collard, Jouffroy, and Cousin; the Germans of Kant, Fichte, Hegel, and Schelling. The Scottish philosophers, who have generally been accused of timidity, have striven hard to erect a bulwark around our original beliefs which should defy all sceptical assault. The French, much more brilliant than either of their neighbours, have borrowed from them nearly all that is of much value in their Eclecticism. The German speculators have sought truth in a much more

profound and also in a much more profitless manner than Schaffhausen. They have pursued philosophy much beyond the verge of the romantic, and have exposed it to every possible evil. That which in the hands of Kant was meant to repel the Scepticism of Hume and the Sensationalism of Locke, in its turn produced a Scepticism as real as that which it had replaced, and grew under the hands of Hegel and Schelling into a wild agglomeration of Pantheism, in which no man can believe, because, it is said, no man can understand. (J. D.—s.)

SCEPTRE (*σκήπτρον*, a staff), was originally a wooden staff or support for the aged and infirm, and in course of time came to signify also a weapon of defence and assault; and from the privilege of habitually carrying it, it became emblematic of authority and station. The ancient Greek authors represent the sceptre as belonging more appropriately to kings, princes, and leaders of the people; but it was likewise borne by judges, heralds, priests, and seers. The transmission of the sceptre from father to son denoted the transfer of authority from the one member of a family to the other. The original wooden staff became, in consequence, a highly emblematic, and, of course, also a highly ornamental instrument. It was sometimes pierced with gold and silver studs, sometimes it was enriched with gems and ivory. The Roman kings and Roman consuls bore an ivory sceptre; and their divinities, Jupiter and Juno, as sovereigns over the rest of the deities, were represented with a sceptre, in token of their supreme authority. (Homer, *Iliad*, xviii. 416; ii. 46, 186, etc.; and i. 246.)

SCHADOW, JOHANN GOTTFRIED, an eminent sculptor of Germany, was born of poor parents, at Berlin, in 1764. Having made an elopement in his 21st year, his father-in-law subsequently forgave him, and furnished him with the means of proceeding to Italy, where he remained, diligently engaged in the study of the antique, till 1788. The first work of importance which came from his chisel after his return to Berlin, was the monument to Count Van-der-Mark, erected in 1790, in the Church of St Dorothy, at Berlin. Schadow was one of the first of his countrymen to break through the classic conventionalisms of his predecessors, and was one of the earliest to discover the dignified simplicity and natural elegance which slumbered behind those fixed classical forms. He put forth all his genius upon portraits, and it came back to him in ever-increasing reputation. He was appointed professor in the Academy of the Fine Arts at Berlin, in 1788, and its director-in-chief in 1822. A very large proportion of the best sculptors of the day, in Germany, were pupils of Schadow's. There were Rauch and Tieck, of Berlin; Dannecker, of Stuttgart; Zauner, of Vienna; Ruhl, of Cassel; and Pozzi, of Mannheim, all learned to handle the chisel under his eye. He died at Berlin, on the 25th of January 1850, aged 86.

The best works of Schadow are his equestrian statue of Frederick the Great, at Stettin; General Ziethen; Field-Marshal Blucher, at Rostock; General Tauenstein, at Breslau; Duke Leopold of Dessau, at Berlin; Luther, at Wittenberg; a colossal group, in marble, of Queen Louise of Prussia, and her sister, the Duchess of Cumberland; and the quadriga on the Brandenburg Gate, at Berlin. He likewise wrote the following works:—*Wittenberg's Denkmaler der Bildnerlei, Baukunst und Malerei*, etc., 1825; *Polyphet*, etc., Berlin, 1834; *Nationalphysiognomien*, etc., Berlin, 1835.

Rudolf, the eldest son of Schadow, born in 1785, and died at Rome in 1822, displayed decided genius in his father's art. Friedrich-Wilhelm, who was in 1843 ennobled by the King of Prussia, was Schadow's second son, and has gained for himself a great reputation as a historical and portrait painter.

SCHAFFHAUSEN, a canton of Switzerland, the most northerly and also one of the smallest of the whole; bounded E., N., and W. by the grand-duchy of Baden, S. by the cantons of Zurich and Thurgau. It is divided by Baden into three portions; the largest of which lies farthest north, another to the south, and a third to the east of it. The southern boundary of all three is formed by the Rhine; on the other side there is no natural limit. Total area, 115 square miles. The surface is very rugged, though it can hardly be called mountainous, as there are no very high elevations. Several ridges of hills, ramifications of the Jura range, traverse the country from S.W. to N.E. These have, in general, a gradual slope towards the Rhine, but on the other side the declivities are steeper. Numerous long and narrow valleys stretch towards the Rhine, but nowhere do they open out into plains. The highest summit in the canton is the Randenberg, 2957 feet above the sea. Except the Rhine, which receives the whole drainage, there are no important rivers; but limpid rivulets abundantly water the land. The geological formation that is most prevalent is that of Jura limestone. Iron is obtained in considerable abundance, and is smelted at Laufen, on the Rhine. Gypsum, alabaster, and sandstone, are the only other important minerals. The soil is generally fertile, and the climate milder here than in most parts of Switzerland. Agriculture forms the occupation of the most of the people. In 1854 Schaffhausen contained 31,000 acres of arable land, 3100 of vineyards, 7058 of meadows and pasture land, 27,300 of forests, and 7000 of waste land. In the same year there were 1416 houses, 8726 horned cattle, 483 sheep, 2864 goats, and 748 swine. Few manufactures are carried on here, the chief being tanning, cotton-spinning, and distilling cherry-water. Some steel and hardware are also fabricated. A considerable transit trade is carried on through the canton, especially by the Rhine. The constitution of the canton is democratic; the electoral franchise being possessed by all citizens above twenty, with the exception of paupers, bankrupts, and criminals. The legislature consists of a great council of seventy-eight members, popularly elected; who appoint a smaller or executive council of nine members, at the head of whom stands a burgomaster. Both councils exist only for four years. Education is well attended to, there being a lyceum in the capital, and numerous elementary schools throughout the country. Schaffhausen is divided into six districts, but there are only three towns of any importance—Schaffhausen, the capital, Neunkirch, and Stein. The inhabitants are of German origin, and for the most part profess the reformed religion. Pop. (1850) 35,300; of whom 33,889 belong to the Reformed, and 1411 to the Roman Catholic Church.

SCHAFFHAUSEN, the capital of the above canton, on the side of a hill on the right bank of the Rhine, 24 miles N. of Zurich. It stands just at the place where the rapids and falls of the river render it unnavigable as far as Basle; and owes its origin, as well as its name, to the boat or skiff-houses that were built here for the lading and unlading of boats on the river. It is protected by walls and tower; and on the hill above stands an old feudal castle, with bomb-proof casemates. Schaffhausen is one of the most antique-look-

Schalken
||
Scheele.

ing towns in Switzerland; it has irregular streets, and many houses with their fronts and oriel-windows curiously carved. The chief public buildings are the Romanesque cathedral, of a cruciform shape, with a lofty tower; the large church of St John; the town-hall; and the arsenal. The principal manufactures of the place are silk, cotton, and steel; and there is a considerable trade with Germany. It is much resorted to by travellers, on account of its vicinity to the celebrated falls of the Rhine at Laufen, the finest cataract in Europe. The Rhine is crossed here by a wooden bridge of ordinary construction, which replaces the celebrated single-arched one of 365 feet in span, that was burned by the French in 1799. Schaffhausen was the birthplace of the Swiss historian, Müller. Pop. 7700.

SCHALKEN, GODFREY, was born at Dort, in 1643, and pursued his studies as a painter under Hoogstraten, and subsequently under Gerard Douw. He was esteemed one of Douw's best pupils, but his talent was rather mechanical than creative. This was visibly displayed in his attempts to imitate the bold contrasts of light and shade of Rembrandt. Having failed to represent sunlight, he had recourse to candle-light, in which he had more success. Some of his daylight pieces, however, display a great degree of care. He was patronised by William III. of England, who induced him to come over and settle in London, where he painted the portrait of his Majesty and several of the nobility. He returned to Holland, settled at the Hague, and died in 1706. There are three good paintings by Schalken in the Royal Collection, and one in the National Gallery of England.

SCHASSBURG (Magyar, *Segesvar*), a town of the Austrian empire, in Transylvania, 42 miles N.E. of Hermannstadt. It stands partly on a hill and partly in a valley, on the Great Kokel; and contains an ancient castle, a Franciscan convent, Roman Catholic and Protestant churches, and a Protestant gymnasium. Cotton, woollen, and linen cloth are made here; and wine and vegetables are produced in the neighbourhood. Near Schassburg the Hungarian insurgents were defeated July 31, 1849. Pop. 6900.

SCHAUMBURG-LIPPE. See LIPPE-SCHAUMBURG.

SCHEELE, CHARLES WILLIAM, was born on the 19th of December 1742, at Stralsund, where his father had kept a shop. At a very early age he showed a strong desire to follow the profession of an apothecary, and he was accordingly apprenticed to one Bauch at Gottenburg. Among the various books which he read that treated of chemical subjects, Kunckell's *Laboratory* seems to have been his favourite. He used to repeat many of the experiments contained in that work privately in the night, when the rest of the family had retired to rest. After Scheele's departure from Gottenburg in the year 1765, he served successively at Malmö, at Stockholm, and at Upsal. At the latter place he happily commenced the friendship which subsisted between him and Bergman. During his residence at this place, Prince Henry of Prussia, accompanied by the Duke of Sudermania, visited Upsal, and chose this opportunity to see the academical laboratory. Scheele was accordingly appointed by the university to exhibit to them some chemical experiments. This office he undertook, and showed some of the most curious processes in chemistry. The two princes asked him many questions, and expressed their approbation of the answers which he returned to them. The duke asked him of what country he was, and seemed to be much pleased when Scheele informed him that he was born at Stralsund. On their departure they told the professor, who was present, that they should esteem it a favour if he would permit the young man to have free access to the laboratory as often as he chose to make experiments. In the year 1777 Scheele was appointed by the medical college to be apothecary at Koping. It was at that place that he soon

showed the world how great a man he was, and that no place or situation could confine his abilities. When he was at Stockholm he showed his acuteness as a chemist, as he discovered there the new and wonderful acid contained in the fluor spar. It has been confidently asserted that Scheele was the first who discovered the nature of the aeril acid, and that whilst he was at Upsal he made many experiments to prove its properties. This circumstance might probably have furnished Bergman with the means of treating this subject more fully. At the same place he began the series of excellent experiments on that remarkable mineral substance manganese; from which investigation he was led to make the very valuable and interesting discovery of oxymuriatic acid. At the same time he examined the properties of ponderous earth. At Koping he finished his *Dissertation on Air and Fire*; a work which the celebrated Bergman most warmly recommended in the friendly preface which he wrote for it. The theory which Scheele endeavours to prove in this treatise is, that fire consists of pure air and phlogiston. The author's merit in this work, exclusive of the encomiums of Bergman, was sufficient to obtain the approbation of the public; as the ingenuity displayed in treating so delicate a subject, and the many new and valuable observations which are dispersed through the treatise, justly entitled the author to that fame which his book procured him. The English translation was executed by Kirwan.

Scheele now diligently employed himself in contributing to the Transactions of the Academy at Stockholm. He first pointed out a new way to prepare the salt of benzoin. In the same year he discovered that arsenic, freed in a particular manner from phlogiston, partakes of all the properties of an acid, and has its peculiar affinities to other substances. In a *Dissertation on Flint, Clay, and Alum*, he clearly overturned Beaumé's opinion of the identity of the siliceous and argillaceous earths. He likewise published an *Analysis of the Human Calculus*. He showed also a mode of preparing *mercurius dulcis* in the humid way, and improved the process of making the powder of algaroth. Having analysed the mineral substance called molybdena, or flexible black-lead, he discovered a beautiful green pigment, and showed us how to decompose the air of the atmosphere. He discovered that some neutral salts are decomposed by lime and iron, and he decomposed plumbago, or the common black-lead. After observing, with peculiar ingenuity, an acid in milk, which decomposes acetated alkali; he, in his experiments on the sugar of milk, discovered another acid, different in some respects from the above-mentioned acids and the common acid of sugar. He accomplished the decomposition of tungsten, the component parts of which were before unknown, and found in it a peculiar metallic acid united to lime. Having published an excellent dissertation on the different sorts of ether, he found out an easy way to preserve vinegar for many years. His investigation of the colouring matter in Prussian blue, the means he employed to separate it, and his discovery that alkali, sal ammoniac, and charcoal, mixed together, will produce it, are strong marks of his penetration and genius. He found out a peculiar sweet matter in expressed oils after they have been boiled with litharge and water, and showed how the acid of lemons may be obtained in crystals. He found the white powder in rhubarb, which Model thought to be selenite, and which amounts to one-seventh of the weight of the root, to be calcareous earth united to the acid of sorrel. This suggested to him the examination of the acid of sorrel. He precipitated acetate of lead with it, and decomposed the precipitate thus obtained by the vitriolic acid, and by this process he obtained the common acid of sugar; and by slowly dropping a solution of fixed alkali into a solution of the acid of sugar, he regenerated the acid of sorrel. From his examination of the acids contained in fruits and berries,

Scheele.

Schee-
maker.

he found not one species of acid alone, viz., the acid of lemon, but also another, which he denominated the malaceous or malic acid, from its being found in the greatest quantity in apples.

By the decomposition of Bergman's new metal, siderite, he showed the truth of Meyer's and Klaproth's conjecture concerning it. He boiled the calx of siderite with alkali of tartar, and precipitated nitrate of mercury by the middle salt which he obtained by this operation. The calx of mercury which was precipitated was found to be united to the acid of phosphorus, so that he demonstrates that this calx was phosphoretted iron. He found also that the native Prussian blue contained the same acid. He discovered, by the same means, that the perlate acid, as it was called, was not an acid *sui generis*, but the phosphoric united to a small quantity of the mineral alkali. He suggested an improvement in the process for obtaining magnesia from Epsom salts; and he advises the adding of an equal weight of common salt to the Epsom salt, so that an equal weight of Glauber's salt may be obtained; but this will not succeed unless during the cold of winter. These are the valuable discoveries of this great philosopher, which are to be found in the *Transactions of the Royal Society*, at Stockholm. Most of his essays have been published in French by Madame Picardet and M. Morveau, of Dijon. Dr Beddoes also has made a very valuable present to his countrymen of an English translation of a great part of Scheele's dissertations, to which he has added some useful and ingenious notes.

Viewing Scheele as a philosopher, we must judge of him from his many and important discoveries. What concerns him as a man we are informed of by his friends, who affirm that his moral character was irreproachable. It was matter of remark, that his chemical apparatus was neither neat nor convenient; his laboratory was small and confined; nor was he particular in regard to the vessels which he employed in his experiments, so that we may justly wonder how such discoveries and such experiments could have been made. He understood none of the modern languages except the German and Swedish; and he had not the advantage of being benefited by the early intelligence of discoveries made by foreigners, but was forced to wait till the intelligence was conveyed to him in the slow and uncertain channel of translation.

It was often wished that he would quit his retirement at Koping, and move in a larger sphere. It was suggested to him that a place might be procured in England, which might afford him a good income and more leisure; and indeed latterly an offer was made to him of an annuity of L.300 if he would settle in this country. But death put an end to this project. For half a year before this melancholy event his health had been declining, and he himself was sensible that he would not recover. On the 19th of May 1786 he was confined to his bed; on the 21st he bequeathed all of which he was possessed to his wife, who was the widow of his predecessor at Koping, and whom he had lately married; and on the same day he departed this life. Thus, in less than two years, the world lost Bergman and Scheele, of whom Sweden may justly boast, as philosophers who were beloved and lamented by all their contemporaries, and whose memory posterity will never cease to revere.

SCHUEEMAKER, SCHUEEMAKERS, SCHUMAKER, or SCHUMACIER, PETER, a Flemish sculptor, who obtained considerable celebrity in England during the Rysbrack and Roubiliac period of sculpture, was born at Antwerp in 1691. He received his early instructions from his father and from a sculptor named Delvaux. In his youth he visited Denmark, and made a pilgrimage to Rome, which he performed on foot. He afterwards resolved to go to England, and performed a great part of that journey likewise on foot. He paid a second visit to Rome, and again settled in Eng-

VOL. XIX.

land in 1735. He lived first in Old Palace Yard, and subsequently in Vine Street, Piccadilly, where he was employed on numerous important works, particularly the monuments of Westminster Abbey. The time of his death is not known, but it must have been subsequent to 1770, the year of his return to Antwerp.

As a sculpture Scheemaker did not stand exceedingly high, although he was capable of rivalling Rysbrack and Roubiliac. He was an excellent designer, and managed well his elaborate costumes; but he rarely or never rose to any of the higher qualities of his art. In Westminster Abbey there are monuments by him to Shakspeare; Dryden; George, Duke of Albemarle; John Sheffield, Duke of Buckingham, &c. He likewise executed numerous busts and other pieces of sculpture.

SCHUEFFER, ARX, an eminent French historical painter, was born at Dordrecht, in Holland, of French parents, in 1794 or 1795. He studied art under Baron Guerin at Paris, and practised historical and genre painting in that city with very great success. His progress has been, with few exceptions, steadily upwards from 1812, when he exhibited his "Abel and Tuza singing the praises of the Lord," down to his latest work in 1858. Among his most famous pictures are his Goethe's "Faust" and "Margaret," (1831-34); "Francesca da Rimini and her Lover meeting Dante and Virgil in Hell" (1835); "Christ the Comforter" (1836); Goethe's "Mignon," and a "Dead Christ" (1837-1845); "Dante and Beatrice" (1849), &c. He has likewise executed some excellent portraits, among which may be mentioned his La Fayette, Talleyrand, Beranger, Lamartine, Queen Amelie, and Charles Dickens.

Scheffer combines in his pictures many of the excellencies both of the German and French schools, and a few of the defects of both. In turn of thought and manner, for example, he is decidedly German, while in style and colour he is more obviously French, being often rich and beautiful, but wanting in softness and truth. Scheffer is, beyond doubt, a great painter, and many of his works leave but little to desire. He is looked up to, and with reason, by his countrymen as a master in devotional art; and he has fairly succeeded in breaking down that rigid classical conventionalism which so long had hedged in the French school of art. He is at times hurried and careless, though in his more elaborate pictures, he has put forth all the labour which time and genius could expend on them. He was made an officer of the Legion of Honour in 1825, and he was tutor to the family of Louis Philippe. He died on the 15th of June 1858.

Arnold Scheffer, who earned some distinction as a French political writer, and who died in 1853, was the younger brother of the painter; and Henri Scheffer, a younger brother still, and a painter of less note, still survives.

SCHUEFFER, JEAN, a learned antiquary, was born at Strasburg in 1621, of an ancient family, descended in a direct line, according to some, from Peter Schœffer, one of the inventors of the art of printing. (See PRINTING.) He made great progress in languages and in history; and at an early age he published, in 1643, a work of very great learning, *De Varietate Navium apud Veteres*. Meanwhile his native district of Alsace was frequently exposed to the license attendant on war, and Scheffer, anxious for a learned retirement, betook himself to Sweden, where Queen Christina took him by the hand, and obtained for him, in 1648, the chair of eloquence and of public law in the University of Upsala. Here he worked with surprising diligence till his death on the 26th of March 1679, at the age of fifty-eight.

Besides editing Ælian's *Varia Historia*, Phædrus, Arrian's *Tactica*, a newly discovered fragment of Petronius, Aphthonius, Hyginus, Justin, Julius Obsequens, and others, he likewise wrote numerous theses, harangues, eloges, and

4 x

Scheffer.

Scheid
||
Schéle-
stadt.

opuscula, besides seventeen distinct treatises which will be found in the 39th vol. of Nicéron and in the *Biographie Universelle*. His *Lapponia*, or History of Lapland, Frankfurt, 1673, has been translated into German, French, and English, Oxford, 1674. A Memoir of Scheffer, by Eric Michael Fant, professor of history at Stockholm, was honoured with the prize, in 1781, of the Society of Education of Upsala.

SCHEID, EVERARD, perhaps better known by his Latin name SCHEIDIUS, was a philologist of distinguished merits, who betrayed early a profound knowledge of the oriental languages, was born at Arnheim, in Holland, in 1742. He was, in 1768, appointed professor at Harderwyck, and on the death of J. Albert Schultens, he obtained the chair of oriental literature at Leyden, which he filled with distinguished ability. He died in 1795. Besides the *Minerva* of Francisco Sanchez, Scheid left other works, both original and edited, which still perpetuate his name. His most popular book was *Glossarium Arabico-Latinum Manuale*, being an abridgment of the Arabic Lexicon of James Golius, Leyden, 1769. He published besides, eight other works, which are to be found in the *Biographie Universelle*. There was projected by Scheid a new Dutch translation of the Bible, but he was prevented by death from carrying out his design.

SCHEINER, CHRISTOPH, a German mathematician and astronomer, eminent for being one of the first who discovered spots on the sun, was born at Schwaben, in the territory of Mundelheim, 1575. He first discovered spots on the sun's disk in 1611, a few months later than Galileo, and made observations on these phenomena at Rome, until at length reducing them to order, he published them in one volume folio in 1630. He wrote also some smaller pieces relating to mathematics and philosophy, invented the pantograph, and died in 1660.

SCHELDT, or SCHELDE (Fr. *Escaut*, Lat. *Scaldis*), a river of the Netherlands, issues from a small lake in the French department of Aisne, flows in an irregular course mostly N.E., through the department of Nord; enters the kingdom of Belgium, and traverses the provinces of Hainault and East Flanders. At Ghent, in the latter, it takes a sudden curve towards the east, and flowing between Antwerp and East Flanders, enters the Dutch territory below the city of Antwerp. Here it turns westwards, spreads itself out, and enters the sea by two broad estuaries; between which lie the islands of Walcheren and Beveland. Its whole length is about 200 miles, for nearly the whole of which it is navigable. Its principal affluents are the Haine, Dender, and Rupel, from the right; and the Scarpe and Lys from the left. Its commercial importance is very great, as it is connected by canals with the Somme, the Seine, and the Loire, while its estuaries communicate with the Meuse and Rhine, and lie directly opposite that of the Thames. In the lower part of its course the Scheldt is protected by dykes, as it traverses a very low and flat country.

SCHELESTADT, or SCHLESTADT, a fortified town of France, capital of an arrondissement, in the department of Bas-Rhin, on the left bank of the Ill, 26 miles S.W. of Strasburg. It has narrow, crooked, but clean streets, lined with irregular houses; and contains several fine churches and other buildings. The church of St George is a Gothic edifice of the fourteenth century; and St Foy is much more ancient, and is a copy of that of the Holy Sepulchre at Jerusalem. Near the latter is a large convent, now used for barracks. The chief other building is the court-house, once a Jesuit college. The fortifications are regular, the work of Vauban; and the place is entered by three gates. Flour, beer, vinegar, starch, leather, linen, and earthenware, are the chief manufactures of Schélestadt. There is some trade in these and other articles. Martin Bucer the reformer was born here. Pop. (1856) 9086.

SCHELLING, FRIEDRICH WILHELM JOSEPH VON, Schelling the last of the great German philosophers inaugurated by Kant, was born at Leonberg, in the kingdom of Würtemberg, on the 27th of January 1775. He studied theology at the University of Tübingen, where he had Hegel for his college companion, and with whom he formed a friendship which lasted for long years, but which had subsequently to give way before the bitterness of philosophic rivalry. Schelling, though the younger man, was the older philosopher, and he had the honour of indoctrinating Hegel in the sublime mysteries of subjective idealism. Schelling continued his studies at Leipzig and at Jena, whither he had been attracted by the eloquence of Fichte, and whom he afterwards succeeded, on the removal of his master in 1798. His friend Hegel rejoined him at Jena, and wrought in conjunction with him at the Jena *Zeitschrift*, in promulgating their then common doctrine. Schelling published three works in 1795, ere he had completed his twentieth year:—*Vom Ich als Princip der Philosophie* (Of the Ego as the Principle of Philosophy); *Philosophische Briefe über Dogmatismus und Criticismus* (Philosophical Letters on Dogmatism and Criticism); *Ueber die Möglichkeit einer Form der Philosophie überhaupt* (On the Possibility of a form of Philosophy in general). These works were followed by others in quick succession:—*Abhandlungen zur Erläuterung des Idealismus der Wissenschaftslehre* (Dissertations on the Idealism of the Theory of Science) appeared in 1796–97; *Ideen zu einer Philosophie der Natur* (Ideas for a Philosophy of Nature) 1797, second edition 1803; *Von der Weltseele* (On the Soul of the World) 1798, third edition 1809; *Erster Entwurf eines Systems der Naturphilosophie* (First Sketch of a System of the Philosophy of Nature) 1799; *Einleitung zu seinem Entwurf eines Systems*, &c. (Introduction to his Sketch of a System, &c.) 1799. When we reflect that those works were all written within the period of five years, we will not be inclined to find fault with the youthful philosopher for being too sluggish in the philosophic cause which he had espoused. The years which immediately preceded and which immediately succeeded the commencement of the century, constitute the most interesting epoch in the history of German philosophy. In 1802 Schelling graduated in medicine, and the following year quitted Jena, the principal centre of Protestant thought, for the Catholic university of Würzburg. He left Hegel to fill his shoes at the University of Jena, when this great dialectician began to forge a system of resolute logic, so wild and strange, that Germany, that land of chimeras, might have crowned him as the high priest of intellectual legerdemain. (See HEGEL.) In 1807 Schelling was appointed Member of the Academy of Sciences of Munich, and subsequently perpetual secretary of the Academy of the Fine Arts. Schelling continued still to ply his pen with untiring energy. For the next fifteen years he kept the printing-presses of Germany almost in constant operation, promulgating his transcendental philosophy. Hegel had now caught the ear of the German public with his "Logische Idee," and Schelling, in partial disgust, allowed the favourite to have his day. From 1815 till the day of his death, he wrote nothing of any importance. The following is a list of his works during this second period of his philosophical activity:—*Zeitschrift für die Speculative Physik*, containing a brief account of his system, under the title of *Darstellung meines Systems der Philosophie*, 2 vols., 1800–1803; *System des Transcendentalen Idealismus* (System of Transcendental Idealism) 1800, translated into French by Grunblot, Paris, 1842; *Bruno*, a dialogue on the divine and natural principle of things, 1802, in French, by Husson, Paris, 1845; *Neue Zeitschrift*, 1803; *Vorlesungen über die Methode des Akademischen Studiums* (Lectures upon the Method of Academic Studies), 1803, new edition, 1813; *Philosophie und Religion*, 1804; *Apho-*

Schelling. *rismen zur Einleitung in die Naturphilosophie* (Aphorisms for an Introduction to the Philosophy of Nature) 1806; *Ueber das Verhältniss des Realen und Idealen in der Natur* (On the Relation of the Real and the Ideal in Nature) 1806; *Darlegung des wahren Verhältnisses der Naturphilosophie zu der verbesserten Fichte'schen Lehre* (Exposition of the true relation of the Philosophy of Nature to the reformed doctrine of Fichte) 1806; *Ueber das Verhältniss der bildenden Künste zu der Natur* (Concerning the Relation of the Arts of Design to Nature) 1807; *Philosophische Untersuchungen über das Wesen der Menschlichen Freiheit* (Philosophical Researches on the Essence of Human Liberty) 1809; A reply to the accusations of Jacobi, entitled, *Denkmal der Schrift von den Gotthchen Dingen*, 1812; and *Die Gottheiten von Samothrake* (The Divinities of Samothrace) 1815. With the exception of his first lecture at Berlin in 1841 (*Erste Vorlesung in Berlin*), this work on the Divinities of Samothrace closed his published writings. In 1820 he retired to Erlangen, where he was ennobled by the King of Bavaria. On the creation of the University of Munich he was appointed to the chair of philosophy. He was afterwards chosen Chevalier of the Legion of Honour, and foreign associate of the Academy of Moral and Political Sciences of France. From 1841, when he was chosen professor in the University of Berlin, he elaborated in silence a new species of philosophy, which was to bear the name of the *positive* philosophy. This system he had not matured, or at least he had not given it to the public, when he died at Ragaz, in Switzerland, whither he had gone for the benefit of his health, in August 1854, at the age of seventy-nine.

Schelling never produced a definite system, and pursued his studies, as Hegel phrased it, "in the presence of the public." But it is necessary to add, that the public of Germany followed him with a lively interest, and the young and ardent writer exercised over it a very powerful influence. If he failed to expound his philosophy with a systematic precision, if he presented it under various guises, returning continually upon his former work, he in no case proved false to his own genius, and from first to last his works breathe out the same sublime spirit. When, in 1841, he made his first appearance before the public of Berlin, he could tell them, in his first lecture, without any sacrifice of truth, that he did not disavow the speculations of his youth. A man of genius cannot change his ideas as he changes his will; he is under their empire more than they are under his; his ideas belong to him in a more emphatic sense than he can be said to possess his ideas. Schelling is a philosopher in the largest sense of that term; and had he kept the intellectual rein more closely upon his Pegasus, he would doubtless have ranked with those sublime philosophers of which Plato is the acknowledged chief. He is a philosopher among poets, and a poet among philosophers. As he has frequently said, every system of philosophy, when it is pushed to the last source of intellectual inspiration, in its attempt to represent the physical and moral world, is not a poem in the highest sense of that word, does not adequately represent the universe, that vast and sublime poem, of which all philosophies, and all poems alike, are but the faint resemblances and imperfect imitations. His philosophical genius developed itself under the influence of the school of Kant and of Fichte, but he gave early indications of a tendency to soar over the heads of his instructors. He drank deeply at the fountain of the Neo-Platonists, of Giordano Bruno, and particularly of Spinoza; and arose from the draught, strong as a giant refreshed with wine, to weave the endless threads of his wandering thoughts into a web of idealistic pantheism.

The genuine philosophy of Schelling places him historically between Fichte and Hegel. It has never been presented by himself in a systematic form: he has proceeded

by adding fragment to fragment, without apparently heeding whether these were mutually exclusive or not. To say the truth, his mind was more under the government of the imagination than it was under law to the harder elements of the intelligence. The pure intellect was seldom permitted to shape out any proposition without being dazzled by the fiery light which the imagination threw upon it; so that, when he halted in his speculative course he could not calmly survey his work by reason of the brilliant and blinding glow which was cast over it by this subtle and potent agent. After all, however, considering the region in which he chose to move, it mattered very little which faculty of the mind predominated, where all its faculties would have been at fault. Schelling's great error lay in permitting his mind to be bewildered in the pursuit of a vain phantom, which arose only to lure him on, and which allowed itself to be apparently grasped, only to destroy its pursuer. We shall here limit ourselves, in characterizing his philosophy, to point out in a very general manner its leading thoughts and its principal results.

The ruling idea of Schelling's philosophy is *the identity of the Subject and Object of thought*, of the Ego and the Non-ego, of the ideal and the real; an identity which Fichte had only presented as an ideal which the Ego should continually endeavour to realize. While Fichte accorded to ideas only a subjective value, Schelling attributed to them an objective meaning. This objective something which the Ego contemplated was not, however, according to Schelling, anything external to the Ego and independent of it; on the contrary, it was precisely within the sphere of the Ego where this subject-object was found. He identified thought with things, and things with thought. According to him, Reason is one, and human reason is identical with divine reason. The ideas of the divine intelligence realize themselves in being thought; things, again, are their reflection, or phenomenal expression. Human intelligence conceives, by its own laws, these divine ideas; and human thought is a faithful transcript of the divine dialectics which produced the universe. There is thus a pre-established harmony between our ideas and external objects, which are but identical copies of the same model. By the *Intellectual Intuition* (*Anschauung*) which enables the spectator to disrobe himself of his manhood, and temporarily to become a god, he rises above the region of the understanding, and identifies his reason with the divine. Thus the true philosophical method consists in casting aside reflection, by whose sluggish movement things had been taken for real existences, independent of the subject of thought, and rising into the genuine philosophical *Intuition*, by which thought and things are perceived to be one, even as human reason is identified with the absolute. To show how all things emanate from the absolute, is what Schelling calls the method of *construction*. Things are, according to this system, but the expression of the absolute reason, which necessitates the total indifference of subjective and objective. The absolute, by its tendency to objectify itself, moves forward by an expansive law, and out of the abundance of the *natura naturans* comes the whole variety of the *natura naturata*. Again, by its tendency to subjectify itself, it moves backward, as it were, and by a contractive excitement, draws the *natura naturata* back upon the *natura naturans*, when it becomes conscious of itself. The creation of the universe, in short, or the evolution of the absolute, is an *act* of eternal knowledge, and philosophy is the free reproduction in the reflective consciousness of this act of knowledge. Whoever, according to Schelling, cannot elevate himself to this Intellectual Intuition, or philosophic ecstasy, is entirely incapable of philosophy, and there is no true philosophy which does not recognise this as its genuine foundation. There is a speculative rapture, as there is a poetical enthusiasm, and

Schelling.

philosophy is the most magnificent and the most sublime of poems.

The philosophy of the absolute, or of the All-one (*die Alleinslehre*), as it has been called, divides itself into transcendental idealism and the philosophy of nature. The whole is sometimes comprised under the general designation of the philosophy of nature, or absolute idealism. Absolute idealism thus includes relative idealism, or the philosophy of the ideal world; and the philosophy of nature, properly so called, comprises the philosophy of the visible world. The degrees of identical development of mind and of nature are called powers or potencies, and the potencies of these two parallel systems are absolutely contemporaneous. Transcendental philosophy and the philosophy of nature express two parallel series, each of which develops itself under the three potencies—of inorganic nature; of vegetable and animal life; and of conscious life. As the real world is divine knowledge, or the external manifestation which Deity has of his own thoughts, so philosophy is the knowledge of that knowledge. It is idealism in so far as it represents the ideal world; realism in so far as it represents the real world. But in so far as the sensible world is but an imperfect image of the intelligible world, it is thus far idealism in the most absolute sense. Besides the ideal world, as it exists in Deity, and as it is found by the intellectual intuition in the human reason, and the visible world or nature, its identical expression, there is yet another world to be recorded, the world of history. This third department, the product of our moral activity, and but another mode of active intuition, is the return of decayed ideas, so to speak, again to Deity, whose end is the final restoration of all things to the state of unity. Thus one sole and simple cause produces the real world and the world of ideas, of which the former exists without consciousness, and the latter exists with consciousness; and the same spirit which manifests itself in nature and in man, manifests itself also in history. It is by this third form of development that Deity realizes himself, and by it he brings back to himself the full and distinct consciousness of his own ideas. Deity, accordingly, manifests himself everywhere; in the mind, in nature, and in history. Absolute unity of substance lies beneath all the apparent forms of the world, as absolute unity of action works out all the developments of the universe. And thus the last threads of the web are woven, and man awakes to the discovery, that while he slept, he has been enveloped in a most subtle texture of idealistic pantheism. For a critical estimate of the system of Schelling, the reader is referred to the section on "Ontology," in the article *METAPHYSICS*, and especially to the masterly discussion of it in Sir William Hamilton's *Discussions on Philosophy*, p. 18.

The philosophy of Schelling has had numerous adherents, many of them men of the foremost reputation. Oken, Steffens, and G. H. Schubert have applied its principles to the natural sciences and to psychology; while others have applied them to æsthetics, to mythology, to history, and to religion. What was destructible in the philosophy has now well-nigh died out in Germany, while what was vital and fresh in it will grow and increase for ever. (J. D.—S.)

SCHEMNITZ, the principal mining town in Hungary, stands between two hills, in the county of Honth, 65 miles N. by W. of Buda. It is irregularly built on very uneven ground; and contains a mining academy, founded by Maria Theresa in 1760; and several other educational institutions. The gold and silver mines employ about 10,000 hands, and yield annually 300 lb. Troy of gold, and 43,400 of silver. The population of the town itself is only 8500; but including the adjacent villages, it amounts to 20,000.

SCHENECTADY, a town of the United States of North America, in the state of New York, on the right bank of the Mohawk, 16 miles N.W. of Albany. It is regularly

built; and contains several handsome churches, a town-hall, jail, lyceum, academy, and the Union College, which was founded in 1795, and contained, in 1857, 16 professors and teachers, 70 students, and a library of 17,000 volumes. It carries on several manufactures. The Erie Canal, which connects Lake Erie with the Hudson, passes through the town. Pop. (1850) 8921.

SCHERZO, a short musical composition, generally in 4 time, of a light and playful style. It is more rapid than the old minuet. Some excellent examples of the scherzo are to be found in Beethoven's works; among others, one in his second Symphony, op. 36, in D major.

SCHUEFFELIN, or **SCHAEUFFELEIN**, **HANS LEONARD**, a celebrated old German painter and wood-engraver, was born at Nürnberg about 1490. Hans was placed early with Albrecht Dürer, with whom he became a great favourite. A good painting by Schueffelin is his "Taking Down from the Cross," in Nordlingen, executed in 1521. He died at Nordlingen in 1539 or 1540.

SCHIEVENINGEN, a fishing town and watering-place of Holland, in the province of South Holland, on the German Ocean, 2 miles N.W. of the Hague. It contains a royal pavilion, Protestant and Roman Catholic churches, several schools and hospitals, and bathing establishments. Pop. 5600, chiefly employed in fishing.

SCHIEDAM, a seaport of Holland, in the province of South Holland, at the confluence of the Schie with the Meuse, 4 miles W. of Rotterdam. It has several regular, broad, and handsome streets, and not a few splendid buildings. The exchange is considered the finest of these; and there are also a town-hall, elegant concert-hall, and churches of various sects. Schiedam possesses numerous schools, a public library, benevolent institutions, &c. Its manufactures include hardware, glass, ropes, whitelead, linen, and flax. But it is best known for its distilleries of gin or Hollands, of which there are more than 200. There is a considerable trade in this, as well as in grain and coals. Many of the inhabitants are employed in the herring fishery. Pop. 12,500.

SCHILLER, **JOHN CHRISTOPHER FREDERICK VON**, was born at Marbach, a small town in the duchy of Würtemberg, on the 10th day of November 1759. It will aid the reader in synchronizing the periods of this great man's life with the corresponding events throughout Christendom, if we direct his attention to the fact, that Schiller's birth nearly coincided in point of time with that of Robert Burns, and that it preceded that of Napoleon by about ten years.

The position of Schiller is remarkable. In the land of his birth, by those who undervalue him the most, he is ranked as the second name in German literature; everywhere else he is ranked as the first. For us, who are aliens to Germany, Schiller is the representative of the German intellect in its highest form; and to him, at all events, whether first or second, it is certainly due, that the German intellect has become a known power, and a power of growing magnitude, for the great commonwealth of Christendom. Luther and Kepler, potent intellects as they were, did not make themselves known as Germans; the revolutionary vigour of the one, the starry lustre of the other, blended with the convulsions of reformation, or with the aurora of ascending science, in too kindly and genial a tone to call off the attention from the work which they performed, from the service which they promoted, to the circumstances of their personal position. Their country, their birth, their abode, even their separate existence, was merged in the mighty cause to which they lent their co-operation. And thus at the beginning of the sixteenth century, thus at the beginning of the seventeenth, did the Titan sons of Germany defeat their own private pretensions by the very grandeur of their merit. Their interest as patriots was lost and confounded in their paramount interest as cosmopolites. What

||
Schiller.

Schiller. they did for man and for human dignity eclipsed what they had designed for Germany. After them there was a long interlunar period of darkness for the land of the Rhine and the Danube. The German energy, too spasmodically excited, suffered a collapse. Throughout the whole of the seventeenth century, but one vigorous mind arose for permanent effects in literature. This was Opitz, a poet who deserves even yet to be read with attention, but who is no more worthy to be classed as the Dryden whom his too partial countrymen have styled him, than the Germany of the Thirty Years' War of taking rank by the side of civilized and cultured England during the Cromwellian era, or Klopstock of sitting on the same throne with Milton. Leibnitz was the one sole potentate in the fields of intellect whom the Germany of this century produced; and he, like Luther and Kepler, impresses us rather as a European than as a German mind, partly perhaps from his having pursued his self-development in foreign lands, partly from his large circle of foreign connections, but most of all from his having written chiefly in French or in Latin. Passing onwards to the eighteenth century, we find, through its earlier half, an absolute wilderness, unreclaimed and without promise of natural vegetation, as the barren arena on which the few insipid writers of Germany paraded. The torpor of academic dullness domineered over the length and breadth of the land. And as these academic bodies were universally found harnessed in the equipage of petty courts, it followed that the lethargies of pedantic dullness were uniformly deepened by the lethargies of aulic and ceremonial dullness; so that, if the reader represents to himself the very abstract of birthday odes, sycophantish dedications, and court sermons, he will have some adequate idea of the sterility and the mechanical formality which at that era spread the sleep of death over German literature. Literature, the very word literature, points the laughter of scorn to what passed under that name during the period of Gottsched. That such a man indeed as this Gottsched, equal at the best to the composition of a Latin grammar or a school arithmetic, should for a moment have presided over the German muses, stands out as in itself a brief and significant memorial, too certain for contradiction, and yet almost too gross for belief, of the apoplectic sleep under which the mind of central Europe at that era lay oppressed. The rust of disuse had corroded the very principles of activity. And, as if the double night of academic dullness, combined with the dullness of court inanities, had not been sufficient for the stifling of all native energies, the feebleness of French models (and of these moreover naturalized through still feeblier imitations) had become the law and standard for all attempts at original composition. The darkness of night, it is usually said, grows deeper as it approaches the dawn; and the very enormity of that prostration under which the German intellect at this time groaned, was the most certain pledge to any observing eye of that intense re-action soon to stir and kindle among the smouldering activities of this spell-bound people. This re-action, however, was not abrupt and theatrical: it moved through slow stages and by equable gradations: it might be said to commence from the middle of the eighteenth century, that is, about nine years before the birth of Schiller; but a progress of forty years had not carried it so far towards its meridian altitude, as that the sympathetic shock from the French Revolution was by one fraction more rude and shattering than the public torpor still demanded. There is a memorable correspondency throughout all members of Protestant Christendom in whatsoever relates to literature and intellectual advance. However imperfect the organization which binds them together, it was sufficient even in these elder times to transmit reciprocally from one to every other, so much of that illumination which could be gathered into books, that no Christian state could be much in advance of another, supposing that Popery op-

posed no barriers to free communication, unless only in those points which depended upon local gifts of nature, upon the genius of a particular people, or upon the excellence of its institutions. These advantages were incommunicable, let the freedom of intercourse have been what it might: England could not send off by posts or by heralds her iron and coals; she could not send the indomitable energy of her population; she could not send the absolute security of property; she could not send the good faith of her parliaments. These were gifts indigenous to herself, either through the temperament of her people, or through the original endowments of her soil. But her condition of moral sentiment, her high-toned civic elevation, her atmosphere of political feeling and popular boldness,—much of these she could and did transmit, by the radiation of the press, to the very extremities of the German empire. Not only were our books translated, but it is notorious to those acquainted with German novels, or other pictures of German society, that as early as the Seven Years' War (1756–1763), in fact, from the very era when Cave and Dr Johnson first made the parliamentary debates accessible to the English themselves, most of the German journals repeated, and sent forward as by telegraph, these senatorial displays to every village throughout Germany. From the polar latitudes to the Mediterranean, from the mouths of the Rhine to the Euxine, there was no other exhibition of free deliberative eloquence in any popular assembly. And the *Luse* of Voss alone, a metrical idyll not less valued for its truth of portraiture than our own Vicar of Wakefield, will show, that the most sequestered clergyman of a rural parish did not think his breakfast equipage complete without the latest report from the great senate that sat in London. Hence we need not be astonished that German and English literature were found by the French Revolution in pretty nearly the same condition of semi-vigilance and imperfect animation. That mighty event reached us both, reached us all, we may say (speaking of Protestant states), at the same moment, by the same tremendous galvanism. The snake, the intellectual snake, that lay in ambush among all nations, roused itself, sloughed itself, renewed its youth, in all of them at the same period. A new world opened upon us all; new revolutions of thought arose; new and nobler activities were born; “and other palms were won.”

But by and through Schiller it was, as its main organ, that this great revolutionary impulse expressed itself. Already, as we have said, not less than forty years before the earthquake by which France exploded and projected the scoria of her huge crater over all Christian lands, a stirring had commenced among the dry bones of intellectual Germany; and symptoms arose that the breath of life would soon disturb, by nobler agitations than by petty personal quarrels, the death-like repose even of the German universities. Precisely in those bodies however it was, in those as connected with tyrannical governments, each academic body being shackled to its own petty centre of local despotism, that the old spells remained unlinked; and to them, equally remarkable as firm trustees of truth, and as obstinate depositories of darkness or of superannuated prejudice, we must ascribe the slowness of the German movement on the path of reascend. Meantime the earliest torch-bearer to the murky literature of this great land, this crystallisation of political states, was Bodmer. This man had no demoniac genius, such as the service required; but he had some taste, and, what was better, he had some sensibility. He lived among the Alps; and his reading lay among the alpine sublimities of Milton and Shakspeare. Through his very eyes he imbibed a daily scorn of Gottsched and his monstrous compound of German coarseness with French sensual levity. He could not look at his native Alps, but he saw in them, and their austere grandeurs or their dread realities, a spiritual reproach to the hollowness and falsehood

Schiller.

Schiller.

of that dull imposture which Gottsched offered by way of substitute for nature. He was taught by the Alps to crave for something nobler and deeper. Bodmer, though far below such a function, rose by favour of circumstances into an apostle or missionary of truth for Germany. He translated passages of English literature. He inoculated with his own sympathies the more fervent mind of the youthful Klopstock, who visited him in Switzerland. And it soon became evident that Germany was not dead, but sleeping; and once again, legibly for any eye, the pulses of life began to play freely through the vast organization of central Europe.

Klopstock, however, though a fervid, a religious, and for that reason an anti-Gallican mind, was himself an abortion. Such at least is our own opinion of this poet. He was the child and creature of enthusiasm, but of enthusiasm not allied with a masculine intellect, or any organ for that capacious vision and meditative range which his subjects demanded. He was essentially thoughtless, betrays everywhere a most effeminate quality of sensibility, and is the sport of that pseudo-enthusiasm and baseless rapture which we see so often allied with the excitement of strong liquors. In taste, or the sense of proportions and congruences, or the harmonious adaptations, he is perhaps the most defective writer extant.

But if no patriarch of German literature, in the sense of having shaped the moulds in which it was to flow, in the sense of having disciplined its taste or excited its rivalry by classical models of excellence, or raised a finished standard of style, perhaps we must concede that, on a minor scale, Klopstock did something of that service in every one of these departments. His works were at least Miltonic in their choice of subjects, if ludicrously non-Miltonic in their treatment of those subjects. And, whether due to him or not, it is undeniable that in his time the mother-tongue of Germany revived from the most absolute degradation on record, to its ancient purity. In the time of Gottsched, the authors of Germany wrote a macaronic jargon, in which French and Latin made up a considerable proportion of every sentence: nay, it happened often that foreign words were inflected with German forms; and the whole result was such as to remind the reader of the medical examination in the *Malade Imaginaire* of Molière,

Quid poetæ est à faire ?

Saignare

Baignare

Ensuita purgare, &c.

Now is it reasonable to ascribe some share in the restoration of good to Klopstock, both because his own writings exhibit nothing of this most abject euphuism (a euphuism expressing itself not in fantastic refinements on the staple of the language, but altogether in rejecting it for foreign words and idioms), and because he wrote expressly on the subject of style and composition.

Wieland, meantime, if not enjoying so intense an acceptance as Klopstock, had a more extensive one; and it is in vain to deny him the praise of a festive, brilliant, and most versatile wit. The Schlegels showed the haughty malignity of their ungenerous natures, in depreciating Wieland, at a time when old age had laid a freezing hand upon the energy which he would once have put forth in defending himself. He was the Voltaire of Germany, and very much more than the Voltaire; for his romantic and legendary poems are above the level of Voltaire. But, on the other hand, he was a Voltaire in sensual impurity. To work, to carry on a plot, to affect his readers by voluptuous impressions,—these were the unworthy aims of Wieland; and though a good natured critic would not refuse to make some

Schiller.

allowance for a youthful poet's aberrations in this respect, yet the indulgence cannot extend itself to mature years. An old man corrupting his readers, attempting to corrupt them, or relying for his effect upon corruptions already effected, in the purity of their affections, is a hideous object; and that must be a precarious influence indeed which depends for its durability upon the licentiousness of men. Wieland, therefore, except in parts, will not last as a national idol; but such he was nevertheless for a time.

Bürger wrote too little of any expansive compass to give the measure of his powers, or to found national impression; Lichtenberg, though a very sagacious observer, never rose into what can be called a *power*—he did not modify his age; yet these were both men of extraordinary talent, and Bürger a man of undoubted genius. On the other hand, Lessing was merely a man of talent, but of talent in the highest degree adapted to popularity. His very defects, and the shallowness of his philosophy, promoted his popularity; and by comparison with the French critics on the dramatic or scenical proprieties he is ever profound. His plummet, if not suited to the soundless depths of Shakspeare, was able ten times over to fathom the little rivulets of Parisian philosophy. This he did effectually, and thus unconsciously levelled the paths for Shakspeare, and for that supreme dominion which he has since held over the German stage, by crushing with his sarcastic shrewdness the pretensions of all who stood in the way. At that time, and even yet, the functions of a literary man were very important in Germany: the popular mind and the popular instinct pointed one way, those of the little courts another. Multitudes of little German states (many of which were absorbed since 1816 by the process of *mediatizing*) made it their ambition to play at keeping mimic armies in their pay, and to ape the greater military sovereigns, by encouraging French literature only, and the French language at their courts. It was this latter propensity which had generated the anomalous macaronic dialect, of which we have already spoken as a characteristic circumstance in the social features of literary Germany during the first half of the eighteenth century. Nowhere else, within the records of human follies, do we find a corresponding case in which the government and the patrician orders in the state, taking for granted, and absolutely postulating the utter worthlessness for intellectual aims of those in and by whom they maintained their own grandeur and independence, undisguisedly and even professedly sought to ally themselves with a foreign literature, foreign literati, and a foreign language. In this unexampled display of scorn for native resources, and the consequent collision between the two principles of action, all depended upon the people themselves. For a time the wicked and most profligate contempt of the local governments for that native merit which it was their duty to evoke and to cherish, naturally enough produced its own justification. Like Jews or slaves, whom all the world have agreed to hold contemptible, the German literati found it hard to make head against so obstinate a prejudice; and too often they became all that they were presumed to be. *Sint Mæcenates, non deerunt, Flacce, Marones*. And the converse too often holds good—that when all who should have smiled scowl upon a man, he turns out the abject thing they have predicted. Where Frenchified Fredericks sit upon German thrones, it should not surprise us to see a crop of Gottscheds arise as the best fruitage of the land. But when there is any latent nobility in the popular mind, such scorn, by its very extremity, will call forth its own counteraction. It was perhaps good for Germany that a prince so eminent in one aspect as *Fritz der einziger*,¹ should put on record so emphatically his intense conviction, that no good thing could arise out of Ger-

¹ "*Freddy the unique*," which is the name by which the Prussians expressed their admiration of their martial and indomitable, though somewhat fantastic, king.

Schiller. many. This creed was expressed by the quality of the French minds which he attracted to his court. The very refuse and dregs of the Parisian coteries satisfied his hunger for French garbage; the very offal of their shambles met the demand of his palate; even a Maupertuis, so long as he could produce a French baptismal certificate, was good enough to manufacture into the president of a Berlin academy. Such scorn challenged a re-action: the contest lay between the thrones of Germany and the popular intellect, and the final result was inevitable. Once aware that they were insulted, once enlightened to the full consciousness of the scorn which trampled on them as intellectual and predestined Helots, even the mild-tempered Germans became fierce, and now began to aspire, not merely under the ordinary instincts of personal ambition, but with a vindictive feeling, and as conscious agents of retribution. It became a pleasure with the German author, that the very same works which elevated himself, wreaked his nation upon their princes, and poured retorted scorn upon their most ungenerous and unparental sovereigns. Already, in the reign of the martial Frederick, the men who put most weight of authority into his contempt of Germans,—Euler, the matchless Euler, Lambert, and Immanuel Kant,—had vindicated the pre-eminence of German mathematics. Already, in 1755, had the same Immanuel Kant, whilst yet a probationer for the chair of logic in a Prussian university, sketched the outline of that philosophy which has secured the admiration, though not the assent, of all men known and proved to have understood it, of all men able to state its doctrines in terms admissible by its disciples. Already, and even previously, had Haller, who wrote in German, placed himself at the head of the current physiology. And in the fields of science or of philosophy, the victory was already decided for the German intellect in competition with the French.

But the fields of literature were still comparatively barren. Klopstock was at least an anomaly; Lessing did not present himself in the impassioned walks of literature; Herder was viewed too much in the exclusive and professional light of a clergyman; and, with the exception of John Paul Richter, a man of most original genius, but quite unfitted for general popularity, no commanding mind arose in Germany with powers for levying homage from foreign nations, until the appearance, as a great scenical poet, of Frederick Schiller.

The father of this great poet was Caspar Schiller, an officer in the military service of the Duke of Würtemberg. He had previously served as a surgeon in the Bavarian army; but on his final return to his native country of Würtemberg, and to the service of his native prince, he laid aside his medical character for ever, and obtained a commission as ensign and adjutant. In 1763, the peace of Paris threw him out of his military employment, with the nominal rank of captain. But, having conciliated the duke's favour, he was still borne on the books of the ducal establishment; and, as a planner of ornamental gardens, or in some other civil capacity, he continued to serve his serene highness for the rest of his life.

The parents of Schiller were both pious, upright persons, with that loyal fidelity to duty, and that humble simplicity of demeanour towards their superiors, which is so often found among the unpretending natives of Germany. It is probable, however, that Schiller owed to his mother exclusively the preternatural endowments of his intellect. She was of humble origin, the daughter of a baker, and not so fortunate as to have received much education. But she was apparently rich in gifts of the heart and the understanding. She read poetry with delight; and through the profound filial love with which she had inspired her son, she found it easy to communicate her own literary tastes. Her husband was not illiterate, and had in mature life so

laudably applied himself to the improvement of his own defective knowledge, that at length he thought himself capable of appearing before the public as an author. His book related simply to the subjects of his professional experience as a horticulturist, and was entitled *Die Baumzucht im Grossen* (On the Management of Forests). Some merit we must suppose it to have had, since the public called for a second edition of it long after his own death, and even after that of his illustrious son. And although he was a plain man, of no pretensions, and possibly even of slow faculties, he has left behind him a prayer, in which there is one petition of sublime and pathetic piety, worthy to be remembered by the side of Agar's wise prayer against the almost equal temptations of poverty and riches. At the birth of his son, he had been reflecting with sorrowful anxiety, not unmingled with self-reproach, on his own many disqualifications for conducting the education of the child. But at length, reading in his own manifold imperfections but so many reiterations of the necessity that he should rely upon God's bounty, converting his very defects into so many arguments of hope and confidence in heaven, he prayed thus: "Oh God, that knowest my poverty in good gifts for my son's inheritance, graciously permit that, even as the want of bread became to thy Son's hunger-stricken flock in the wilderness the pledge of overflowing abundance, so likewise my darkness may, in its sad extremity, carry with it the measure of thy unfathomable light; and because I, thy worm, cannot give to my son the least of blessings, do thou give the greatest; because in my hands there is not any thing, do thou from thine pour out all things; and that temple of a new-born spirit, which I cannot adorn even with earthly ornaments of dust and ashes, do thou irradiate with the celestial adornment of thy presence, and finally with that peace that passeth all understanding."

Reared at the feet of parents so pious and affectionate, Schiller would doubtless pass a happy childhood; and probably to this utter tranquillity of his earlier years, to his seclusion from all that could create pain, or even anxiety, we must ascribe the unusual dearth of anecdotes from this period of his life; a dearth which has tempted some of his biographers into improving and embellishing some puerile stories, which a man of sense will inevitably reject as too trivial for his gravity or too fantastical for his faith. That nation is happy, according to a common adage, which furnishes little business to the historian; for such a vacuity in facts argues a condition of perfect peace and silent prosperity. That childhood is happy, or may generally be presumed such, which has furnished few records of external experience, little that has appeared in doing or in suffering to the eyes of companions; for the child who has been made happy by early thoughtfulness, and by infantine struggles with the great ideas of his origin and his destination (ideas which settle with a deep, dove-like brooding upon the mind of childhood, more than of mature life, vexed with inroads from the noisy world), will not manifest the workings of his spirit by much of external activity. The *fallentis semita vitæ*, that path of noiseless life, which eludes and deceives the conscious notice both of its subject and of all around him, opens equally to the man and to the child; and the happiest of all childhoods will have been that of which the happiness has survived and expressed itself, not in distinct records, but in deep affection, in abiding love, and the hauntings of meditative power.

Such a childhood, in the bosom of maternal tenderness, was probably passed by Schiller; and his first awaking to the world of strife and perplexity happened in his fourteenth year. Up to that period his life had been vagrant, agreeably to the shifting necessities of the ducal service; and his education desultory and domestic. But in the year 1773 he was solemnly entered as a member of a new aca-

Schiller. demical institution, founded by the reigning duke, and recently translated to his little capital of Stuttgart. This change took place at the special request of the duke, who, under the mask of patronage, took upon himself the severe control of the whole simple family. The parents were probably both too humble and dutiful in spirit towards one whom they regarded in the double light of sovereign lord and of personal benefactor, ever to murmur at the ducal behests, far less to resist them. The duke was for them an earthly providence; and they resigned themselves, together with their child, to the disposal of him who dispensed their earthly blessings, not less meekly than of Him whose vicergerent they presumed him to be. In such a frame of mind, requests are but another name for commands; and thus it happened that a second change arose upon the first, even more determinately fatal to the young Schiller's happiness. Hitherto he had cherished a day-dream pointing to the pastoral office in some rural district, as that which would harmonize best with his intellectual purposes, with his love of quiet, and, by means of its preparatory requirements, best also with his own peculiar choice of studies. But this scheme he now found himself compelled to sacrifice; and the two evils which fell upon him concurrently in his new situation were, first, the formal military discipline and monotonous routine of duty; secondly, the uncongenial direction of the studies, which were shaped entirely to the attainment of legal knowledge, and the narrow service of the local tribunals. So illiberal and so exclusive a system of education was revolting to the expansive mind of Schiller; and the military bondage under which this system was enforced, shocked the aspiring nobility of his moral nature, not less than the technical narrowness of the studies shocked his understanding. In point of expense the whole establishment cost nothing at all to those parents who were privileged servants of the duke: in this number were the parents of Schiller, and that single consideration weighed too powerfully upon his filial piety to allow of his openly murmuring at his lot; while on *their* part the parents were equally shy of encouraging a disgust which too obviously tended to defeat the promises of ducal favour. This system of monotonous confinement was therefore carried to its completion, and the murmurs of the young Schiller were either dutifully suppressed, or found vent only in secret letters to a friend. In one point only Schiller was able to improve his condition; jointly with the juristic department, was another for training young aspirants to the medical profession. To this, as promising a more enlarged scheme of study, Schiller by permission transferred himself in 1775. But whatever relief he might find in the nature of his new studies, he found none at all in the system of personal discipline which prevailed.

Under the oppression of this detested system, and by pure re-action against its wearing persecutions, we learn from Schiller himself, that in his nineteenth year he undertook the earliest of his surviving plays, the *Robbers*, beyond doubt the most tempestuous, the most volcanic, we might say, of all juvenile creations anywhere recorded. He himself calls it "a monster," and a monster it is; but a monster which has never failed to convulse the heart of young readers with the temperament of intellectual enthusiasm and sensibility. True it is, and nobody was more aware of that fact than Schiller himself in after years, the characters of the three Moors, father and sons, are mere impossibilities; and some readers, in whom the judicious acquaintance with human life in its realities has outrun the sensibilities, are so much shocked by these hypernatural phenomena, that they are incapable of enjoying the terrific sublimities which on that basis of the visionary do really exist. A poet, perhaps Schiller might have alleged, is entitled to assume hypothetically so much in the previous positions or circumstances of his agents as is requisite to the

basis from which he starts. It is undeniable that Shakspeare and others have availed themselves of this principle, and with memorable success. Shakspeare, for instance, *postulates* his witches, his Caliban, his Ariel: grant, he virtually says, such modes of spiritual existence or of spiritual relations as a possibility; do not expect me to demonstrate this, and upon that single concession I will rear a superstructure that shall be self-consistent; every thing shall be *internally* coherent and reconciled, whatever be its *external* relations as to our human experience. But this species of assumption, on the largest scale, is more within the limits of credibility and plausible versimilitude when applied to modes of existence, which, after all, are in such total darkness to us (the limits of the possible being so undefined and shadowy as to what can or cannot exist), than the very slightest liberties taken with human character, or with those principles of action, motives, and feelings, upon which men would move under given circumstances, or with the modes of action which in common prudence they would be likely to adopt. The truth is, that, as a coherent work of art, the *Robbers* is indefensible; but, however monstrous it may be pronounced, it possesses a power to agitate and convulse, which will always obliterate its great faults to the young, and to all whose judgment is not too much developed. And the best apology for Schiller is found in his own words in recording the circumstances and causes under which this anomalous production arose. "To escape," says he, "from the formalities of a discipline which was odious to my heart, I sought a retreat in the world of ideas and shadowy possibilities, while as yet I knew nothing at all of that human world from which I was harshly secluded by iron bars. Of men, the actual men in this world below, I knew absolutely nothing at the time when I composed my *Robbers*. Four hundred human beings, it is true, were my fellow-prisoners in this abode; but they were mere tautologies and reiterations of the self-same mechanic creature, and like so many plaster casts from the same original statue. Thus situated, of necessity I failed. In making the attempt, my chisel brought out a monster, of which [and that was fortunate] the world had no type or resemblance to show."

Meantime this demoniac drama produced very opposite results to Schiller's reputation. Among the young men of Germany it was received with an enthusiasm absolutely unparalleled, though it is perfectly untrue that it excited some persons of rank and splendid expectations (as a current fable asserted) to imitate Charles Moor in becoming robbers. On the other hand, the play was of too powerful a cast not in any case to have alarmed his serenity the Duke of Wurtemberg; for it argued a most revolutionary mind, and the utmost audacity of self-will. But besides this general ground of censure, there arose a special one, in a quarter so remote that this one fact may serve to evidence the extent as well as intensity of the impression made. The territory of the Grisons had been called by Spiegelberg, one of the robbers, "the Thief's Athens." Upon this the magistrates of that country presented a complaint to the duke; and his highness, having cited Schiller to his presence, and severely reprimanded him, issued a decree that this dangerous young student should henceforth confine himself to his medical studies.

The persecution which followed exhibits such extraordinary exertions of despotism, even for that land of irresponsible power, that we must presume the duke to have relied more upon the hold which he had upon Schiller through his affection for parents so absolutely dependent on his highness's power, than upon any laws, good or bad, which he could have pleaded as his warrant. Germany, however, thought otherwise of the new tragedy than the serene critic of Wurtemberg: it was performed with vast applause at the neighbouring city of Mannheim; and thither, under

Schiller.

Schiller. a most excusable interest in his own play, the young poet clandestinely went. On his return he was placed under arrest. And soon afterwards, being now thoroughly disgusted, and, with some reason, alarmed by the tyranny of the duke, Schiller finally eloped to Mannheim, availing himself of the confusion created in Stuttgart by the visit of a foreign prince.

At Mannheim he lived in the house of Dalberg, a man of some rank and of sounding titles, but in Mannheim known chiefly as the literary manager (or what is called director) of the theatre. This connection aided in determining the subsequent direction of Schiller's talents; and his *Fiesco*, his *Intrigue and Love*, his *Don Carlos*, and his *Maria Stuart*, followed within a short period of years. None of these are so far free from the faults of the Robbers as to merit a separate notice; for with less power, they are almost equally licentious. Finally, however, he brought out his *Wallenstein*, an immortal drama, and, beyond all competition, the nearest in point of excellence to the dramas of Shakspeare. The position of the characters of Max. Piccolomini and the Princess Thekla is the finest instance of what, in a critical sense, is called *relief*; that literature offers. Young, innocent, unfortunate, among a camp of ambitious, guilty, and blood-stained men, they offer a depth and solemnity of impression which is equally required by way of contrast and of final repose.

From Mannheim, where he had a transient love affair with Laura Dalberg, the daughter of his friend the director, Schiller removed to Jena, the celebrated university in the territory of Weimar. The grand duke of that German Florence was at this time gathering around him the most eminent of the German intellects; and he was eager to enrol Schiller in the body of his professors. In 1799 Schiller received the chair of civil history; and not long after he married Miss Lengefeld, with whom he had been for some time acquainted. In 1803 he was ennobled; that is, he was raised to the rank of gentleman, and entitled to attach the prefix of *Von* to his name. His income was now sufficient for domestic comfort and respectable independence; while in the society of Goethe, Herder, and other eminent wits, he found even more relaxation for his intellect, than his intellect, so fervent and so self-sustained, could require.

Meantime the health of Schiller was gradually undermined: his lungs had been long subject to attacks of disease; and the warning indications which constantly arose of some deep-seated organic injuries in his pulmonary system ought to have put him on his guard for some years before his death. Of all men, however, it is remarkable that Schiller was the most criminally negligent of his health; remarkable, we say, because for a period of four years Schiller had applied himself seriously to the study of medicine. The strong coffee, and the wine, which he drank, may not have been so injurious as his biographers suppose; but his habit of sitting up through the night, and defrauding his wasted frame of all natural and restorative sleep, had something in it of that guilt which belongs to suicide. On the 9th of May 1805 his complaint reached its crisis. Early in the morning he became delirious; at noon his delirium abated; and at four in the afternoon he fell into a gentle unagitated sleep, from which he soon awoke. Conscious that he now stood on the very edge of the grave, he calmly and fervently took a last farewell of his friends. At six in the evening he fell again into sleep, from which, however, he again awoke once more to utter the memorable declaration, "that many things were growing plain and clear to his understanding." After this the cloud of sleep again settled upon him; a sleep which soon changed into the cloud of death.

This event produced a profound impression throughout Germany. The theatres were closed at Weimar, and the funeral was conducted with public honours. The position in point of time, and the peculiar services of Schiller to the

German literature, we have already stated: it remains to add, that in person he was tall, and of a strong, bony structure, but not muscular, and strikingly lean. His forehead was lofty, his nose aquiline, and his mouth almost of Grecian beauty. With other good points about his face, and with auburn hair, it may be presumed that his whole appearance was pleasing and impressive, while in later years the character of sadness and contemplative sensibility deepened the impression of his countenance. We have said enough of his intellectual merit, which places him in our judgment at the head of the Trans-Rhenish literature. But we add in concluding, that Frederick von Schiller was something more than a great author; he was also in an eminent sense a great man; and his works are not more worthy of being studied for their singular force and originality, than his moral character from its nobility and aspiring grandeur. (T. DE Q.)

SCHINKEL, KARL FRIEDRICH, a very eminent German architect, was born on the 13th of March 1781, at Neuuppin, in Brandenburg. Having lost his father at an early age, he was placed by his mother at the gymnasium of his native town, where he remained till his fourteenth year, when he removed to Berlin. He soon found an entrance to the office of David Gilly, then an able practical architect; but he had hardly got fairly settled when his master died. Friedrich Gilly, his son, a youth of an ardent imagination, had just returned from his travels; and he began, full of hope and of ambition, to elevate architecture to the level of the other arts of design. His career was short, for he died in 1800, within two years after he had taken up his father's place. Schinkel was now left to pursue undivided the ambitious projects which the younger Gilly had designed, or if possible to realize higher architectural aims than either of his masters had entertained. Schinkel had already had considerable practical experience in the erection of buildings, and he now resolved to pursue his theoretical studies by a pilgrimage to Italy. Accordingly, in 1803, he set out, and after visiting Dresden, Prague, and Vienna, he entered the land sacred to art, and after spending a considerable time in minutely surveying all its architectural monuments, and noting down all its important architectural designs, he returned to Vienna in 1805, filled with the grandest imaginations which young wonder knows. The backward state of public affairs rendered his residence in Germany as an architect exceedingly problematical, and with a mind teeming with the richest art-knowledge, and aspiring after the richest field of development, he at once resolved to combine his architectural skill with his knowledge of landscape scenery, and to become a painter. Architecture, however, was still to hold the prominent part in his labours; the introduction of scenery was merely to act as an expression of his taste and imagination in the accessorial portion of his work. It was at this time he executed his admirable panorama of Palermo; and he likewise designed numerous scenes for the theatre, which were greatly esteemed. Meanwhile, these labours with his brush had brought him prominently before the public, and on the restoration of order in 1815, he was chosen by the king to adorn the city of Berlin and its environs. Those who know the beauties of that graceful city, and the artificial adornments of the surrounding neighbourhood, can testify to how well Schinkel performed his task, and to how great an amount of originality of conception and boldness of design he expended upon the embellishment of the capital of Prussia. Among his earliest buildings are the *Hauptwache*, the Theatre, and the Museum of Berlin, all treated in a purely Hellenic style, the latter of which displays a fulness of ornamentation, combined with a simple severity of outline, such as had not been witnessed before in Germany. A very fair idea of the range of Schinkel's art-knowledge may be

Schinznach gained from his *Entwürfe* (designs), which contain a complete gallery, with explanatory letterpress, of his unusually numerous and varied architectural productions. Besides presenting ready materials for a descriptive catalogue of his buildings, they likewise present a variety of six several designs for a monument to the great Friedrich, in which the artist had given the rein to his imagination, and indulged freely in the pomp of architectural circumstance and structural display. His *Werke der höheren Baukunst* exhibits a series of grand designs with which he proposed to adorn the acropolis of Athens, but the barrack-like fabric of Gurtner was preferred. Perhaps the most poetical of all Schinkel's designs was his plan of a summer palace for the Empress of Russia at Orianda, in the Crimea, overlooking the Black Sea. Besides being chosen professor in the Academy of Fine Arts at Berlin, and member of the Prussian Academical Senate, he had in 1839 the highest rank of his profession bestowed upon him. He was made "Oberlandesbaudirector," but he did not long enjoy the honour. He died of an organic affection of the brain on the 9th of October 1841. Dr Kugler and O. F. Gruppe have both written biographies of Schinkel.

SCHINZNACH, the most frequented watering-place in Switzerland, in the canton of Aargau, on the Aar, 7 miles N.E. of Aarau. It is well built, and has a fine church, but owes its importance entirely to the medicinal spring; and its chief buildings are the great inn and the bath-house, both very large and splendid. Pop. 1334.

SCHIO, a town of Austrian Italy, in the delegation and 15 miles N.W. of Vicenza. It stands in a fertile plain, between the rivers Leogra and Timonchio, and contains churches, hospitals, law courts, and public offices. There are here mineral springs, and several manufactures are carried on, especially those of woollen cloth, silk, and dyeing. Pop. 6620.

SCHISM (σχίσμα, a rent), in its general acceptation signifies division or separation; but it is chiefly used in speaking of separations happening from diversity of opinions among people of the same religion or faith. Thus we say the schism of the ten tribes of Judah and Benjamin, the schism of the Persians from the Turks and other Mahomedans, &c. Among ecclesiastical authors, the great schism of the west is that which happened in the times of Clement VII. and Urban VI., which divided the church for forty or fifty years, and was at length ended by the election of Martin V. at the council of Constance. The Romanists number thirty-four schisms in their church, and bestow the name of English schism on the reformation of religion in this kingdom. Those of the church of England apply the term schism to the separation of the nonconformists, viz., the Presbyterians, Independents, and Baptists, for a further reformation.

SCHLAN, or SLANY, a town of the Austrian Empire, Bohemia, in the circle and 20 miles N.W. of Prague. It is walled, and contains a town-hall, Franciscan convent, Piarist college, and high school. There are in the town manufactures of cloth and beet-root sugar; and in the vicinity, salt-springs and coal-pits. Pop. 4531.

SCHLAWE, a town of Prussia, province of Pomerania, in the circle and 23 E.N.E. of Cöslin, at the confluence of the Wipper and the Motze. Linen weaving is carried on here, and some trade in linen and timber. Pop. 4382.

SCHLEGEL, AUGUST WILHELM VON, the elder brother of Friedrich Carl Wilhelm Von Schlegel, and an eminent philologist and critic of Germany, was the son of Johann Adolphus Schlegel, and was born at Hanover in the month of September 1767. He betrayed early a natural gift for language, which carried him through the grammar school of Hanover with great reputation. On leaving school he accepted of a tutorial appointment which demanded of the holder a knowledge both of the French and English lan-

guages. He was chosen in his eighteenth year to deliver an oration before the Lyceum of his native city in honour of a royal birthday. This address, which was written in German hexameters, excited considerable sensation in the citizens of Hanover, both from the range of information displayed in it and from the elegant style in which it was composed. Proceeding to the University of Göttingen, he engaged in the study of theology, but which he shortly afterwards abandoned for the more congenial one of philology. He had already made great progress in classical learning, and his Latin Dissertation on the geography of Homer was warmly applauded by Voss, the most competent judge of his age. While at the university he made the acquaintance of Heyne, for whose Virgil he completed an index in 1788. He likewise gained the friendship of the distinguished Michaelis, and of the poet Bürger, to whose *Academie der Schönen Redekunste* he contributed his *Ariadne* and his Essay on Dante. Having from his early youth had a leaning to poetry, he now, in conjunction with Bürger, made considerable advances in that species of composition, and had the honour of naturalizing the Italian sonnet in his native country. On leaving the university he became tutor to the son of a wealthy banker of Amsterdam, and after a three years' engagement, he again sought retirement in the University of Jena, where he was appointed professor. He now contributed largely to the *Horen*, and to Schiller's *Musen-Almanach*; and down to 1779 he was one of the most elegant and fertile writers for the *Allgemeinen Literatur-Zeitung* of Jena. It was here he began to disclose to his countrymen the enchanted world of Shakspeare (9 vols., Berlin, 1797-1810), which produced a decided change in the dramatic criticism of Germany. He subsequently renounced in favour of Tieck the work of rendering Shakspeare into German, a change with which the public were not at all dissatisfied, as the exceeding elegance, amounting sometimes to starchedness, of Schlegel's manner, did not always suit the free and unfettered genius of the English poet. During his residence in Jena he became acquainted with Schiller, and professed admiration for Goethe, who, however, did not return the compliment. Schlegel now commenced a course of lectures on æsthetics, and joined his brother, Frederick, in the editorship of the *Athenæum* (3 vols., Berlin, 1796-1800), a journal of literary criticism, designed by its freedom and impartiality to discover and foster every spark of genuine literary development in Germany. In 1800 he published his exceedingly ill-natured satire on Kotzebue, in reply to his attack of the *Hyperborean Ass* (*Hyperboreischen Esee*). About this period appeared his *Gedichte* (poems), Tübingen, 1800, which were much admired for their elegance and spirit.

He collected his own and his brother Friedrich's contributions to various periodicals, and brought them out under the title of *Characteristiken und Kritiken*, 2 vols., Königsberg, 1801. He undertook with Tieck the editorship of the *Musen-Almanach* for 1802; and with minds of a kindred temper continued to promulgate the doctrines of the so-called romanticists. Fired by ambition, and perhaps also by vanity, August Schlegel now left Jena for Berlin, where he found the most intellectual public of Germany ready to listen to his lectures. He was accordingly induced to deliver a course in 1802, which subsequently appeared in the *Europa*, a review edited by his brother. They bore the title of *Vorlesungen über Literatur und Kunst des Zeitalters* (Lectures on the Literature and Fine Arts of the Age). His *Ion*, a drama in imitation of the ancients, published in 1803, and not marked by any peculiar vigour either of conception or of execution, led to an interesting discussion between the author and some literary men of the day regarding dramatic representation in general, and which was carried on in the *Zeitung für die elegante Welt*. It was from this journal, also, that A. Schlegel shot

Schlegel.

Schlegel. forth his darts against Kotzebue and the classicists, who constantly infested him, with all manner of weapons, from the lightest arrowy banter to the deadliest personal abuse. And in giving them back their blows, the galled romanticist did not bate a jot either in keenness of weapon or force of stroke. Schlegel was now engaged upon his Spanish Theatre, which he gave to the world in 2 vols. at Berlin, 1803-1809. In this version he observed all the measures, rythms, and assonances of the original, and earned for himself a foremost place among successful translators. The German public had another proof of his skill in his *Blumenstrausse d. Ital. Span. u. Portug. Poesie*, Berlin, 1804.

An important career now presented itself to August Schlegel by his introduction to the celebrated Madame de Staël. That lady had arrived in Berlin in 1805, with the intention of making a tour through Germany and of making herself more thoroughly acquainted with German literature. She chose A. Schlegel to direct her studies and to complete the education of her children. Quitting Berlin, he accompanied her to Italy, France, Austria, and Sweden, and subsequently repaired with her to her paternal seat at Coppet, on the Lake of Geneva. It was here he wrote, in 1807, his *Comparaison de la Phèdre d'Euripide, et de celle de Racine*, which produced a lively sensation in the salons of Paris. He is said to have had many friends and admirers in the French capital, despite his attack upon Racine, and his having called Molière a mountebank. In the spring of 1808 he visited Vienna, and there read before a brilliant audience his *Vorlesungen über Dramatische Kunst und Literatur*, 3 vols., Heidelberg, 1809-11, which were received throughout Europe with marked approbation. These lectures on dramatic art and literature are, with all their defects, unquestionably his most popular work. They were rendered into English by John Black, 3 vols., 8vo, London, 1840, reprinted in Bohn's "Standard Library," 1 vol. 1846. He was introduced about this time to the Crown Prince of Bavaria, who gratified the vanity of August Wilhelm Schlegel by bestowing upon him some marks of the royal favour. A new edition of his *Gedichte* appeared in 1811, among which are his "Arion," "Pygmalion," "Der Heilige Lucas," &c., which are said to be the best of his poetical efforts. He likewise took part in the *Deutsche Museum*, a publication issued by his brother Friedrich, and contributed to it some learned dissertations on the *Nibelungen Lied*. In 1812 he visited Stockholm together with De Staël, where he duly made the acquaintance of Bernadotte, Crown Prince of Sweden, who made him his secretary and counsellor. He continued to write political papers for Bernadotte till the taking of Paris, when he retired to the country-seat of Madame de Staël, with whom he remained till her death in 1818. He was ennobled about this time by the Crown Prince of Sweden, as an expression of his esteem for him during his residence in Stockholm. On the creation, in 1819, of the university of Bonn, August Von Schlegel was chosen professor of history, for what particular reason does not appear. He had never written anything historical, and if one may judge of his fitness for such a position from his ridiculous critique of Niebuhr's *Roman History* in 1828, one would be inclined to say he should have remained at Berlin or Vienna, where he could have had abundant means of enlightening the fair intellects of the elegant beauties which frequent those courtly cities. He added nothing to his reputation by his Bonn professorship. He married this year a daughter of Professor Paulus, a union which was destined to be as short-lived as had been his previous one with the daughter of Michaelis. He now resolved to devote himself exclusively to the study of Sanscrit. With this view he established the printing-office at Bonn for the publication of that language. In 1820 he founded the *Indische Bibliothek* (2 vols., Bonn, 1820-26),

a review devoted exclusively to Indian languages and antiquities. Inferior to Bopp and Lassen as a Sanscrit scholar, he surpassed them in his general views, and contributed very considerably to the diffusion of a taste for the Indo-Persian languages. Indeed, it is mainly owing to his exertions in this department, and to his critical essays on æsthetics and poetry, that August Von Schlegel stands so high as he does in the esteem of his country. He published the *Ramâyana*, Bonn, 1825; and the *Bagavad-Gita*, an episode in the great Indian epos, *Mahabharata*, Bonn, 1829, which afford favourable specimens of his Sanscrit learning. He likewise visited France and England in pursuit of oriental manuscripts. On his return to Berlin he delivered a course of *Vorlesungen über Theorie und Geschichte der bildenden Kunst*, Berlin, 1827; and the following year he published his *Kritische Schriften*, Berlin, 1828. This same year he published an *Explication de quelques Mal-entendus*, in reply to an accusation which had been repeatedly preferred against him, of having a leaning towards Roman Catholicism. In 1832, he addressed to Sir James Mackintosh his *Reflexions sur l'Etude des Langues Asiatique*. After publishing, in 1842, his *Essais Littéraires et Historiques*, and after spending a long career of successful literary labour, August Von Schlegel died at Bonn on the 12th of May 1845. His printed works amounted to one hundred and twenty-six in all, and he bequeathed his unpublished manuscripts to Professor Welcker of Bonn, with a view to their publication.

August Schlegel, although possessed of a more lively imagination and greater powers of illustration than his brother Friedrich, was wanting in those solid critical faculties which gained for him his fame. He was a man of immoderate vanity, and possibly this natural defect may have qualified in an important manner the development of his critical faculties. With more brilliant talents than his brother, he earned for himself a less enduring reputation.

SCHLEGEL, *Friedrich Carl Wilhelm von*, an eminent German critic and philosophical writer, was born at Hanover in 1772, of a family which had already produced more than one writer of ability. He was the third son of the family, being three years younger than his distinguished brother, August Wilhelm. In his earlier years he is said to have displayed no remarkable genius. Though intended for the mercantile profession, he received an admirable classical education; and ultimately prevailed on his father to allow him to follow the bent of his own inclination, and to devote himself to literature. He then began to devote himself in earnest to study, which he pursued, first at Gottingen and afterwards at Leipzig. From the age of seventeen, as he himself informs us, the writings of the Greek tragedians, and of Plato, combined with Winkelmann's enthusiastic criticisms on art, formed the intellectual world in which he lived. This admiration for the antique was increased by a visit which he was enabled to pay to Dresden in 1789, where he was for the first time enabled to contemplate, in their marble forms, those gods, heroes, and sages, who had been the companions of his thoughts. As might be expected, his first literary effort, which appeared in 1794, took the direction of these his early studies. It was a short Essay on the different Schools of Greek Poetry, which appeared in the *Berlin Monatsschrift*, displaying not only an erudition of considerable depth and extent, but an elegance of style and a clearness of classification less frequently to be found among his countrymen. Two little treatises followed, composed in 1795 and 1796—the *Diotema*, a view of the condition of the female sex in Greece; and a parallel between Cæsar and Alexander, which, however, was not published till twenty-six years afterwards. In this work we trace the first indications of that talent which was afterwards so conspicuously displayed in the field of philosophical and criti-

Schlegel.

Schlegel

cal history. A more important work, entitled the *Griechen und Römer*, appeared in 1797, which was highly praised by Heine. It was followed two or three years afterwards by a *History of Greek Poetry*, in which, taking Winkelmann's *History of Art* as his model, he has thrown into criticism an imaginative and poetical tone, which combining as it did with profound learning and breadth of philosophical views, succeeded in bringing before the mind the true spirit of antiquity, with a freshness and distinctness of portraiture which mere erudition could not have effected. The work, however, is incomplete. In 1799 he published his *Lucinde*, a work, as Mrs Austin describes it, "of fancy, sentiment, and reflection;" in which, however, the very anti-platonic character of his descriptions of love occasioned not a little scandal and censure. In the year 1800 he established himself as a private teacher in Jena, where he delivered a course of philosophical lectures with success. His first poetical compositions, which appeared in the *Athenæum*, seem to have been the productions of this period. In 1801 he published, in conjunction with his brother, August W. Schlegel, two volumes, entitled *Charakteristiken und Critiken*, one of the most popular and pleasing of his works. The second volume includes his "Hercules Musagetes," an elegiac poem of some length; and in 1802 he published a tragedy, *Alarcos*, in which he has tried, with no remarkable success, to impart the severe and gloomy simplicity of Æschylus to a legend of the middle ages. In fact, it is neither as a lyric nor as a dramatic poet that the name of F. Schlegel is likely to be remembered. Goethe, at least, always appeared to estimate the poetical talent of Schlegel at a low standard (*Characteristics of Goethe*, vol. i. p. 120). But the study of the poetry and literature of the west was near about to be exchanged for that of the eastern nations. Following in the footsteps of Sir William Jones, and filled with the idea of the important additions which might be made to Europe by naturalizing, in Germany, the results of Indian research, and of the still greater benefits which he conceived might be derived from the pursuit of Indian literature, philosophy, and antiquities, in an enlarged, philosophical, and at the same time religious spirit, he resolved to devote himself to the study of Sanscrit. He probably overrated, on the whole, both the importance of the labour in which he was about to engage and its probable interest to the public mind. With a view, however, to his intended investigations, he repaired to Paris in 1802, accompanied by his wife, the daughter of the celebrated Moses Mendelssohn, and, with the assistance afforded by the valuable stores of the National Library, and the hints derived from those distinguished orientalists, M.M. de Langlès and Chézy, he is said to have made considerable progress in the study of Persian and Sanscrit poetry. During his residence in Paris, which continued till 1805, he delivered a course of lectures on metaphysics, which met with but partial success. During the same period he wrote a variety of articles on the early Italian, Spanish, Portuguese, and Provençal poetry; and published, in 1804, a collection of the romantic poems of the middle ages, and a series of letters on the different schools and epochs of Christian painting and Gothic architecture, a work for which the temporary concentration of the various treasures of modern art in the Parisian capital afforded ample materials. These letters, which he afterwards revised and enlarged, form one of the most pleasing of his compositions. He takes up the subject nearly where Winkelmann had left it, and performs, in the same spirit of love, the same service for the arts of the middle ages which that critic had done for those of antiquity.

It was at this period of F. Schlegel's life (1805) that he took the step of embracing Roman Catholicism, as Count Stolberg had done a few years before.

In 1808 appeared his work on the *Language and Wisdom of the Indians*. The first part of this work is occupied with a comparative examination of the etymology and grammatical structure of the Sanscrit, Persian, Greek, Roman, and German languages. The second traces the connection of the different religions and philosophical systems that prevailed in the ancient oriental world. The last consists of metrical versions from the sacred and didactic poems of the Hindus. It cannot be denied that this work, with all its learning and sagacity of conjecture, is yet a very imperfect one. The profounder learning of Jacob Grimm has demolished many of the ingenious theories of Schlegel as to the original monuments of the German language. Much, too, has of course been added to Indian learning since it appeared; many of its views have so completely passed into commonly-received opinions, that they have ceased to strike us as novelties; and other truths which are there only hinted at, have been elucidated and confirmed. But it had the merit of opening a comparatively new path in Germany, and perhaps in other countries of Europe. After Schlegel's return from France, he proceeded, in 1808, to Vienna, with the view, it is said, of completing from historical documents an unfinished drama on the subject of Charles V. In the following year he was appointed imperial secretary at the Archduke Charles's head-quarters, and contributed much, by his spirited proclamations, towards rousing the patriotic ardour of the country in the contest against Napoleon. After the unfortunate issue of the war, he resumed his literary activity, and in 1810 delivered his course of lectures on modern history. By many these lectures were considered as his masterpiece. They embodied in a systematic form the various opinions and incidental views which he had thrown out in his earlier essays, and contained, in a more detailed form, the proofs of many of those positions which he afterwards stated in a more brief and general form in his *Philosophy of History*. In 1812 Schlegel delivered, before a numerous and distinguished audience at Vienna, his celebrated *Lectures on the History of Literature*, the work by which he is best known beyond the limits of his own country. Of course a work which exhibits an outline of the literary history of the world, and traces the influence of its various literatures on one another, within the compass of two volumes, cannot descend to much minuteness of detail, or delineate, with that precision which would be desirable, the characteristics of individuals. The style of the work is elegant and enthusiastic without being extravagant. Yet some deductions must be made, both from the impartiality of the work and from the soundness of its views. It is difficult to conceive on what grounds of sound criticism the *Lusiad* of Camoens can be exalted above the *Jerusalem* of Tasso; and still more how the "romantic witchery" of the drama of Calderon, rich and fantastical as it is, can ever be placed on the same level with the profound imagination which combines with this romantic beauty in the theatre of Shakspeare. English literature, with the exception of Shakspeare, can hardly be said to be appreciated at all. French literature, at least after the time of Corneille, is treated with great injustice; Pascal is passed over with a single word; Malebranche is not mentioned at all. And indeed the literature of the seventeenth and eighteenth centuries is discussed in a very perfunctory and unsatisfactory manner. Some of the faults of the work are undoubtedly owing to the strong religious bias of the author. For the Catholic literature of Spain and Italy he shows an undue preference, with a corresponding coldness and indifference towards that of Protestant nations. "Friedrich Schlegel," says Heine, in his lively work on Germany, "has examined all literatures from a lofty point of view; but this high position of his is always on the belfry of the Catholic church; and whatever Schlegel says, you can't

Schlegel.

Schleier-
macher.

help hearing the bells jingle about him, and now and then the croaking of the ravens that haunt the old weathercock." With the *History of Literature* the critical career of F. Schlegel may be said to have closed; for a flattering and somewhat exaggerated criticism on Lamartine's *Méditations Poétiques*, which subsequently appeared in the *Concordia*, scarcely deserves to be noticed as an exception. From 1812 he was much occupied with political and diplomatic employments. Having acquired the friendship and confidence of Prince Metternich, he was employed by him in various diplomatic missions; and for several years after the peace of 1814 he was one of the representatives of the court of Vienna at Frankfort. A pension, with letters of nobility, and the title of councillor-confessor were conferred upon him by the emperor. These diplomatic functions, of course, occasioned a temporary interruption to his literary pursuits; but in 1818 he returned to Vienna, where they were resumed with ardour.

In 1827 he delivered at Vienna another course of *Lectures on the Philosophy of Life*, of which, indeed, an outline had appeared in the *Concordia* for 1820. This work was almost immediately followed by another course of *Lectures on the Philosophy of History*, which have lately been translated into English, and which appear not unworthily of the reputation of the author. Towards the close of the year 1828 Schlegel went to Dresden, where he delivered nine *Lectures on the Philosophy of Language*, in which he farther developed and expanded those philosophical views which he had already laid down in his *Philosophy of Life*. The course, however, was interrupted by death, on the 11th of January 1829.

The genius of F. Schlegel was philosophical and critical, rather than poetical; but he had that species of poetical imagination without which there can be no lofty or useful criticism, which enables the critic to rise above artificial and natural peculiarities, and to judge with truth and certainty upon broad and universal principles. Even when his criticism is imperfect or erroneous, it is often valuable; for it abounds in new and original views, excites the mind to independent speculation, and teaches the habit of viewing literature, the arts, and philosophy, not as isolated subjects of study, but as acting and re-acting with the most important influences upon each other. From his powerful and inventive mind many of the speculations of his brother appear to have been derived. Translations of four volumes of F. Schlegel's works are included in Bohn's "Standard Library." (G. M.—R.)

SCHLEIERMACHER, FRIEDRICH DANIEL ERNST, a philosophic theologian of great eminence, was born at Breslau on the 21st of November 1768. He was the son of a poor army-chaplain in Silesia, who belonged to the reformed or Calvinistic communion; and hence he learned early the meaning of poverty and principle. The earliest instructions of young Schleiermacher were received from his mother, and he betrayed early great quickness and susceptibility. Removing from Pless, on the borders of Galicia, whither his family had gone to reside, and where he had the privilege of enjoying the instructions of a pupil of Ernesti, he was, at the age of fourteen, conducted to the educational establishment of the Moravians, at Niesky. He got through his term of years at this seminary of the United Brethren, with much profit, and no small questioning of the religious tenets taught him at this institution. Meanwhile, he remained lively, earnest, and thoughtful. At the age of seventeen he entered the theological seminary of the Herrnhuter, or Moravians, at Barby; and here he had to wrestle with his old doubts, grown tenfold stronger by reason of the keenness of his own vision. He cut his way through the narrow theological forms of the brotherhood; and proclaims to his father, that he has no chance of becoming a thorough theologian so long as he remains at

Schleier-
macher.

Barby. The army-chaplain, whose mind had never been perplexed with the dark phantom-forms conjured up by religious doubt, answered him in a stern, unsympathizing tone: "O you fool of a son, who has bewitched you that you obey not the truth," and so forth; in what, in another case, would be called a decidedly savage style. This rough upbraiding hurt the poor lad's heart, which was one of the gentlest and tenderest. His days at Barby must now be short, and his religious guides manifest a mournful solicitude for the youthful Schleiermacher, going forth in such wild weather, in such a frail bark as was his to sail in. He must go, however, let the sea rage as it may, and be the bark of what texture it may. Schleiermacher left the Herrnhut communion in 1787, and entered the University of Halle, under the guardianship of his maternal uncle, the pastor Stubenrauch, who seems to have regarded his condition with more favour than had been shown by the army-chaplain. Here he studied with great distinction under Nösselt, Knapp, Eberhard, and Wolf. He paid great attention to philology and antiquities, as essential subordinates, in his estimation, to the study of theology, which was to be the study of his life. In May 1790, the young licentiate undertook a tutorship, till other work might turn up for him. He went to the residence of Count Dohna-Schlöbitten, of Finkenstein, in Prussia, where he spent three fruitful years in educating that nobleman's children. On his removal from Finkenstein, he was engaged for some time at Berlin, as an assistant teacher in the Friedrich-Werder Gymnasium. In the spring of 1794 he went to assist a clergyman at Landsberg on the Wartha, where he gained much distinction as a preacher. Two years afterwards he was brought back to Berlin, to occupy the pulpit of the Charité, the chief hospital in the Prussian capital. Schleiermacher's mind was here exposed to new and stimulating influences, by which his views were widened and his sympathies increased. With his purely ideal views of human life, he would find much to unlearn amid the mixture of rudeness and refinement which met his eye, wherever he turned, among high and low, in the busy life of Berlin. He would come to correct his sweeping contempt for conventionality, and would nourish his love of the society of cultivated men and women. He began his literary career by aiding Sack in his translation of Blair's *Sermons*; by translating Fawcett's *Sermons*, in 1798; and by contributing several papers for the *Athenaeum*, a journal then conducted by the brothers Schlegel. His friendship for the younger Schlegel was formed in 1797, and Schleiermacher's questionable, though innocent, commendation of his novel, *Lucinde*, has rendered their connexion somewhat notorious.

In 1799, Schleiermacher's outward life began. In this year he published his *Discourses on Religion* (Reden über die Religion, an die Gebildeten unter ihren Verächtern), and let the German world know what was yet in store for them. These *Discourses* were very characteristic. They were a product of the personal development of the author up to the time of their publication. F. Schlegel pronounced them the first of their kind in the German language. They were full of energy and fervour, and the doctrines were set forth in a style which, while it reminded one of the recent studies of their author in Plato, Spinoza, Kant, Jacobi, and Fichte, they nevertheless exhibited an uncommon degree of individuality, and were set forth with a singularly brilliant eloquence. They are rather apologies for religion in general, than for Christianity; and they have been again and again accused, in more or less definite terms, of inculcating Pantheism. Certainly here and there he verges almost as close upon the doctrine as those who teach it in express language. But after the explanations which Schleiermacher has given of his more matured opinions, in the third edition of the *Discourses*, no one but the captious will be disposed

Schleier-
macher.

to father over upon the man the production of his youth. It will be seen that this book is essentially a somewhat crude production; which Schleiermacher could only have produced at the time he wrote it. It has a slight smack of *heathenism* about it; but still it possessed the much higher merit of setting forth, in no unmistakable terms, the bases, or essentials, of the theology which he was afterwards to erect upon its foundation. It was full of deep, wide-reaching thought, and was better calculated than all the works that had gone before it to fill the minds of the educated classes with a profound reverence for religion. These *Discourses*, with all their defects, marked a new era in theology; their influence is still fresh, and the impulse which they communicated to the study of theological doctrine and history has not yet been expended. In 1800 he published a profound work called *Monologen, eine Neujahrsgabe*. The Monologues were followed by *Briefe eines Predigers ausserhalb Berlin* (Letters of a Preacher residing out of Berlin), being a reply to a public letter addressed by certain Jews to Teller, the Protestant theologian. He likewise agreed this year to join F. Schlegel in translating Plato, but afterwards undertook the task himself. This German translation of Plato is esteemed by scholars to be the most correct that has appeared in any European language. He wrote at the same time valuable introductions to each of the dialogues which he translated (for he unfortunately did not finish them), displaying a much deeper acquaintance both with the language and the thoughts of his author, than was at all common in the most learned country in Europe. These introductions to the Dialogues of Plato have been rendered into English by Dobson. In 1801 he sent forth a valuable set of *Predigten*, or sermons, which were followed up in succeeding years by six other collections. These discourses were characterized by what was a marked feature in all his productions, a singular luminousness of thought and vividness of expression, such as could only arise from remarkable dialectical gifts, and an uncommon faculty of language. Hence Schleiermacher and the school of theologians which he originated, have been called "Denkgläubigen," in contradistinction to the old school of literalism and pietism which prevailed in Germany at the time he appeared. Schleiermacher removed to Stolpe as court-preacher in 1802, and here he meditated his work on *Morals*, which he published next year under the title of *Grundlinien einer Kritik der bisherigen Sittenlehre*, and wrote his *Zwei unvorgreifliche Gutachten in Sachen des Protestantischen Kirchenwesens*. He declined a call in 1804 from the University of Würzburg, at the request of the Prussian government, which appointed him to the chair of theology and philosophy at Halle. Schleiermacher was driven from Halle in 1806 by the violent political struggles of that year, and on his return to Berlin he bated no jot of high-hearted patriotism, but continued, both in the pulpit and out of it, to denounce in the most unmeasured terms the violent rapacity of their foreign oppressors. During these years he published *Die Weihnachtsfeier, ein Gespräch*, Halle, 1806; *Ueber den sogenannten ersten Brief des Paulus an den Timotheus*, Berlin, 1807; *Ueber Universitäten*, Berlin, 1808; and an Essay on Heracleitus for F. A. Wolf's *Museum der Alterthumswissenschaften*.

In 1809 he was chosen preacher at Trinity Church, Berlin, and next year he was appointed professor of theology in the new university of the same city. He was likewise attached to the Ministry of the Interior for the Department of Public instruction, and was chosen a member of the Academy of Sciences. He was no sooner appointed to his chair in Berlin, than the reforming spirit of his theology began to be felt. In 1811 appeared his *Kurze Darstellung des Theologischen Studiums* (Brief Outline of the Study of Theology), only a few sheets,

but brant full of new thoughts. In this wonderful little treatise, which has been given to the English public by Farrer, Edinburgh, 1850, theology appears under a fresh and inviting aspect by the originality of the lecturer's method and the strength and force of his theological ideas. He divides theology into philosophical, historical, and practical. Under the philosophical head he includes the principles of apologetics and the principles of polemics; under the historical head, he includes exegetical theology, the past history and present condition of Christianity, dogmatic theology, and ecclesiastical statistics; under the practical portion, he includes the principles of church service and of church government. This is perhaps the most thorough distribution theology has ever received. And to the filling up of this brief outline he set himself with great energy. His lectures are described as something wonderful. To his vast sweep of thought, now ranging round the outposts of theological systems, and again darting upon the smallest detail and opening it up to the light, he united immense learning, not of the cumbrous bibliographical sort so peculiar to Germans, but of the living facts and principles of all times, combined with a grand faculty of utterance, which gave the most musical form to the most golden thoughts, holding his hearers in raptures while he spoke, and carrying them breathlessly away with him in his airy chariot of fire. No wonder that lectures like these still live although the speaker has been long silent. Schleiermacher was made secretary to the philosophical class in the academy, and was released from his connection with the Minister of Public Instruction. In 1817 he was chosen president of the synod of Berlin, and wrote his *Ueber die Schriften des Lukas, ein Kritischer Versuch*, Leipzig, 1817 (Critical Essay on the Writings of Luke), which has been translated into English in 1825, said to be by the Rev. Dr Connop Thirlwall, afterwards Bishop of St David's. Schleiermacher was engaged during these years in revising and editing afresh his former works; and in the course of the year 1817-18, he published a number of small polemical writings directed chiefly against Schmalz and Von Ammon. Although by the higher faculties of his nature he was kept free from degenerating into a mere controversialist, yet he relished immensely the occasional flagellation of a fat bishop or of a conceited "Prediger," which he did with approved elegance, spicing his drubbing with tart, attic salt, and letting his subject go just without killing him.

In 1821-22 Schleiermacher crowned his theological labours by the publication of his greatest work, viz., his *Darstellung des christlichen Glaubens nach den Grundsätzen der evangelischen Kirche* (Exhibition of the Christian Faith, according to the principles of the Evangelical Church). In this work we have all the characteristics of his earlier productions, mellowed by the light of a ripper wisdom and a more matured Christianity. He gives a decided prominence from first to last to the positive character of the Christian system of belief, and has contributed in a high degree to give force to the genuine truth of the Christian faith. Twisten justly observes that "Schleiermacher, by conducting the science of dogmatics to the facts of the Christian consciousness, as its basis and its true object, secured faith itself against the assaults of a science which mistakes its own boundaries, as well as restored to the system of faith its own proper independence." The *Studien und Kritiken*, a genuine product of his spirit, was begun in 1828. In 1833, Schleiermacher visited England and opened the German chapel at the Savoy. He had not returned many months to Germany when he was seized with his last illness. His bodily constitution, which never had been strong, was now worn so much by the ceaseless activity which characterized him, that it became evident to his friends they

Schleier-
macher.

Schleitz
||
Schlözer.

must soon part with that gentle and loving heart which had beat so true amongst them. As he lay on his death-bed, he gave a short exhortation to the friends who were present to join him in celebrating the Lord's Supper, and after repeating the words, "Take, eat," &c., he said, "Upon those words of Scripture I abide; they are the foundation of my faith." He laid himself back upon his pillow, and in a few minutes he was taken away from among men. This was on the 12th of February 1834. His body lies interred at some distance from the city on its south side. A simple monument, with a marble bust executed by Rauch, marks the spot where one of Germany's greatest sons reposes. The whole of his works, published and unpublished, were issued after his death in 1835.

SCHLEITZ, the chief town and residence of the prince, but not the seat of the government of Reuss-Schleitz, on the Wiesenthal, 37 miles S.E. of Weimar. It contains an ancient church, with the vaults of the ducal and princely family, a normal seminary, and a Latin school. Woollen and cotton cloth, leather, and beer are manufactured here, and there is a considerable trade. Pop. 5000.

SCHLESWIG (Danish, *Slesvig*), a seaport of Denmark, capital of the duchy of the same name, at the head of the Schlei, a long narrow inlet of the Baltic, 23 miles N.W. of Kiel, and 70 N.N.W. of Hamburg. It has a beautiful situation, being almost surrounded by the water; and is neatly but irregularly built, mostly of brick. There are three distinct parts of the town,—*Altstadt*, called the Old town, the *Loffuss*, and the *Friedrichsberg*. Among the public buildings, the most remarkable is the cathedral, containing the monuments of many dukes and bishops of Schleswig, and an altar-screen beautifully carved in wood. The large and handsome old castle of Gottorp, once the ducal residence, stands on an island connected with the town by two dams. It is now used for barracks, and its park for an exercise-ground. East of the town stands the nunnery of St John, for noble ladies, the only one now remaining of the conventual establishments in the duchy. It possesses extensive lands in the vicinity. Schleswig has also a gymnasium, deaf and dumb hospital, lunatic asylum, and other benevolent institutions. Manufactures of sail-cloth, woollen cloth, lace, china, earthenware, leather, &c., are carried on here, and there is a considerable trade and navigation. The harbour has been improved, but is only accessible to small vessels. About 100 families, who live in a separate part of the town, are employed in fishing. Schleswig is a very old place, having been in existence as early as 808; and for nearly six centuries it was the chief commercial city in Denmark, and a member of the Hanseatic League. The deposits of mud that obstruct the mouth of the Schlei have been the chief cause of its decline. Pop. 11,600.

SCHLESWIG, or SLESWICK, DUCHY OF. See DENMARK.

SCHLÖZER, AUGUST LUDWIG VON, a German historian, was born, on the 5th of July 1737, at Jagstadt, in Hohenlohe-Kirchberg. He lost his father at a very early age, but the lad's education was not neglected. In 1751 he was sent to the University of Wittenberg, where he displayed a strong liking for oriental languages. He went to Göttingen to study theology, and, after continuing there for the next two years, he, in 1756, engaged himself as tutor to a Swedish family, and started forthwith for Stockholm. While engaged on this occupation he contrived to gain time for the writing of a *History of Commerce* in Swedish, which he published at Stockholm in 1758. Next year he returned to Göttingen, with the full intention of proceeding to Asia on a philological mission, an idea which he had long entertained. But in 1761 this grand design was overthrown by a proposal from Müller, historiographer to the Emperor of Russia, to become tutor in his family, and to assist him in his literary projects, with the prospect of a professorship in the academy of St Petersburg. The great progress of

Schlözer, or some other cause, roused the jealousy of his employer, and he pursued him, on his retiring from his tutorship, with the most virulent opposition. In 1764 he was offered a professorship in the University of Göttingen by the influence of his friend, J. D. Michaelis. But Müller again appeared, and by his interference Schlözer was withheld from leaving the Russian capital. In 1765, despite the persevering insinuations of Müller, he was chosen professor of Russian history to the academy of St Petersburg. This situation he only held for two years, when, turning his back on Müller and the Russian capital, he proceeded to Göttingen, where he had just been elected to the chair of political science. Here a new field of activity opened up to him, and he worked in it with great energy and success for a long series of years. His works, published during this period, are written in a lively though somewhat coarse style, and they still attract a fair share of the attention of the reading public of Germany. His historical works include *Allgemeine Nordische Geschichte*, 2 vols., Halle, 1772; *Nestor's Chronik*, down to 980 A.D., Gott., 1802-9; *Weltgeschichte in Auszuge und Zusammenhange*, Gott., 1792-1802; *Vorbereitung zur Weltgeschichte für Kinder*, Gott., 5th ed. 1800. His political writings include his *Briefwechsel*, 10 vols., 1779-82; and his papers in the journal *Staatsanzeigen*, 18 vols., from 1782 till 1793. In 1804 he was raised to the rank of a nobleman by the Emperor of Russia, the father of Russian history "no longer standing in his way." He died on the 9th of September 1809. (See A. L. Von Schlozer's *Oeffentliches und Privatleben aus Originalurkunden*, by his son, Carl von Schlozer, 2 vols., Leipzig, 1828.)

SCHLÜSSELBURG, a town of European Russia, in the government and 21 miles E. of St Petersburg, at the point where the Neva issues from Lake Ladogo. It is partly built on an island, on which stands an old fortress, frequently used as a state-prison. The town is chiefly built of wood, and has manufactures of chintz and calico, and some trade with St Petersburg. Pop. 4000.

SCHMALKALDEN, a town of electoral Hesse, in the province and 34 miles E.N.E. of Fulda, among the Thuringian Mountains, at the confluence of the Schmalkalde and Stille. It is an ancient town, still encircled by its walls and moat, and containing antique wooden houses, with lofty carved gables. Their lower portions are almost all smiths' shops, as the inhabitants for the most part are of that occupation. The chief buildings are a large Gothic church and two castles. One of the inns is the place where the celebrated Schmalkaldic League was formed by the Protestant princes in 1531, and the house is shown where the articles were drawn up. There is also a town-hall, hospital, schools, &c. The chief productions of the place are iron, steel, and cutlery; for not only the town, but the whole valley may almost be considered as one great smithy. Pop. 5500.

SCHMÖLLN, a town of Saxe Altenburg, on the Sprotta, 7 miles S.W. of Altenburg. It is surrounded by walls; and contains two churches, weaving and spinning works, and manufactories of woollen cloth. Pop. 4049.

SCHMÖLNITZ, a town of Hungary, in the county of Zips, in a mountain-enclosed valley, 21 miles S.S.E. of Leutschau. It is a mining town, built of wood, and the seat of an imperial board of mines, and of a mint for copper coins. There is also a high school and an hospital. Silver and copper are the minerals obtained here. Pop. 4530.

SCHNEEBERG, a town of Saxony, in the circle of Zwickau, on a hill near the western Mulde, 20 miles S.S.W. of Chemnitz. It is well built, and has a Gothic church of the sixteenth century, said to be the largest in Saxony. In it is the masterpiece of the elder Cranach—an altar-piece representing the crucifixion, and other specimens of Protestant art. There are also a gymnasium and other schools, orphan hospital, &c., in the town. The inhabitants are for

Schlüssel-
burg
||
Schnee-
berg.

Schneide-
mühl
||
Schnorr
von Karols-
feld.

the most part employed in mining; silver, cobalt, iron, and tin being the chief ores obtained. The total value of the minerals obtained in 1854 was L.2120. Various manufactures are carried on here, the principal of which are those of lace and chemical articles. Pop. 7452.

SCHNEIDEMÜHL, or PILA, a town of Prussia, province of Posen, in the circle and 52 miles W. of Bromberg, on the Kuddow. It has a castle, two churches, and a synagogue. Manufactures of woollen cloth, lace, hosiery, hats, and leather, and some trade in cattle, are carried on here. Pop. 5474.

SCHNEIDER, JOHANN GOTTLÖB, an eminent German philologist and naturalist, was born on the 18th of January 1750, in the village of Kolm, in Saxony, whence the application of the epithet "Saxo," which he joined to his name on the title-page of his works. His father, who was a village mason, could do little to advance his prospects; but his uncle, who was in better circumstances, took him under his charge, and, after having prepared him for college, he sent him to the University of Leipzig to study law, at the age of eighteen. Ancient literature had more attractions for him than the pursuit of law, and he resolved to prosecute that study with untiring diligence. His first work was his *Anmerkungen über den Anacreon*, Leipzig, 1700; and it was followed next year by *Periculum Criticum in Authologiam Constantini Cephala*. Schneider left Leipzig for Göttingen, where he lived in great straits, till his engagement to assist Brunck, at Strasburg, with his edition of the Greek poets. Here he studied anatomy, botany, and zoology, and published works on Pindar and Plutarch in 1774 and 1775. In 1776 he was called to the chair of philology and eloquence in the University of Frankfurt-on-the-Oder. He continued with unabated zeal his inquiries into the natural history of the ancients, and omitted no opportunity of informing himself regarding his favourite science. He began his work in his new sphere by publishing *De Dubia Carminum Orphicorum Auctoritate et Vetustate*. He likewise edited Demetrius Phalereus, Ælian, Xenophon, Nicander, and Aristotle on the history of animals and on politics; Theophrastus, Orpheus' *Argonautica*, Æsop, Epicurus, and Oppian. He also wrote *Eclogæ Physica*, 2 vols. 8vo, 1801, which contained the most important parts of natural history known to the ancients. A complete list of his works may be seen in Meusel's *Gelehrtes Deutschland*; and in the *Biographie Universelle*, which contains a life of him by Cuvier and Schoell. On the death of Bredow in 1816, the office of chief librarian to the university (then removed to Breslau) was conferred on Schneider, who held it till his death in 1822.

SCHNORR VON KARLSFELD, JULIUS, an eminent German painter, was born at Leipzig on the 26th of March 1794. His father, who was likewise a painter of some note, designed him for a different profession; but his strong attachment to art at an unusually early age induced the father to change his mind, and he was accordingly sent to study in the Academy of Painting at Vienna. Having shown considerable artistic ability at that institution, he proceeded to Rome in 1815, and attached himself to the school of young German artists, then on the ascendant in that ancient city of art. Schnorr was reckoned among the most promising of these artists, and he was chosen, with Cornelius and Overbeck, to paint the walls of the villa Massimo at Rome in fresco, with designs from the great Italian poets Dante, Ariosto, and Tasso. Schnorr had the good fortune to gain an introduction to Ludwig, afterwards King of Bavaria, who employed him to assist in decorating the great works on which he was then engaged at Munich. His first task was to paint a series of frescoes from the ancient German poem, the *Nibelungen Lied*, to adorn the state apartments of the new palace. This series of paintings occupy five chambers, each bearing the name of the

portion of the *Lied* depicted in it. There is the "Entrance Hall," the "Marriage Hall," the "Hall of Treachery," the "Hall of Revenge," and lastly, "the Hall of Lamentation." These paintings, all of which were executed by Schnorr and his pupils, attract great attention, and perhaps they are the most generally popular of all the great modern pictures in the galleries of Munich. He likewise, while these frescoes were in progress, was engaged upon that portion of the "Fest-Saalbau," devoted to an illustration of the history of Charlemagne, Frederick Barbarossa, and Rudolf of Hapsburg. He executed only the more important pictures in this series, the rest being painted by his pupils after his designs. They display, however, in their magnificent abundance, great technical skill and vigour of imagination; but they exhibit glaring defects of colouring and much redundancy of drapery. Schnorr had been appointed professor of historical painting in the Academy of the Fine Arts at Munich in 1827, and this situation he continued to fill till 1846, when he was chosen director of the Picture Gallery, and professor of the fine arts in Dresden. He died on the 13th April 1853.

SCHNURRER, CHRISTIAN FRIEDRICH, was born at Kanstadt, in Wurtemberg, on the 28th of October 1742. He began his career as an academical teacher in 1762, at his native University of Tübingen. He subsequently visited Holland, England, and France, and on his return in 1775 he was elevated to the chair of philosophy in Tübingen. He likewise lectured on oriental languages, of which he had an accurate knowledge, was chosen ephorus of the theological faculty in 1777, and some years later he was made chancellor of the university. Schnurrer lost, however, his academical position by his freedom in criticising the proposed constitution of Wurtemberg. He was a man of great learning, and wrote pretty extensively on historical and theological subjects, notwithstanding his numerous engagements. He took an active share in the *Tübinger Literarische Nachrichten*, and published a *Bibliotheca Arabica*, which evinced great acquaintance with his subject. His Life was written by Weber, Kanstadt, 1823.

SCHÖFFER, PETER. See PRINTING.

SCHOLIAST, or *Commentator*, a grammarian who writes *scholia*, that is, notes and glosses, upon ancient authors who have written in the learned languages.

SCHOLZ, JOHANN MATTHIAS AUGUST, a German philologist, was born at Kapsdorf, in Prussian Silesia, on 8th February 1794. He studied languages and theology at the Roman Catholic College of Breslau. He began his critical labours on the text of the New Testament, and visited Austria, England, France, Switzerland, and Italy, in quest of the necessary materials. His *Novum Testamentum Græce* appeared in 2 vols., in 1830-35. Having joined the expedition under Minutoli for the exploration of Egypt, the travellers subsequently disagreed and parted; but Scholz pursued his journey through Egypt, Palestine, and Syria, and published a selection from his diary in 1822. In 1823 he was chosen professor of theology at the University of Bonn. He published his *Handbuch* of Biblical Archæology in 1834, and died in 1852.

SCHOMBERG, FRIEDRICH ARMAND, DUKE OF, a distinguished officer, the son of Count Schomberg and a daughter of Lord Dudley, was born in 1612, but others, without any reason, adopt the year 1619. He began his military career under Frederick-Henry, Prince of Orange, and served successively under the courts of Sweden, the Netherlands, France, Portugal, Prussia, and England, with the greatest lustre. In France he was accounted second only to such men as Marshal Turenne and the Prince of Condé; and in the subsequent campaign with Spain, he humbled that country so much that it solicited a peace in 1663, and acknowledged the house of Braganza as the just heirs to the crown of Portugal. For this piece of distinguished

Schnurrer
||
Schomberg.

Schömburg
||
Schools of
Music.

service he received a pension of L.5000 from the kingdom of Portugal, with reversion of it to his heirs. In 1673, after an unsuccessful attempt to obtain command in England, he betook himself to the Netherlands, and subsequently to France. Involved in the persecution which ensued of the French Protestants, the old soldier was compelled by the Edict of Nantes to seek refuge elsewhere. After trying Portugal and Holland, he was chosen commander-in-chief of the forces of the elector of Brandenburg. He joined the prince of Orange on his expedition to England in 1688, and was made commander-in-chief of the English forces. The following year he was made baron, earl, marquis, and duke successively, and had the honour of L.100,000 voted to him by the English House of Commons. In the month of August, he was sent to Ireland to oppose the progress of the late King James II., who ranged the country with a force three times the strength of that possessed by the Duke of Schomberg. He accordingly posted himself at Dundalk, five or six miles from the hostile army, where he spent some six weeks in utter inaction, which lost him the half of his army. For this conduct he was severely blamed by some; but the subsequent battle of the Boyne, fought on the 1st July 1690, effectually wiped out any stain upon his previous conduct; but unfortunately it proved too late for the Duke of Schomberg. He was killed while gallantly leading a body of French Protestants across the river. Thus died a man who had done signal service to Protestant Europe during his long career, and who had the reputation, on his appointment to command the English forces, of being "the greatest living master of the art of war." (Macaulay's *History of England*, vol. iii., p. 195, 1858.)

SCHOMBERG, or SCHONBERG, a town of Austria, Moravia, in the circle and 27 miles N.N.W. of Olmutz. It has a castle, belonging to the princes of Liechtenstein, to whose family, in 1621, the town and district was given by Ferdinand II. In the vicinity are iron-mines; and in the town, manufactories of cotton, linen, and needles; also bleach-fields, &c. Pop. 5388.

SCHOOLS. See NATIONAL EDUCATION and UNIVERSITIES.

SCHOOLS OF MUSIC. The establishments themselves, with their buildings and apparatus, their masters and pupils, are called conservatories or academies. In another sense, the term *school of music* is applied to the district or the country in which a particular style and manner of composition has been practised and taught by eminent musicians. Thus, we speak of the Flemish, the German, the French, the Italian schools of music. In Flanders arose the oldest school of music in Europe. The greatest contrapuntists of the fourteenth and fifteenth centuries were Flemings, many of whom visited or established themselves in various countries, more especially the Italian states, practising and teaching their art. Thus, the famous Flemish composer, Josquin Deprès, was established in the chapel of Pope Sixtus IV. from 1471 to 1481; and Adrian Willaert founded the Venetian school of music in 1527. After the close of the seventeenth century, Flanders ceased to possess a distinctive school of music. According to Padre Martini (*Saggio di Contrappunto Fugato*, parte 2^{da}, pagine 207-8), the Neapolitan school of music was founded by King Ferdinand of Arragon in the latter part of the fifteenth century. In the same work, page 194, Padre Martini reckons five great schools of music in Italy, subdivided into a great number of particular schools named after distinguished masters. 1. The Roman School of Palestrina, the two brothers Nanini, O. Benevoli, and F. Foggia. 2. The Venetian School of Adrian Willaert, Zarlino, and Lotti. 3. The Neapolitan School of Rodio, Scarlatti, Leo, and Durante. 4. The Lombard School of Porta, Monteverde, Ponzio, and Vecchi. 5. The Bolognese School of Rota, Giacobbi, Colonna, and Perti. To these last the name of

VOL. XIX.

Martini himself should be added. Some writers divide the schools of Italy geographically into three, viz.—1. The School of Lower Italy (the Neapolitan), which is distinguished by variety of expression; 2. That of Middle Italy (the Roman and Bolognese), the character of which is purity and grandeur of style; 3. That of Upper Italy (the Venetian and Lombard), which was marked by its forcible colouring. In the last century there were at Naples four conservatories of music, which, in 1806, were all united into a royal academy of music. In 1818 the writer of this article found it in a very low and useless condition. At Venice, in 1819, he found that the only conservatory remaining (out of four existing in the last century) was that of La Pietà, under Signor Agostino Perotti, who said that it was starved by the Austrian government. At Bologna, in 1819, the musical academy was the Liceo, and Padre Mattei, the successor of P. Martini, was then old and feeble. At Milan, in 1819, the conservatory (founded in 1807) was thriving and well conducted. It is now the only important conservatory remaining in Italy. (See CONSERVATORY, MARTINI, and MATTEI.) (G. F. G.)

SCHÖNEBECK, a town of Prussia, in the province of Saxony, circle and 10 miles S.S.E. of Magdeburg, on the left bank of the Elbe, and on the railway between Magdeburg and Leipzig. It is an old town, and contains a brewery, distillery, paper-mills, and manufactories of white-lead and chemical substances. But it is chiefly remarkable for its salt-work, which is the largest in the kingdom, employing one thousand men, and yielding yearly about 672,000 cwt. of salt. Pop. 8526.

SCHÖNHAIDE, a town of Saxony, in the circle of Zwickau, among the Erz Mountains, 15 miles E. of Plauen. It has manufactories of nails, tin ware, brushes, lace, embroidery, &c. Pop. 4468.

SCHÖNLINDE, a market-town of Bohemia, in the circle and 36 miles N.N.E. of Leitmeritz. It has manufactories of linen, woollen, and cotton fabrics, stockings, and yarn; also bleach-fields; and in the vicinity there are stone-quarries and alum-mines. Pop. 4107.

SCHOOTEN, FRANCIS, a Dutch mathematician of some note, regarding the date of whose birth or life nothing almost is known. He must have flourished during the seventeenth century, for his death is known to have taken place in 1659. He was professor of mathematics at Leyden, and taught there, at an unusually early period, the algebra of Descartes and the infinitesimal calculus. He published, in 1646, a tract on the conic sections; and in 1649 a Latin translation, coupled with a learned commentary on Descartes' Geometry. In 1651 were published his *Principia Matheseos*; and in 1657 his *Exercitationes Mathematicæ*, which contained some curious and interesting examples of the application of algebra to geometry.

SCHOTT, ANDREW, a learned Jesuit, was born at Antwerp on the 12th of September 1552. He studied philosophy at Louvain, and subsequently became teacher of rhetoric there, but the disturbances in the Low Countries obliged him to retire to Douay in 1577. Shortly after we find him in Paris assisting Busbecq in his literary pursuits. After spending nearly two years in the French capital, he went to Spain, and obtaining the intimacy of some persons of influence about the court of Philip II., he was made professor of Greek at Toledo, and afterwards was elevated to the chair of Greek and Rhetoric in Saragossa. Becoming a Jesuit in 1586, he taught theology for some time, until an invitation to Rome induced him to leave Spain. He was made professor of rhetoric in the Jesuits' college of the Italian capital, where, after remaining for three years, he obtained leave to proceed to his native town of Antwerp. Here he spent the rest of his days in literary engagements. He died on the 23d of January 1629. Schott, who is more celebrated for learning than genius,

4 z

Schönebeck
||
Schott.

Schrevelius was a man of simple manners and of an industrious life. He was greatly devoted to letters, and although a Jesuit, he esteemed it always an honour to be introduced to any man who had the character of being a scholar, without too nicely inquiring whether he was a Roman Catholic or a Protestant. His works amounted in all to forty-seven, of which the following are the most important:—*Laudatio funebris Ant. Augustini, Archiep. Tarraconensis*, Leyden, 4to, 1586; *Vitæ comparatæ Aristotelis ac Demosthenis*, Augsburg, 4to, 1603; *Hispania Illustrata*, Frankfurt, 4 vols., 1603–8; *Thesaurus*, from the best authors, Antwerp, 1607; *Hispaniæ Bibliotheca*, Frankfurt, 4to, 1608; *Adagia*, a collection of Greek proverbs, Antwerp, 1612; *Observationum Humanarum libri quinque*, Hanau, 1615; *Tabulæ rei nummaræ*, Antwerp, 1616. Schott likewise edited numerous ancient authors, such as Aurelius Victor, Pomponius Mela, Orosius, St Basilus, and Theophylactes.

SCHREVELIUS, CORNELIUS, a laborious Dutchman, who was born about 1615, and who has published some editions of the ancient classics, more distinguished for elegance than accuracy. His *Lexicon Manuale*, which is full of blunders, but which was a good book for its day, is esteemed the best of all his works. He died in 1667.

SCHUJA, a town of European Russia, capital of a circle in the government and 60 miles N.N.E. of Vladimir, on the Tesia, which is here crossed by two handsome bridges. It contains five churches, several schools, and an hospital. It is chiefly, however, as a manufacturing town that Schuja is remarkable; it had in 1855 no less than 65 manufactories, among which were 18 for weaving, 10 for calico-printing, 4 for tanning, &c. The total value of goods manufactured here in 1855 was about L.500,000. Schuja is thus the most important manufacturing town in Russia, and has been distinguished from a remote period for its industrial activity, and the intelligence of its inhabitants. Pop. 8414.

SCHULTENS, ALBERT, professor of Hebrew and of the oriental languages at Leyden, and one of the most learned men of the eighteenth century, was born at Groningen in 1680, where he studied till the year 1706, and thence continued his studies at Leyden and Utrecht. Schultens at length applied himself to the study of Arabic, both printed and in manuscript, in which he made great progress. A short time afterwards he became minister of Wassenaar; and in two years professor of oriental languages at Franeker. At length he was invited to Leyden, where he remained till his death in 1750. He wrote many learned works, the principal of which are—his *Commentarii* on Job, 2 vols., 1737; on the Proverbs, 1748; and his *Origines Hebraeæ*, 2 vols., 1724–38; *Vetus et regna Via Hebraizandi*, Leyden, 1738; *Animadversiones philologicæ et criticæ ad varia loca Veteris Testamenti*, 1769. Schultens discovered in all his works sound criticism and much learning. He maintained against Gousset and Driessen, that in order to have a perfect knowledge of Hebrew, it is necessary to join with it not only the Chaldaic and Syriac, but more particularly the Arabic.

SCHULTENS, *Henry Albert* (1749–1793), grandson of the learned orientalist, likewise attained to very considerable reputation in his grandsire's footsteps.

SCHULTZE, ERNST CONRAD FRIEDRICH, a young German poet of distinction, was born at Celle on the 22d of March 1789. Of a wayward enthusiastic character, he spent his school days in comparative idleness, reading only the chance volumes of romance and chivalry which came in his way. His conduct did not materially alter at the University of Göttingen, whether he was sent in 1806. He gained the notice of Bouterwek, who was struck by some college exercises given in by him; but to the rest of the professors he was in a measure unknown. He occupied his time while living at Göttingen in the composition of a

poem called *Psyche*, in which he caught the charming style of the poet Wieland. Always extravagant, he resolved to immortalize a youthful attachment which he had formed, the object of which had been removed by an early death, by writing a great poem. This composition, which he called *Cecilia*, after the name of the departed, abounds in passages of uncommon beauty and power; but its plan is wild and improbable, and it is altogether beyond the range of ordinary sympathy or of ordinary interest. A subsequent poem, *Die Bezauberte Rose* (The Enchanted Rose) obtained the prize held out by the publishers of *Urania* in 1818. This is unquestionably his best production. He fell a victim to consumption, and died at Celle on the 22d of June 1817, in his twenty-eighth year.

SCHUMACHER, HEINRICH CHRISTIAN, a Danish astronomer of distinction, was born at Bramstedt in Holstein, on the 3d of September 1780. Having early distinguished himself in mathematics and astronomy, he was chosen, at the age of thirty, professor extraordinary of astronomy at the University of Copenhagen. Called to the University of Mannheim in 1813, he returned two years later to Copenhagen, where he was appointed professor of astronomy and director of the university. He was employed by the Danish government in 1817 on the mathematical survey then in progress through their dominions, and received the superintendence, from the Royal Scientific Society of Copenhagen, of the survey and mapping of Holstein and Lauenburg. In 1824 he was engaged on fixing the measure of differences between the observatories of Greenwich and Altona. The king had, in 1821, built for Schumacher a very convenient observatory at Altona, where he resided till his death in December 28, 1850. He had commenced the publication in 1813 of the *Astronomische Nachrichten*, a journal which still exists, and which embraces the astronomical facts and discoveries of the whole world. A good example of his patience and correctness as an astronomer will be found in his *Astronomische Hülftafeln*, issued during the nine years previous to 1829. From 1836 he aided Bessel in editing the *Astronomischen Jahrbuchs*. Schumacher was a man who united genius with modesty, and liberality with courtesy. He was easy of access, and he never ceased to aid by his advice all who sought access to him to ask his counsel.

SCHWABACH, a town of Bavaria, in the circle of Middle Franconia, on a river of the same name, an affluent of the Regnitz, 10 miles S.W. of Nuremberg. It is a well-built old town, encircled by walls, and entered by four gates. In the market-place is a handsome fountain erected in 1716. The Gothic parish church is interesting, and contains some valuable old paintings. There are various other places of worship and schools, a town-hall, and several hospitals. Manufacturing industry is actively carried on, especially that of needles, of which it is the principal seat, not only in Germany, but probably in Europe. There are produced weekly 4,000,000 of ordinary needles, and 100,000 English darning, packing, and other needles. There are also made here hosiery, gold and silver lacc, &c. This place is memorable in the history of the Lutheran Church. At Schwabach the earliest Protestant confession was drawn up by Luther in 1529. Pop. 7000, many of whom are Jews.

SCHWANTHALER, LUDWIG MICHAEL, an eminent German sculptor, descended from a family of Tyrolese artists, was born at Munich on the 26th of August 1802. Having early received a good education, he entered duly his father's studio to learn the family calling. His free notions of art are said to have disgusted the director of the Munich Academy of Fine Arts, who urged his friends to induce him to pursue some other profession, where his talents would not be likely to render him ridiculous. So much for the insight of academy directors. Schwanthaler, by his father's death in 1821, was compelled to forego the counsel of the Munich director, and to adhere to his father's

Schumacher
or
Schwanthaler.

Schwarz. business for the support of his family. He shortly afterwards proceeded to Rome, where he derived much benefit from the friendship of Thorwaldsen. On his return he was employed, through the influence of Cornelius, to execute two extensive bassi-relievi friezes for the Glyptothek. He produced about this period a statue of Shakspeare for the theatre, and a basso-relievo frieze of the Apotheosis of Bacchus, for the palace of Duke Maximilian. He revisited Rome in 1832, to complete Rauch's design for the south pediment of the Walhalla, and to execute other commissions for King Ludwig's new palace. In 1835 he was chosen professor of sculpture to the academy of Munich; and from that period till the day of his death, he displayed uncommon industry and genius in the execution of designs for his art-loving patron, King Ludwig. The northern pediment of the Walhalla at Ratisbon contains a work of great sculptural merit from the chisel of Schwanthaler, called the Hermann-Schlacht, a fine rendering of old Teutonic history. He likewise executed various statues and caryatides for the Walhalla, and numerous cartoons and friezes for the Neue Königsbau, consisting of compositions from Æschylus, from Sophocles, from Aristophanes, and from Hesiod. He likewise ornamented many parts of the Fest-Staalbau, the Pinakothek, and the Neue-Kunstanstellungs-Gebäude, and the magnificent Ludwigs Kirche. For the latter he modelled statues of Christ and the four Evangelists, St Peter, and St Paul. He likewise erected numerous monumental statues for public and private purposes throughout the greater part of Germany, among which we may mention those of Mozart at Salzburg, of Goethe at Frankfurt, and of Jean Paul Friedrich Richter at Baireuth. But his greatest work, beyond all question, was his colossal statue of Bavaria, executed for his native city, representing a maiden crowned with an oak-garland, in the centre of the Bavarian Hall of Fame. This vast work was designed by Stiglmeier, and begun in 1844. It was inaugurated on the 9th of October 1850, nearly four years after Schwanthaler had died. This work is alike remarkable for its dimensions and its grandeur; and the artist seems to have lavished on it all the wealth of his mind. It was the last work on which he was occupied, and it will remain the most signal monument of his genius. He died on the 17th of November 1848, worn out by ill health and ceaseless industry. He bequeathed to the Academy of Fine Arts of Munich his studio and models. The Crystal Palace contains casts of the head of his "Bavaria," and of his "Shield of Hercules," besides various other products of Schwanthaler's skill.

SCHWARZ, CHRISTIAN FRIEDRICH, an eminent Protestant missionary, was born October 8, 1726, at Sonnenburg, a small town in the Electorate of Brandenburg. In his eighth year he entered the grammar school of his native place, and in a few years was removed to an academy of higher pretensions at Cüstrin. In 1746 he repaired to Halle, intending to become a pupil in the grammar school of the Orphan House, founded by Augustus Francke. But the missionary Schultz, who had recently returned from Madras, persuaded him to enter the university, where he attended the lectures of Michaelis and other professors of note, though still an inmate at the Orphan House. Schultz, who had been twenty years in India, was projecting an edition of the Tamul Bible, and prevailed on Schwarz to commence the study of that language, in order to assist him in bringing the translation through the press. His attention was thus directed to foreign missions, and at the suggestion of Professor Francke (son of the founder of the Orphan House) he formed the intention of devoting himself to this department of Christian labour. Before making his decision he visited Sonnenburg, to obtain his father's consent, which, after serious deliberation, was cordially granted. Schwarz gave a pledge of the disinterested spirit which animated his future course by renouncing his

share of his father's property in favour of his brothers and sisters. After spending some months at Halle he proceeded, August 8, 1749, to Copenhagen, for the purpose of receiving ordination in the Danish Church, to which the mission he was about to join belonged. In December he and two other missionaries repaired to England, with the twofold object of acquiring the English language and of obtaining the patronage of the Society for promoting Christian Knowledge, which had previously rendered important aid to the mission on the Coromandel coast. Early in 1750 they proceeded on their voyage, and arrived at Tranquebar July 30. Within four months from that time Schwarz preached his first sermon in the Tamul language. Though Tranquebar continued for some time to be his head-quarters, he paid frequent visits to Tanjore and Trichinopoly,—to the latter place he removed in 1766, and remained there about twelve years. He then left for Tanjore, where he spent the last twenty years of his life. At Trichinopoly he acted as chaplain to the garrison, and so great was his influence that they erected a church for his use capable of holding from 1500 to 2000 persons. The government of Madras allowed him a salary of £100 per annum, which he devoted to the erection of a mission-house and school-room; and when these were completed, he applied one half of it to the relief of the poor. In 1769 he was introduced to the Rajah of Tanjore, who frequently held conversations with him on religious subjects, and though he never embraced Christianity, always countenanced Schwarz in his missionary labours. On one occasion he observed, "He makes out our gods to be downright demons. We must keep him here to instruct this foolish people." He would have made use of Schwarz's mediation with the English, but was opposed by the officers of his court. "Padre," he said, "I have confidence in you, because you are indifferent to money." Just before his death he committed to him the education of his adopted son and successor. Schwarz discharged his trust in a most effective manner, and succeeded in establishing the claims of the young prince to the throne, when the regent his uncle had attempted to set them aside. In 1779 he was called by the Madras government to undertake a private embassy to Hyder Ali. "Do not send me," said Hyder, "any of your agents, for I do not trust their words or treaties; but if you wish me to listen to your proposals, send me the missionary of whose character I have heard so much from every one: him I will receive and trust." The nabob answered all the questions put to him by Schwarz in a very straightforward manner, and on his leaving, after a stay of three months, presented him with 300 rupees to defray the expenses of his journey; but in accordance with his resolution "to keep his hands undefiled by any present," he appropriated the sum to founding an English orphan school at Tanjore. When Hyder invaded the Carnatic, the inhabitants were reduced to the greatest distress—on the one hand by the invader, on the other by the combined exactions of the English and their own ruler, and even the garrison at Tanjore was almost in a state of starvation. In this extremity Schwarz requested the cultivators of the surrounding districts to send in their cattle, simply pledging his word for their payment. In two or three days a thousand bullocks were thus obtained.

After labouring for nearly half a century in his self-denying vocation with an assiduity which places him in the first rank of modern missionaries, Schwarz died February 13, 1798, full of years and of honours. His direct success was perhaps greater than that of any other Protestant missionary in India; the converts from idolatry through his agency amounted to several thousands. The part he took in political transactions was evidently forced upon him, and prompted in no degree by worldly ambition. No man probably ever won such esteem and reverence from all parties,

Schwarz-
burg.

though "he deprecated posthumous praise, and was in constant dread of fame." Mohammedans and Hindoos vied with his converts and countrymen in extolling his virtues and deploring his decease. The Rajah of Tanjore erected a monument, executed by Flaxman, in the mission church, in which he is represented as grasping the hand of the dying missionary, and receiving his benediction. The East India Company also sent out a splendid monument by Bacon, which was placed in St Mary's church at Madras. (*Memoirs of the Life and Correspondence of Schwarz, &c.*, by Hugh Pearson, D.D., 3d edit., Lond. 1839.) (J.E.R.)

SCHWARZBURG, a portion of Germany, geographically divided into a northern and a southern part; and politically into the two principalities of SCHWARZBURG-RUDOLSTADT and SCHWARZBURG-SONDERSHAUSEN. The northern portion, called the Lower County (*Unterrherrschaft*), lies close upon the valley called *Guldene Aue*, and is entirely surrounded by Prussia and Saxe-Coburg-Gotha; the southern or Upper County (*Oberherrschaft*) lies on the northern slope of the Thuringian Mountains, and is encircled by the Saxon duchies, having Weimar on the N., Altenburg on the E., Meiningen on the S.E. and S., and Gotha on the W. The country is divided between the principalities as follows:—

	Sq. miles.	Pop. 1855	
Rudolstadt, upper county,.....	285	54,012	
" lower do.	85	14,962	
	370	68,974	
Sondershausen, lower county,.....	189	35,127	
" upper do.	138	26,325	
	327	61,452	
Total of both principalities,	697	130,426	

The lower county is traversed by a chain of hills called the Hainleite, stretching from the Harz to the Unstrut. They are well wooded, and at the highest part reach the height of 1419 feet above the sea. Here, also, is an isolated peak called Kyffhäuser, 1458 feet high. The principal heights in the upper county belong to the Thuringian chain, but no remarkable summits rise within the limits of the principality. The highest point is Wurzelberg, 2600 feet high. The surface of the whole is undulating, and the soil fertile, especially in the lower county. This portion, too, enjoys a milder climate than the upper county. Both counties are watered entirely by affluents of the Saale; which river itself forms for a short distance the boundary of the upper county. The Schwarz, Ilm, and Gera, in the upper county; the Wipper and Helbe, in the lower, are the chief rivers; the first two joining the Saale directly, and the others through its affluent, the Unstrut. Agriculture is well attended to; and the chief crops raised are corn, potatoes, and flax, which yield abundantly. The extensive forests also furnish a large amount of timber. Vines are grown in some places; and vegetables and fruit are plentiful. Horses, cattle, sheep, swine, and goats are reared, many of them of good breeds. Game abounds in the country, and fish in the rivers. The mineral riches of the land are great, and many of the inhabitants are employed in mining. Iron is the most important of the minerals; and of it Rudolstadt produces annually about 18,000 cwt., and Sondershausen, 9500 cwt. Salt is also obtained in the former principality, to the amount of 60,000 cwts. yearly. Alum, vitriol, cobalt, marble, gypsum, building-stone, porcelain earth, etc., are found here. The manufactures of the country are not very important. Rudolstadt, however, has one peculiar to itself; that of oils and medicinal substances, chiefly carried on in the village of Oberweissbach. Woollen and linen weaving, brewing, distilling, paper-making, and the preparation of pitch, tar, and lamp-black, employ many people in both principalities. A considerable export trade is carried on, chiefly in salt, timber, corn, and manufactured goods. Education is well attended

to in both principalities: each has numerous elementary schools and a normal seminary; while Rudolstadt has one, and Sondershausen two gymnasiums. The religion of the princes and majority of the people in both states is the Lutheran. In both the constitution is a limited monarchy, the executive power being in the hands of a prince, and the legislative residing in a diet; that for Rudolstadt consisting of sixteen, and that for Sondershausen of fifteen members. The public revenue of the former, according to the budget for 1858, was L.67,149; the expenditure, L.66,578. Of the latter, according to the budget for 1856-59, the revenue was L.80,167; and the expenditure L.79,127. In Sondershausen, in 1856, the debt of the country amounted to L.93,447; and that of the chamber of finance to L.139,056. Both principalities belong to the Germanic confederation; and the contingent furnished by Rudolstadt is 809, that furnished by Sondershausen, 676 men. The history of Schwarzburg is distinguished by no event of any great importance. The most illustrious of the princes was Gunther XXI., who was chosen emperor by a party among the electors, in opposition to Charles IV., in 1347, but who soon after withdrew his pretensions. The Counts, as they were called then, of Schwarzburg, were originally, and for a long time, vassals of Saxony, but in 1699 obtained, for a compensation, their independence from the needy monarch of that country. The two reigning families are descended from the two sons of Gunther XL., who died in 1552; that of Sondershausen from the elder, and that of Rudolstadt from the younger son.

SCHWAZ, a town of the Austrian empire, in the Tyrol, on the right bank of the Inn, sixteen miles E.N.E. of Innsbruck. It has a beautiful Gothic parish church, containing some interesting monuments; also an old Franciscan convent, and a curious tower known by the name of the Mint. Schwaz was formerly celebrated for its silver mines, which were worked in the fifteenth century, in partnership, by the Emperor Maximilian and the Fuggers of Augsburg, and yielded to the latter alone 200,000 florins (about L.22,000) annually. These mines are now exhausted; but iron and copper are still obtained here in abundance. Pop. 4628.

SCHWEDT, a town of Prussia, in the province of Brandenburg and circle of Potsdam, on the left bank of the Oder, 28 miles S.S.W. of Stettin. Its houses are in general well built, and its broad streets are partly lined with chestnut-trees. Here is a palace, with a garden, a riding-house, and a theatre attached to it. This was formerly the residence of the Counts of Brandenburg-Schwedt, a branch of the Brandenburg family that became extinct in 1759. Woollen and linen cloth, tobacco, and starch are made here. Many of the inhabitants are of French origin; for many emigrants settled here after the revocation of the Edict of Nantes. Pop. 7396.

SCHWEIDNITZ, a fortified town of Prussia, in the province of Silesia, on a hill near the left bank of the Weistritz, 29 miles S.W. of Breslau. It is entered by six gates, and has broad regular streets, and two large squares. Most of the houses are well built. The most important buildings are the council-hall and one of the Roman Catholic churches. The latter has a tower 327 feet high, the loftiest in the kingdom; and a beautiful view is obtained from its summit. There are also several other churches, an Ursuline convent, gymnasium, hospital, &c. Here are large barracks, public offices, and a court of law. An active trade is carried on; and there are breweries, distilleries, paper-mills, silk-mills, dye-works, tanneries, and manufactories of woollen and linen fabrics, hosiery, and hats. Schweidnitz is only 11 miles from the Bohemian frontier; and it has, in consequence, been frequently exposed to sieges. Several times during the Thirty Years' War was this its fate; and after being regularly fortified by Frederick

furt
||
Schwytz.

the Great in 1747, it was taken by the Austrians in 1757, but recovered by Prussia in 1759. It was subsequently taken by the French in 1807, and its outer defences were then destroyed. It is now a second-rate fortress. Pop. 14,488.

SCHWEINFURT (anc. *Trajectus Suevorum*), a town of Bavaria, in the circle of Lower Franconia, on the right bank of the Main, 22 miles N.N.E. of Wurzburg. It is an ancient place, still encircled by the old wall and ditch, and entered by two of the old gates. There are here a handsome town-hall, several churches, a gymnasium founded by Gustavus Adolphus, several other schools, and various benevolent institutions. The town has manufactories of woollen and linen goods, hosiery, leather, hardware, tobacco, brandy, &c. Pop. 7800.

SCHWELM, a town of Prussia, in the province of Westphalia, on the Schwelmbach, 35 miles W.S.W. of Arensburg. It has manufactories of linen, woollen, and cotton goods, iron, steel, and hardware, leather, &c.; and some trade in cattle. In the vicinity are medicinal springs. Pop. 4598.

SCHWERIN, a town of Germany, capital of the Grand Duchy of Mecklenburg-Schwerin, on the west side of the lake of Schwerin, 35 miles S.E. of Lubeck. It lies in a beautiful situation, on an irregular piece of ground, almost encircled by the lake and its branches, and by other small sheets of water; and where not surrounded by these, is defended by walls, which are pierced by seven gates. There are an old town and several more modern suburbs. On an island, in the lake of Schwerin, stands the old castle, built by Wallenstein in 1629. It is almost of royal size and magnificence, and has extensive gardens on the other side of the lake. Opposite the castle is a large public place, adorned with a bronze statue of the late grand-duke, Paul Frederick, and lined with the theatre, the grand ducal palace, and the college. The ducal picture gallery, in another part of the town, contains many fine paintings. The ancient cathedral is a fine specimen of the Gothic style, peculiar to the Baltic countries. It contains many interesting monuments. Among the public buildings of Schwerin, are another palace, a town-hall, council-houses for the old and new town respectively, several churches, a mint, and an arsenal. There are numerous schools, a large infirmary, and other benevolent institutions. Some manufactures, chiefly of brandy, vinegar, and tobacco, are carried on here. Pop. 20,723.

SCHWERIN, or **SCHWIERZINA**, a town of Prussia, in the province and 60 miles W.N.W. of Posen, at the confluence of the Obra and the Warthe. It consists of a town proper and a suburb; and besides Protestant and Roman Catholic churches, has also a synagogue. Weaving is extensively carried on here; also brewing and tanning. Pop. 5636.

SCHWIEBUS, a town of Prussia, in the province of Brandenburg, circle and 41 miles E. of Frankfort-on-the-Oder. It stands in a beautiful country, near the Schwemme, and contains a castle and two churches. Important manufactures of cloth are carried on here. Pop. 5228.

SCHWYTZ, one of the cantons of Switzerland, bounded on the N. by those of Zurich and St Gallen, E. by that of Glarus, S. by those of Uri and Unterwalden, and W. by those of Luzern and Zug. Its northern boundary is formed by the Lake of Zurich and the River Linth; its southern boundary by the Lake of Luzern and a branch of the Alps called the Rosstock (between 6000 and 7000 feet high); and its western boundary by the Rigi (5676 feet), the lake of Zug, the Rossberg (5195 feet), and the ridge of Morgarten. On the east the canton has no natural limit. Area, 338 square miles. The whole of the surface is mountainous and rugged, being occupied by ridges of the Alps, and lofty valleys lying between them. The mountains that occupy the centre of the country consist of the western

branches of the lofty Alps of Glarus, which attain in that canton the height of 9528 feet, but gradually diminish towards the west, and nowhere within the limits of Schwytz reach so great an elevation. From the principal chain, stretching westwards near the south of the canton, several branches extend in a northerly direction to the lake of Zurich. In the valleys thus formed rise the upper waters of the Sihl, which flows north and joins the Lemmat below Zurich; and to the south of the main ridge lies the valley of the Muotta, which falls into the Lake of Luzern. The principal mountain-peaks, besides those already mentioned, are Mieseren, 6995 feet; Mythen, 5860 feet; and Rhonc, 4026 feet. Schwytz enjoys a milder climate than many other parts of Switzerland, as its mountains are of less elevation, and nowhere rise above the snow line. But very little of the ground is fit for the plough; and this, like many of the other cantons, is almost entirely a pastoral country, raising on its wide mountain-pastures a large number of cattle and other live stock. The canton is estimated to contain 20,000 horned cattle, about 1000 horses, 6000 sheep, 7000 goats, and 6000 swine. There are some vineyards along the Lake of Zurich; and corn, potatoes, flax, and hemp, are raised in some places, but only to a small extent. The forests of the canton yield an abundant supply of valuable timber. Schwytz is very poor in minerals, and has only some stone-quarries. The manufactures of the country are very insignificant; weaving, cotton-spinning, and lace-making being almost the only branches carried on. The principal articles exported are cattle, horses, and other live stock, butter, cheese, and timber; while corn, wine, brandy, coffee, sugar, and manufactured articles are imported. The inhabitants are of German origin, and belong, with the exception of a very few Protestants, to the Roman Catholic Church. For the education of the people, there is a college at Schwytz, a clerical seminary at Einsiedeln, and numerous elementary schools throughout the country. The constitution is democratical; the legislative power is in the hands of a canton council of eighty-one members, elected by the people in thirteen districts; and the executive power is committed to a government council of seven members—a landamman or president, a vice-president, a treasurer, and four councillors, all appointed by the canton council. The legislative body exists for four years, but one-half of the members retire every two years. The general assembly (*landesgemeinde*) of all the citizens, that formerly met every two years, and had an important share in the legislature, was abolished in 1848, when the present constitution was adopted. The judicial establishment consists of a canton court of thirteen members, with as many supplementary ones, elected by the whole people in the assemblies of each of the six districts; and a criminal court of five judges, appointed by the canton council. Schwytz was one of the three original cantons that formed the confederation in 1308, against the Austrian power; and from its name the modern appellation of the entire country has been derived. See SWITZERLAND. Pop. (1850) 44,168.

SCHWYTZ, the capital of the above canton, is merely a small village in the valley of the Muotta, at the foot of Mythen, a two-peaked mountain, so called from its resemblance to a mitre, 3 miles from the Lake of Luzern and 24 S.S.E. of Zurich. It has a handsome parish church, a council-hall, and an arsenal, in which are the banners captured at Morgarten, as well as those that have been borne by the Schwytz troops on various other occasions. Pop. 5432.

SCIACCA, a seaport town of Sicily, in the province and 30 miles W.N.W. of Girgenti. It stands on the south coast of the island, occupying the slope of a hill, between steep cliffs; and is protected by a citadel, as well as by walls and bastions. The chief buildings in this somewhat mean-looking town are churches, convents, hospitals, and a college. In the vicinity are salt lagoons, sulphur mines, and

Schwytz
||
Sciacca.

Scicli
||
Scilly
Islands.

hot sulphur springs. Some manufactures are carried on; but the chief occupation of the people is the taking and curing of sardines. There is a small harbour, and a good anchorage; but owing to the want of shelter, the trade, which consists chiefly in the export of corn and sardines, is only carried on in summer. Pop. 12,670.

SCICLI, a town of Sicily, in the province of Syracuse, on a river of the same name, 6 miles S.W. of Modica. It has a college and manufactories of cloth and leather. Pop. 9650.

SCIENCE (*Scientia*), in its strictest sense, is a body of organized knowledge, whose phenomena are arranged so as to exhibit the reasons or causes by which they are influenced, in their legitimate connection and interdependence. That science which deals with the succession of reason and consequent, is entitled an *abstract* science; while that which deals with causes and effects is called, for the most part, a *natural* or *physical* science. Those sciences which are supposed to be complete are called *exact* sciences, such as geometry. But the great majority of what are called sciences—that is, all those branches of knowledge in which discovery is possible—hardly deserve the name, being only a bundle of theories or of facts, bound together with more or less exactness, and which a fresh discovery may any day untie. Science not only sees, and sees with certainty, but the distinguishing characteristic of it is, that it *foresees*. Thus it is distinguished from *art*. It is distinguished again from *literature*, in so far as it is its business to discover and apply self-evident principles.

The various sciences will be found under their appropriate heads throughout the work.

SCILLY ISLANDS, a group belonging to England, and included in the county of Cornwall, about 30 miles W.S.W. of Land's End. N. Lat. (of the lighthouse on St Agnes) 49. 53.; W. Lon. 6. 20. The form of the group is nearly circular, about 30 miles round; and the number of islands is very great, but only six of them are inhabited. These are the following:—

	Acres.	Pop. (1851.)	Villages.
St Mary's...	1600	1668	Hugh Town.
Tresco.....	700	416	Dolphin Town.
St Martins.....	550	211	Higher Town.
St Agnes....	350	204	...
Bryher.....	300	118	...
Samson.....	80	10	...

Pop. of the whole (1851)..... 2627

The sea around them is very deep, and they rise out of it with steep and rugged sides; but between the islands the water is much shallower, and some of them are connected by shallows, left entirely dry at low-water. Their geological structure is entirely granitic, with a mixture of quartz, felspar, and mica. The granite is, however, coarse and of little value. The scenery is exceedingly picturesque; and the climate milder and less variable than that of Cornwall; but the soil is in general barren, and, except in a few sheltered spots, no trees grow on the islands. Corn and potatoes are grown on St Mary's, and there is some pasture-ground on others; but the most of the inhabitants are sailors, pilots, or fishermen. It is generally thought that these islands are the Cassiterides or Tin islands of the ancients; but as no trace of that metal is found here, the extremity of the mainland was probably included under that name. They were sometimes used as a place of banishment by the Romans. The sea between them and the mainland is called Lethowsoy, or the Lioness; and if we believe ancient tradition, there was formerly here a tract of slaty rock connecting the islands with the Land's End. This was that "sweet land of Lionnesse," where the knights of the Round Table fell around their lord, King Arthur, and where he was mysteriously carried away from mortal sight.

SCINDE. See SINDH.

SCIO, CHIO, or KHIO (anc. *Chios*), an island belonging to Asiatic Turkey, lying in the Grecian Archipelago, off the coast of Asia Minor, from which it is separated by the Strait of Scio, about 7 miles wide at the narrowest point. N. Lat. (of the capital) 38. 33.; E. Lon. 26. 1. Length from N. to S. 32 miles, greatest breadth 18; area, 508 square miles. The surface is rocky and uneven, being traversed by several limestone ridges, with rich and beautiful valleys between. It is, indeed, one of the most beautiful of all the Grecian islands; and is abundantly watered by many springs and rivulets, so as to preserve a constant verdure. As only a small portion of the soil is fit for the plough, corn is not raised to any great extent; but the ground is suitable to various other valuable crops. The wine of Chios was one of the most esteemed beverages of the ancient world, and is still held in some repute. In modern times, however, the chief production of the island has been gum mastic, obtained from the juice of a certain shrub. Figs, oranges, lemons, and other fruits, are also raised; and among its other productions are silk, cotton, oil, and wool. The only mineral of importance is marble, of which there is a quarry near the chief town. The chief articles imported into the island are corn, iron, tin, earthenware, and colonial produce. A considerable navigation is carried on, both in the foreign and coasting trade. The port, however, is so choked up with mud as to be difficult and dangerous of entrance. Hence few European vessels anchor here. Scio is connected by ancient tradition with the father of Greek poetry, "the blind old man of Scio's rocky isle;" it was one of the seven places that contended for the honour of having given him birth. Apart from this doubtful renown, the history of the island, both in ancient and modern times, has much interest. The original inhabitants are believed to have been Pelasgians, who came, according to one tradition, from Thessaly. Subsequently Ionian settlers established themselves here, but did not entirely expel the previous occupants. Chios thus became a member of the Ionian confederation of twelve states on the Asiatic islands and coast. Its insular position protected it against the Lydian, and for a time against the Persian power. But in the Ionian revolt, the Chians lent their assistance to their fellow-countrymen by furnishing ships to the fleet, which was totally defeated by the Persians off Miletus, 494 B.C. The conquerors in consequence landed on the island, and ravaged it with fire and sword. The battle of Mycale, in 479, liberated Chios from the Persian yoke, but only to become a dependency of Athens. To this power it remained faithful, till after the outbreak of the Peloponnesian war; but as that disastrous contest proceeded, and the fortune of war began to prove adverse to Athens, the Chians attempted to assert their liberty. They suffered several defeats from the Athenians, who laid waste the island, but could not conquer the capital. At a later period Chios was again subject to Athens, and again revolted, and seems to have maintained its independence for some time. It gave assistance to the Romans in their war with Antiochus, 190 B.C.; and afterwards, when allied with Mithridates, that monarch, suspecting the people of a bearing towards the Romans, sent a lieutenant, who carried the inhabitants away from the island, 86 B.C. They were restored by the Romans; and, in consideration of this calamity, the island was made a free state and an ally of Rome. Under the Roman empire the history of Chios presents no event of importance; but in subsequent times the place appears as the scene of as great calamities as before. Early in the fourteenth century, the Turks conquered the capital, and perpetrated a general massacre of its inhabitants; but from 1346 to 1566 Scio was held by the Genoese. In the latter year it was conquered by Solymán the Magnificent; and since that time, with the exception of a short period

Scinde
||
Scio.

Scioppius. when the Venetians possessed it, the island has belonged to the Ottoman empire. In 1822, during the Greek insurrection, a number of Samians landed in Scio, and persuaded or forced its peaceful inhabitants to rise against the Turks. They did not succeed in mastering the castle; and soon an army was landed from Asia, who renewed the ancient calamities of the island. The plunder and massacre that ensued were so unsparring, that in a short time only 2000 Christians were left out of a population of 110,000. Many traces of this disaster may yet be seen in Scio, but it is beginning to recover from its desolation, and the population is estimated at 62,000. The capital, called Khio or Castro, occupies the site of the ancient Chios, near the middle of the east coast. It is generally well built, in the Italian style, and has a castle and a harbour. Some remains of ancient buildings are still to be seen. Previous to 1822 the population was 30,000; it is now not half that number.

SCIOPIUS, GASPAR, a learned German writer of the seventeenth century, was born at Neumark, in the Upper Palatinate, on the 27th of May 1576. He studied at the university with so much success, that at the age of sixteen he became an author, and published books, says Ferrari, which deserve to be admired by old men. But his disposition did not correspond with his genius. Naturally passionate and malevolent, he assaulted without mercy the characters of eminent men. He abjured the system of the Protestants, and became a Roman Catholic about the year 1599; but his character remained the same. He possessed all those qualities which fitted him for making a distinguished figure in the literary world—imagination, memory, profound learning, and invincible impudence. He was familiar with the terms of reproach in most languages. He was entirely ignorant of the manners of the world. He neither showed respect to his superiors nor did he behave with decency to his equals. He was possessed with a frenzy of an uncommon kind, being a perfect firebrand, scattering around him, as if for his amusement, the most atrocious calumnies. Joseph Scaliger, above all others, was the object of his satire. That learned man, having drawn up the history of his own family, and attempted to deduce its genealogy from princes, was severely attacked by Scioppius, who ridiculed his high pretensions. Scaliger, in his turn, wrote a book entitled the *Life and Parentage of Gaspar Scioppius*, in which he informs us that the father of Scioppius had been successively a grave-digger, a journeyman stationer, a hawker, a soldier, a miller, and a brewer of beer! These statements almost set Scioppius mad. He collected all the calumnies that had been thrown out against Scaliger, and formed them into a huge volume, to crush him at once. He treated James I., king of England, with great contempt, in his *Ecclesiasticus* and in his *Collyrium Regium Britanniae Regi* (that is, An Eye-salve for his Britannic Majesty). In one of his works he had the audacity to abuse Henry IV. of France in a most scurrilous manner, on which account his book was burned at Paris. He was hung in effigy in a farce which was represented before the king of England, but he gloried in his dishonour. Provoked with his insolence to their sovereign, the servants of the English ambassador assaulted him at Madrid and corrected him severely, but he boasted of the wounds he had received. He published more than thirty defamatory libels against the Jesuits; and what is surprising, in the place where he declaims with most virulence against that society, he subscribes his own name with expressions of devotion: "I, Gaspar Scioppius, already on the brink of the grave, and ready to appear before the tribunal of Jesus Christ, to give an account of my works." Towards the end of his life he employed himself in studying the Apocalypse, and affirmed that he had found the key to that mysterious book. He sent some of his expositions to

Cardinal Mazarin, but the cardinal did not find it convenient to read them.

Ferrari tells us that, during the last fourteen years of his life, Scioppius shut himself up in a small apartment, where he devoted himself solely to study. The same writer acquaints us that he could repeat the Scriptures almost entirely by heart; but his good qualities were eclipsed by his vices. For his love of slander, and the furious assaults which he made upon the most eminent men, he was called the Cerberus of literature. He accuses even Cicero of barbarisms and improprieties. He died on the 19th of November 1649, at the age of seventy-four, at Padua, the only retreat which remained to him from the multitude of enemies whom he had created. He was a man of prodigious learning, and of great acuteness. He had no equal in his knowledge of the Latin language, and he might have attained as great a reputation as his opponent, Joseph Scaliger, had his temper been a little better, and had he indulged less frequently in satire and general intolerance. He edited and wrote notes to a great many authors. One hundred and four works are ascribed to him, which discover great genius and learning. Many of his works were published under assumed names. The chief of his writings are *Verisimilium Libri* iv. 1596, in 8vo; *Commentarius de Arte Critica*, 1661, in 8vo; *De sua ad Catholicos Migratione*, 1660, in 8vo; *Notationes Criticae in Phaedrum, in Præpeia*, Patavi, 1664, in 8vo; *Suspectarum Sectionum Libri* v. 1664, in 8vo; *Classicum Belli Sacri*, 1619, in 4to; *Collyrium Regium*, 1611, in 8vo; *Grammatica Philosophica*, 1644, in 8vo; *Relatio ad Reges et Principes de Stratagematibus Societatis Jesu*, 1641, in 12mo.

SCIPIO (Lat. *a staff*), the name of an illustrious patrician family of Rome, of the gens Cornelia. It rose to great power in the Roman state, and to this family more than to any other Rome was indebted for her empire over the world. Of the thirty-six names usually given in connection with that distinguished house, unquestionably the most illustrious were Publius Cornelius Scipio Africanus Major, and Publius Cornelius Scipio Æmilianus Africanus Minor.

SCIPIO AFRICANUS MAJOR, *Publius Cornelius*, the son of Publius Cornelius Scipio, who fell in Spain, was probably the greatest man in Rome after Julius Cæsar. He was born B.C. 234, since he was twenty-four years of age when appointed to the command in Spain, B.C. 210. From his early youth he displayed an uncommon reverence for the worship of the gods; and his quiet but deep enthusiasm burned in him like a flame. Before engaging in any business he first went to the Capitol, and there, in the high retirement of his own soul, held converse with the unseen powers, who gave or withheld their approval of the project which he had in view. Those Romans who still held on by any vestige of faith in the old Roman religion, entertained his assertions, and stood in awe of his person. There germinated in this man, despite the scepticism of Polybius, a deep and strong faith in the permanence of religious ideas, and in the constancy of religious impressions, which in other circumstances would have led him into the wilderness as an ascetic, or would have endowed him with the rapt earnestness of a mystic. Scipio was born a hero, and not an impostor. The large enthusiasm of his nature found vent in rude military life, where, if it found much to check the vigour of its growth, met likewise with much which it could assimilate. By presenting to the vulgar minds of the soldiery a picture of rapt devotion and yet of stern command, he gained an influence over them which was quite extraordinary because quite irresistible. In the more immediate relations of generalship, what could resist the energy of that arm which, in its every blow, dealt desolation and death to the enemies of Rome and of the Roman gods? When this religious enthusiasm seized hold not only of the feel-

Scipio.

Scipio.

ings of a single man or his immediate attendants, but which animated an entire army with its assuring influence, where was the Carthaginian who could stand long before its power? where the Hispanian who would not speedily bow before it as before the march of doom?

At the age of seventeen he fought at the Ticinus (in 218 B.C.), and is there reported to have saved his father's life. As a tribune, he fought and survived the fatal battle of Cannæ, was made joint commander of the remains of the army with Appius Claudius at the age of nineteen, and by his youthful heroism brought light to his bewildered countrymen, and induced them to forego the silly project of resigning Italy in despair. He was chosen ædile ere he was twenty-four. He displayed his arrogant temper to the hesitating tribunes on that occasion in these words—"If all the Quirites wish to make me ædile, I am old enough." He lost his father and uncle in Spain in 211 B.C., and ere the year was out, when, in default of a more experienced general, he presented himself to the Roman people to command their army in Spain, he was received first of all with silent wonder, and lastly, gaining confidence by the picture of stern resolution presented to them in this young soldier, they chose him with shouts of acclamation. He arrived in Spain in the summer of 210 B.C. The whole country south of the Iberus was in the hands of the enemy. Scipio at once resolved to strike a deadly blow at the head of the Carthaginian power, by attacking New Carthage. His project was crowned with success. In the conquered city he found a great abundance of arms, corn, and other necessaries. He retired to Tarraco, where he remained during the winter. Here, so great was the general enthusiasm of the people by the mildness, the courtesy, and the energy of the young Roman, that the Spanish tribes not only came over to his cause, but wished to make him their king. Next year he attacked Hasdrubal, in the valley of the Guadalquivir, and gained an almost incredible victory. It is said by the Roman writers that no less than 22,000 men were taken prisoners, and 8000 slain. In 207 B.C. Scipio gained, by a decisive victory, nearly the whole of Spain. He sheathed his sword, and trusted to the influence of humanity to win the rude inhabitants. They gathered round him, eager to kiss his garment, and all the native chiefs flocked in to offer their allegiance to omnipotent Rome. With the design of securing the co-operation of some of the native princes of Africa, Scipio crossed over into that country, accompanied by two quinquiremes. There he met his old foe, Hasdrubal, the son of Gisco, who had crossed over from Spain upon a similar errand. The Carthaginian, aided by the charms of a fair daughter, seems on this occasion to have outwitted the Roman commander. Scyphax, king of Numidia, received Sophonisba in marriage, and thus cemented the Carthaginian interest to his own. On his return to Spain, Scipio chastised severely the town of Illturgi for having led on a revolt among his soldiers. He was seized with a severe illness. During the progress of his disease, 8000 of his own men broke out into open revolt. He suddenly rallied, and by his wonted dexterity at once allayed the fury of the soldiery. Scipio, whose presence was now no longer needed, returned to Rome in 206 B.C., leaving the proconsuls masters of the army and of Spain. He had hardly returned to Rome when he became a candidate for the consulship, and had the honour to be chosen, though considerably under the legal age. It now became apparent that if Hannibal was to be removed at all from Italy, it should be performed by a diversion against the Carthaginians on their own soil. No man was capable of effecting this save the youthful hero who had first asserted the prowess of the Roman arms in Spain. This Scipio clearly foresaw; but the older senators, and especially Q. Fabius Maximus, who was prompted by a meagre jealousy,

Scipio.

sought stealthily to thwart. After their various wiles had been burst through, this splendid youth, with his passion for Greek art and Greek literature, showed his suspicious rivals that he knew as well how to train an army as how to conduct it in the field. Commissioners of inquiry had been summoned from Rome to the head-quarters of the army in Sicily, but the enthusiasm of the volunteers and the skill of the commander astounded these officials, and they went back only to tell the senate that they had commanded Scipio to march against Carthage. Sailing from Lilybæum in 204 B.C., he landed near Ætica with a force variously estimated at 12,200 and at 35,000 men. Masinissa, whose friendship he had made in Spain, now stood him in good stead. With the assistance of this prince, Scipio almost annihilated the joint forces of Hasdrubal and Scyphax. (See MASINISSA.) These disasters induced the Carthaginians to recall Hannibal and Mago from Italy. An armistice was accordingly struck, and the Roman army lay impatient before the walls of Carthage. The presence of their renowned general gave confidence to the Carthaginians, but Hannibal knew too well the army and the general he had to contend with, to be rash in his projects. Both generals, in truth, were anxious for a solid peace, but a solid peace on advantageous terms was what Scipio was quite unwilling to grant, and short of which the pride of Hannibal would not deign to stoop. The bloody battle of Naraga, near Zama, fought on the 19th of October 202 B.C., settled the contest in favour of the Romans, and Scipio returned to Rome in triumph 201 B.C. The populace manifested extraordinary enthusiasm, and sought to gratify it by quite extraordinary means. They bestowed upon him the surname of *Africanus*, and wished to make him consul and dictator for life. They wished to erect his statue in the comitia. They would set it up in the rostra and the curia, and even went so far as to wish his enthronement in the Capitol. Scipio prudently declined those invidious honours; and to shun the suspicion of the senate, he withdrew into dignified retirement. Coming once more before the public, he was chosen censor and consul the second time. In 190 B.C. the censors re-elected him *princeps senatus*, and during the same year he chose to accompany his brother Lucius to Greece, to serve under him as *legatus*. Returning to Rome in 189 B.C., on the conclusion of the war with Antiochus, the mean jealousy of the senate gave him fresh cause for alarm. The glory of the victory of Zama had now grown dim, the pride of the great general probably did not abate, and the Roman senate, with their paltry suspicions, could not brook the infringement of a jot of their dignity. They opened a prosecution against Scipio's brother, Lucius, but really directed against Africanus himself. This being successful, the enemies of the Scipios were emboldened to charge the great African. At his trial he descanted much on his signal services to the commonwealth, but did not deign to notice the charges brought against him by his foes. Night came, and the great culprit still continued to speak. The trial was adjourned till next day, and Africanus, on being summoned to appear, proudly reminded his judges and the people of Rome that this day was the anniversary of the battle of Zama. He adjured them in the same haughty terms to follow him to the Capitol, and return thanks to the immortal gods for the safety of Rome, and to pray them to grant in time coming other citizens like Scipio Africanus. The crowded assembly listened with breathless attention: he smote a chord which vibrated through every Roman heart: their veneration for Scipio returned; and he was followed to the Capitol with shouts which shook the stones of Rome. The haughty soldier quitted Rome never to return. He withdrew to Liternum, where he passed the remainder of his days in the peaceful cultivation of his estate. The year of his death is variously given by Polybius and Rutilius as 183 B.C., the same year as his great rival, Hannibal. By Livy and Cicero

Scipio. it is ascribed to 185 B.C., and by Valerius of Antium to 187 B.C. In compliance with his own command, his bones were buried at Liternum, where his tomb was shown in the time of Livy. Thus died one of the greatest men and most distinguished generals which Rome had known; and beside the pedestal occupied by Hannibal in the Temple of Fame stands the statue of his conqueror, Scipio Africanus.

SCIPIO ÆMILIANUS AFRICANUS MINOR, *Publius Cornelius*, was the son of Æmilius Paulus, conqueror of Macedonia, and was adopted by Scipio, son of the elder Africanus, whose mother was a sister of L. Æmilius Paulus. He was born in 185 B.C., and while still a youth he accompanied his father to Greece, and fought under him at the battle of Pydna, B.C. 168. It was in Greece, most probably, he became acquainted with the historian Polybius, who, on coming to Rome, directed his literary studies, and introduced him to the art and the literature of Greece. Polybius accompanied him in all his campaigns, and disclosed to him during the leisure hours of his military duties, the treasures of Grecian thought and the wealth of Grecian learning. Nor did Scipio the younger neglect the literature or the manners of Rome, while he eagerly pursued those of her great eastern rival. He was a friend of the poets Lucilius and Terence; and his affection for the younger Laelius was as remarkable as that of Africanus for the elder Laelius, and has been immortalized by Cicero in his *Laelius sive de Amicitia*. Like the elder Scipio, he cultivated Greek letters, and understood the elegancies of Greek taste, without setting aside the stern Roman virtues, or emasculating his mind by the warm blandishments of a more refined civilization. The younger Scipio began his public career in 151 B.C., by coming forward when it was quite the fashion to stand back, and offering himself to serve in dreaded Spain in whatever capacity the consuls might choose to employ him. He was appointed military tribune, under the consulship of Lucullus, and gave signal proofs of his personal courage during the adventures of this Spanish campaign. He slew in single strife a Spanish giant of great strength, and was the first to mount the walls at the storming of Intercatia. His courage and his integrity reminded the barbarians of him whose name he bore, and he awakened an enthusiasm in the breasts of the rude savages, equalled only by that paid to his grandfather Africanus.

On the breaking out of the third Punic War in 149 B.C., Scipio was called to Africa, which he had already visited, under Lucullus, for a supply of elephants. Here he repaired the blunders of the consul Manilius, gained the confidence of Masinissa, and what he probably valued more than any of the more noisy demonstrations, the "stern" Cato said of him, in the words of Homer (Od. x., 495), "He alone has wisdom, the rest are empty shadows." On Scipio's withdrawal from Africa, when Piso took the command, he was followed to Rome by the wishes of the soldiery, that he might become their commander. To this dignity he was raised sooner perhaps than he expected. In 147 B.C. he was chosen consul, though not yet of the legal age, and was assigned Africa, the most difficult province of Rome, to govern. The details of the third Punic War will be found in the article ROMAN HISTORY, where will be found recorded the bloody capture of the splendid African city. The Carthaginians defended their city till the spring of 146 B.C., when they could no longer withstand the stern energy of the Roman legions. They advanced with thundering tramp, and at every street, and at every house of Carthage, they found the bloodiest work to do. The sight moved the Roman general to tears, and he is said to have given scope to his feelings in the almost prophetic words of Homer, recorded in the well-known lines of the Iliad (vi. 448)—

Ἔσσεσθαι ἡμᾶς, ὅτ' ἂν ποτ' ἐλῶλη Ἰλίου ἱερή,
καὶ Πρίστμος καὶ λαὸς ἑμμελίῳ Πριάμοιο.

VOL. XIX.

The victor returned to Rome, where he was welcomed with a splendid triumph, and he now won the surname of *Africanus*, which he had only before received by inheritance from the conqueror of Hannibal. In no long time the ungrateful Romans had him brought to his trial before the tribune of the plebs, on the charge of *majestas*, or of contemning the sovereignty of the people. Scipio was acquitted, and the speech delivered by him on this occasion was long considered a masterpiece. He strove to check the Roman appetite for foreign conquest, and showed a high contempt for the pomp and luxury indulged in by his contemporaries. He was chosen consul in 134 B.C., and was assigned the province of Spain, which had long been considered invincible by any but a Scipio. After spending some time in remodelling the discipline of the army, he laid siege to Numantia, which displayed a most heroic resistance. (See NUMANTIA.) The taking of this town gained for him the surname of *Numantinus*. During his absence in Spain, his brother-in-law, Tiberius Gracchus, was suddenly put to death. Scipio did not, however, sympathise with his reforms, and is said to have exclaimed, on hearing of his death, in the words of Homer (Od. i., 47), "So perish all who do the like again." Scipio did not disguise his sentiments even on his return to Rome, and "down with the tyrant," was soon heard from the fickle mob who not long before had hailed him as the liberator of Rome. This flame was fanned by C. Papirius Carbo, the tribune, who could not tolerate the shadow of his presence, with his thirst for Greek letters and for Greek philosophy, and what was still more offensive, by his fondness for public display. Scipio was in truth a sort of Roman Tory, strongly addicted to letters, which he cultivated with great success, much given to military display, which bordered on parade, and earnestly opposed to nearly all popular measures. He paid too dear a price for his peculiarities. Returning home from the senate-house, he retired to his study, to compose a speech in his own defence against the following day. Next morning the cry went through Rome that Scipio Africanus Numantinus was dead, B.C. 129. The general opinion was that he was murdered, but by whose hand never was known. Popular suspicion generally rested on the tribune, Papirius Carbo; and he is expressly alluded to as the murderer by Cicero.

The few fragments of the speeches of Scipio the younger have been collected by Meyer in *Orat. Roman. Fragm.* pp. 176–193. His character has been drawn in very pleasing colours by Cicero, in his *Republica*. His life and death have been noticed with ability by Nitzsch, Scheu, Gerlach, and Zimmerman.

A good account of the Scipio family is given in the *Real-Encyclopadie der classischen Alterthumswissenschaft*. The Scipios, as was usual among Roman families of distinction, possessed a burial-place used for family purposes. This tomb was discovered in 1780, near the Porta Capena, and adds a very interesting detail to the collection of discoveries relating to the republican period of Rome. A full account of the tomb is given by Visconti in his *Monumenti degli Scipioni*, and the inscriptions are given by Orelli.

SCLAVONIA. See SLAVONIA.

SCONE, a village of Scotland, in the county and 2 miles N.E. of Perth, on the left bank of the Tay. It is neatly built, and inhabited chiefly by weavers. Scone palace, the seat of the Earl of Mansfield, is a modern castellated building, on the site of the ancient royal palace, where the Scottish monarchs were crowned. The celebrated stone, on which the ceremony used to be performed, is now in Westminster Abbey, and forms part of the coronation chair. Of the old abbey of Scone only a single aisle now remains. Pop. of village, 1439; of parish, 2381.

SCOPAS, a distinguished sculptor of the later Attic school, was a native of Paros, where he was born during

Sclavonia

Scopas.

Score.

the first half of the fourth century B.C. Pliny places him with Polycleitus, Phradmon, Myron, Pythagoras, and Perelius, 420 B.C., but this cannot possibly be accurate. (See Sillig. *Cat. Art.*) He was probably somewhat older than Praxiteles, with whom he left the fruits of his handiwork on the Mausoleum at Halicarnassus. The period during which he flourished must have been from 395 B.C. to 350 B.C. Nothing is known with certainty regarding the life of the artist, except what one can gather from the fragmentary remains of his works still extant. He was not only a sculptor, he was likewise an architect and statuary. His chief performances are the Niobe group, the Budrum marbles, and various statues chiefly of the gods of Greece. The architectural works of Scopas are very justly celebrated. He built the temple of Athena Alea, at Tegea, in Arcadia, which was accounted the most magnificent building in the Peloponnesus. Scopas likewise decorated the building with the products of his chisel, of which the most celebrated designs were the chase of the Calydonian boar and the battle of Telephus with Achilles. (Pausanias, vii. 45.) This artist was likewise supposed to be the architect of the temple of Artemis, but the critical investigations of Sillig have thrown much doubt on this hypothesis. There is more certainty as to the part taken by Scopas in the decoration of the famed sepulchre of the king of Caria at Halicarnassus, or the modern *Budrum*. The eastern front seems to have been executed by this artist, and the other portions by different workmen. (See *MAUSOLEUM*.) He executed statues from the mythology of Aprodite, of Dionysius, of Apollo, and of Artemis. But the most esteemed work ascribed to Scopas is the celebrated group of the destruction of the sons and daughters of Niobe. It is a disputed point whether we owe this glorious production of Greek art to the genius of Scopas or of Praxiteles. Winckelmann ascribed it to Scopas, and perhaps the most celebrated description of it is by the late German philosopher, Schelling. Besides the statues to other divinities, Scopas is said to have executed a famous group of Achilles conducted to the island of Leuce by the divinities of the sea. Pliny, on whose authority this work is cited, esteemed it the best of all the productions of Scopas. Very few facts can be ascertained entirely beyond dispute regarding this artist's labours.

SCORE, or **PARTITION**, in *MUSIC*. Either of these terms means that written or printed arrangement of different parts for voices or instruments, or for both, by which the structure of any piece of music, consisting of a number of such parts, is brought successively under the eye, measure after measure, so as to enable the student of composition to study the work, or the conductor of an orchestra to accompany the whole suitably on the pianoforte or organ, or instantly to perceive and correct errors in the performance, especially during rehearsals. In a score or partition, all the staves required in any given page for the different parts should be marked with their proper clefs, &c., and, on the left margin, with the names of the different voices or instruments, and then braced together at the left side, while at every bar of the measure a straight line is drawn down the page, from the top of the highest stave to the bottom of the lowest. For the sake of perspicuity, in every partition the same number of staves ought to be used from beginning to end on every page, even where many bars of rests occur in this or that part; and also the clefs, &c., ought to be marked on every page, as well as the names of the different voices or instruments. The general neglect of these simple precautions renders many partitions extremely confused and perplexing to their readers. In the article *MUSIC*, we have used the word *partition* in preference to the word *score*, for various reasons; and especially as we had already the word *partition* used in the sixteenth century by an English writer of

eminent musical authority, in the very sense in which we employ it. Thomas Morley, in his *Plaine and easie Introduction to Practicall Musicke*, edition of 1597, page 34, has stamped the word *partition* as an English musical term. He says, "and to the ende that you may the more easily understand the contriving of the parts, and their proportion one to another, I have set it downe in *partition*." (G. F. G.)

SCORESBY, WILLIAM, D.D., an eminent explorer of the Arctic regions, the third child of William and L. Mary Scoresby, was born at Cropton, near Pickering, in the county of York, on the 5th of October 1789. He was a delicate, bashful child; was early impressed with a sacred regard to truth, and of the importance of religious duties, qualities which remained with him during life. In 1802 he was for several months sent to school under the care of Mr Stock, in the neighbourhood of Blackwall, where he was instructed in the elements of English grammar, writing, and arithmetic; but the effect of intense application was too much for a delicate constitution. His studies commenced at five in the morning, and continued until the same hour in the evening, with the usual intervals for meals; but besides these lessons, he wrote various exercises at home, and attended occasional lectures of his master on some branches of science in the evenings. There, too, he obtained his first lessons in theoretic navigation.

His inclination for a seaman's life led him, in 1800, to conceal himself in his father's ship, setting out on a Greenland voyage, until the pilot-boat had left the vessel. He was therefore equipped as an apprentice, and adopted the life of a seaman, in which he made such proficiency that, when sixteen years of age, he was advanced to the office of chief mate of the ship. During the intervals of his different Greenland voyages, he studied assiduously, at the school of Mr Routh in Whitby, algebra, geometry, and the application of mathematics to navigation and marine surveying. In these branches he soon found the explanations of his masters (from their want of practical application) neither quite satisfactory nor always intelligible, and his full attainment of these branches was the result of his private studies. He stated that he might have attained some proficiency in Latin from his able master had he had taste for more than the mere elements of that language.

In the winter of 1806 he repaired to Edinburgh, and attended some of the classes in the university; but his profession again recalled him to Whitby in March 1807.

On returning from the Greenland voyage in 1807, he volunteered his services to assist in bringing the Danish fleet to Britain, and for this purpose he sailed from Leith to Copenhagen. He was thus employed three months; for this the government remuneration was the trifling sum of L.11, 19s. 2d., including bounty, wages, and travelling expenses! His own account of this incident in his life is thus stated:—"Thus ended an adventurous and trying voyage—a voyage in which I voluntarily submitted to every service and privation of the commonest sailor, though from being furnished with introductory letters from naval officers of some consideration, I might probably have fared better had I made use of them; but I wished to take my chance in the ordinary way, that I might have better opportunity, by personal experience, of learning the discipline of the navy, and the duties expected from a seaman in that service." In that same year he was introduced to Sir Joseph Banks, of whom he soon became a frequent correspondent.

In 1809 Scoresby made his first assay as harpooner in his father's ship, while still acting as chief mate. On his return he again became a student in the University of Edinburgh, and attended the course of natural history of Professor Jameson, with whom he became intimately

Scoresby.

Scoresby. acquainted; and he furnished valuable papers to the Wernerian society on the Greenland ice, the meteorology of those regions, and on the Greenland whale.

On the 5th of October 1810, his twenty-first birthday, Mr Scoresby was appointed to the command of the *Resolution*, Greenlandman, and sailed in her on the following March. His success in this voyage was remarkable, for he captured 30 whales, which yielded 220 tons of oil, the largest quantity that had then been brought to Whitby by a single vessel. The influence of his religious education, and his mature reflections on this important subject now became conspicuous. He did all in his power to promote religious feeling among his crew, called them regularly on Sunday to Divine service, and abstained from pursuing the whale on that day.

On the 25th of September 1811, Mr Scoresby married Miss Mary Eliza Lockwood. Their first child, William, was born in April 1812. In this year he resigned the command of the *Resolution*, and was appointed to the *Esk* of Whitby.

In 1813 he made his first series of experiments on the temperature of the ocean at considerable depths, of which an interesting account is given in his capital work, *The Arctic Regions*. In this voyage, as on many other occasions, his judgment and courage were conspicuously displayed, and eminently contributed to the safety of the vessel. For several years his voyages were prosperous; but in 1816 he made a disastrous one, in which the vessel was nearly lost. This disaster induced him to think of retiring from his nautical occupation, but the bankruptcy of a friend, to whom he had lent a large part of his earnings, made him give up the idea, and to trust to Providence for his future success. The equanimity with which he bore this disappointment raised him higher in the estimation of his friends than even his scientific attainments, which had obtained the approbation of the learned.

His letters to Sir Joseph Banks in 1817 had described the vast disruption of the Arctic ices which had recently taken place; and this induced Sir Joseph to memorialize the government on the prosecution of Arctic discovery, in consequence of which that series of expeditions to the North commenced, which distinguished the early half of this century. From Scoresby the admiralty obtained much important information as to Arctic navigation. The proposal made to him it was impossible for him to accept, viz., to go out as pilot in one of the ships, when he was perfectly aware that, in the event of success, the merit would be ascribed to the superior officer, and if unsuccessful, the failure would be imputed to him. He therefore declined the offer, while he expressed his willingness to take the command of the smallest vessel the admiralty would entrust to him, and do his best to bring the expedition to a successful termination. The etiquette of the naval service was considered as an objection, although, when Cooke was sent on his first voyage, he had never served in the British navy.

In 1818 Mr Scoresby became his father's partner in the Greenland ship *Fame*, which was fitted out at Liverpool, where the writer of this memoir first became acquainted with him, and admired the extent of his acquirements, his happy mode of communicating information, and his extreme modesty. During the voyage of this year Scoresby repeated his experiments on the temperature at great depths of the ocean, and made a curious set of experiments on the effect of the pressure of a great column of water on different kinds of wood, in which the most buoyant of them became so heavy as to sink in water. During this year his second son, Frederick R. H. Scoresby, was born. Both his sons died before their father.

The year 1819 was occupied in superintending the building of his new ship the *Baffin*, at Liverpool, and in the com-

Scoresby. position of his admirable work, *The Arctic Regions*, which contains much original information on Polar countries and seas, detailed in a lucid and well-written narrative. It was printed in two octavo volumes of about 500 pages each, illustrated by maps, drawings of animals, &c. His account of the *mysticetus* corrected the common error that the whale in *blowing* throws out torrents of water, whereas it is vapour condensed by the cold air that has been mistaken for a column of water; and his figures of that whale were the first accurate representations of that animal. In fact, all former representations of it were caricatures of nature.

In the year of its publication appeared a good analysis of Scoresby's works, drawn up by M.M. Rossily and Rossel, addressed to Baron Portal, the French minister of marine, in which the book is much commended and proposed for translation, as important to the commerce of France. The first chapter of volume I. gives a succinct history of Arctic voyages; the second gives hydrographic descriptions of those regions; the third is a survey of the Greenland seas; the fourth is dedicated to the polar ices and seas frequented by Arctic whale-fishers; the fifth is a most original account of the climate, temperature, and general atmospherology of those regions, the result of twelve consecutive voyages; the sixth treats of the zoology of the Arctic seas, on which it throws much important light. The appendix to this volume contains his meteorological journal for twelve years in those seas. The second volume is wholly dedicated to the whale-fishery, and contains much important information not elsewhere to be found. The French critics pronounce the work to be "a perfect and complete whole."

In 1820 he made his first and a successful voyage to Greenland in the *Baffin*, which was found to answer his expectations as to her construction in every respect.

In the voyage of 1821, the philanthropic engineer, Captain Manby, sailed with him for the purpose of trying the efficacy of a new method of capturing the whale, devised by the former, but it did not answer his hopes. In the end of this year Scoresby had another communication with the admiralty respecting the grant of money to any whaler who should discover a new station for the successful prosecution of this important branch of industry, as the usual stations had been deserted by the whale, and the risk of loss in such adventures was becoming more and more imminent, but his representations were unsuccessful.

In the voyage of 1822, Scoresby not only made a very successful whaling voyage, but visited the long-lost eastern coast of Greenland, which he surveyed and beautifully laid down for about 800 miles, between Gale Hamke's Land in Lat. 75. N. and Lat. 69.10. N. He landed at many points of this coast, entered several of its inlets, gave designations to this hitherto nameless region, and carried home specimens of the rocks and plants found where he landed. In a few places he found traces of Esquimaux habitations, even in high latitudes; but the supposed remains of considerable buildings and towns of the Icelandic settlers on this desolate coast, which have been sometimes mentioned, Scoresby has shown to be illusions produced by the remarkable refractions of the ice-bound confines of this land, which so often simulate the creations of human industry. In this voyage he penetrated to within 566 geographic miles of the North Pole, as detailed in the first and second chapters of his *Journal of a Voyage to the Northern Whale Fishery*, where he found the temperature then so low as within 2° or 3° of zero, whence he concludes against the probability of an open sea around the Pole, as imagined by some; the third chapter details his proceedings when in sight of the east coast of Greenland; the fourth gives the commencement of the survey of that coast, which is continued in the succeeding chapters, that contain also most valuable observations on the wonderful atmospheric refraction.

Scoresby. tions there seen. The instruments employed in this survey were sextants, Kater's Azimuth compass, and chronometers. He took more than 500 bearings from 50 stations, besides 200 or 300 more for correcting the variation and deviations of his compasses. Four-fifths of these were obtained by intersecting bearings, and one-fifth from single bearings and estimated distances. The appendix contains a list of the rocks and plants he collected, the animals he saw, the latitudes and longitudes of the points of the coast, with speculations on the inhabitants, whose habitations he discovered in various parts of that desolate region. He supposed that there are recent indications of arts beyond those of the Esquimaux, indicating a mixed race as existing in that part of Greenland.

During his voyage of 1822 Mr Scoresby lost his wife; and soon after he determined to give up his nautical pursuits, and resolved to prepare himself for the ministry in the Established Church of England. With characteristic determination he proceeded to supply the defects of his early education in classical learning, and with indomitable perseverance he applied to the study of Latin and Greek. At the suggestion of his friend, Archdeacon Wrangham, he boarded for some time in the house of a clergyman, who directed his classical studies, as a preparation for the University of Cambridge. His acquirements in mathematics and in theology were even already of considerable extent, but he neglected not those important branches while he pursued his classical studies. He became a student of Queen's College, where in due time he obtained the degree of A.M., and had subsequently the honour of D.D. conferred on him. He was admitted into ecclesiastical orders, and soon after was appointed clergyman to the Mariners' Church in Liverpool, which was a large ship, fitted up commodiously for a considerable congregation; and his judicious ministry among the seamen was much appreciated.

In 1828 he married Miss Elizabeth Fitzgerald, an amiable lady of a highly respectable Irish family. Besides his clerical duties, Scoresby was occupied with scientific pursuits, especially in magnetism, which he had long very successfully prosecuted; and he made numerous experiments on the mode of imparting intense magnetic power to steel bars by percussion, when they were placed in the position of the magnetic dip. The percussion might be communicated either by a hammer or by an electric shock. In fact, he had, in the voyage of 1822, discovered that by hammering the steel bar in a vertical position, while it rested on a bar of iron, or better on a magnet of soft steel, he could impart most intense magnetism; and thus, in the event of a ship's compass having its magnetism destroyed by lightning, it could be restored without any complex apparatus. In this way he made magnets of immense power. He also investigated the connection between magnetism and galvanic electricity. On this latter subject a joint paper by him and his friend Dr Traill appeared in *The Philosophical Transactions of Edinburgh*, vol. ix.

In 1839 he was appointed to the vicarage of the vast parish of Bradford, in his native county, where he sedulously endeavoured to promote the religious and temporal interests of his parishioners. He was especially sedulous to secure the education of the young, while attending to the improvement of their elders. His conscientious discharge of these duties became too much for his health, and after some time he found it necessary to resign his charge, and to retire to Torquay, in Devonshire, which became his future home. He made a short voyage to North America in 1844.

He lost his second wife in 1847. Soon after this severe blow, his love of science, and the hope of improving navigation by magnetic observations, led him in 1847 to undertake a second voyage to the United States of America,

where he remained till March 1848. He was received with much respect by our Transatlantic brethren, who appreciated his scientific character; and he returned to Europe much pleased with his reception on the other side of the Atlantic.

In 1849, while at Torquay, he met with Miss Georgina Ker, who became his third wife, and added much to his happiness. While residing at Torquay, Scoresby volunteered his gratuitous services as a clergyman to assist the minister of Upton Church, which were thankfully accepted, and much valued by the congregation.

His zeal for the improvement of navigation in iron ships induced him to project a voyage to the southern hemisphere, and his young wife determined to accompany him to Australia. They sailed from Liverpool on 10th February 1853. After remaining in that colony for one month, they returned to Britain on 12th August of that year. During the voyage out and home he made numerous most important observations on the local magnetism of the ship in different positions; and he showed that the best position for the regulating compass was at the main-masthead, as farthest removed from the causes disturbing the magnetic needle; and that by comparing this compass with the usual binnacle compass, the local attraction of the ship could be corrected sufficiently for the purposes of navigation. In the ordinary position of the compass, it is liable to be seriously affected by the local attraction of the ship, in which every upright piece of iron becomes a magnet, with its north pole at its lower end in the northern, and its south pole above in the southern hemisphere.

His papers on magnetism, and the journal of this voyage, were given to General Sabine for publication, who committed the task to Archibald Smith, Esq., who has brought them out under the title of *Journal of a Voyage to Australia, and Round the World, for Magnetical Research*.

For some time after his return, his health appeared unbroken; but his respiration began to be affected rather seriously in the winter of 1856. At that period he went to Edinburgh to deliver some lectures in the Philosophical Institution, on the Polar regions, and was taken seriously ill during one of those lectures. After a partial recovery, he paid a visit to Sir M. Shaw Stewart; but his chest now became seriously affected. He returned home, suffered much from dyspnoea, lingered until the 21st of March 1857, when he expired, after severe suffering, which he bore with Christian fortitude and resignation.

The merits of this remarkable man are well known to the scientific world; and his career as a Christian pastor was marked by an earnestness and energy that demand the warmest approbation. Many of his philosophical observations have been published in different parts of Europe, and obtained for their author the high honour of his enrolment among the corresponding members of the French National Institute. His truly amiable disposition endeared him to numerous friends, who honoured him when living, and regretted the loss that society sustained by his decease.

(T. S. T.)

SCOT, REGINALD, a very judicious writer in the sixteenth century, was the younger son of Sir John Scot of Scotshall, near Smeeth, in Kent. He studied at Hart Hall in the University of Oxford, after which he retired to Smeeth, where he lived a studious life, and died in 1599. He published the *Perfect Platform of a Hop-Garden*; and a book entitled the *Discovery of Witchcraft*, 1584, in which he showed that all the relations concerning magicians and witches are chimerical. This admirable work was not only censured by King James I. in his *Dæmonology*, but by several eminent divines, among whom we may mention Meric Casaubon, and Glanvil, author of the *Scepsis Scientifica*. All the copies of this obnoxious book that could be found were committed to the flames.

HISTORY OF SCOTLAND.

Scotland.

SECT. I.—*Roman Period.*A. D. 85 to
446.

It will not be expected that in such a sketch of the history of Scotland as is alone suited to this work, we should enter into the great controversy concerning the origin of the Scottish people, a subject upon which much needless acrimony, and many unprofitable volumes, have been thrown away.¹ It will be more suitable to mark the progress of the great events in our national history, and to pass over its minor features; to fix the attention upon results rather than to perplex it with details; to establish a series of points by which an intelligent reader may guide his memory and direct his studies; and occasionally to note those authors from whose pages he may fill up the picture.

Julius Cæsar.
Before
Christ, 55.

It is well known, that our first authentic knowledge of Britain comes from Julius Cæsar. Fifty-five years before the Christian era, this extraordinary man invaded the island from Gaul; but his operations were attended with little success, his stay was brief, and it is certain that he knew nothing of Scotland. It was not till nearly a century and a half after Cæsar's descent, and during the reign of the emperor Vespasian, that Julius Agricola, at the head of a Roman army, penetrated into the northern parts of Britain. The details of his various campaigns, the resistance which he encountered, and the vestiges of his progress which yet remain, have furnished matter of laborious investigation to our antiquaries. Among their conflicting accounts, it seems certain that he first pushed his conquests as far as the Friths of Forth and Clyde; that in succeeding campaigns he penetrated northwards; and that in his last great expedition, during which his army was accompanied by a numerous fleet, which sailed along the coast, he was opposed by a barbarian chief named Galgacus. A sanguinary battle was fought between this leader and Agricola, the exact site of which has been keenly disputed. There seems to be little doubt, however, that previously to its occurrence the Roman general had passed the Frith of Tay, and that although victorious over the fierce and undisciplined multitudes which opposed him, he experienced a check which compelled him to desist from any further aggression. Two great events marked the last years of the government of Agricola. He explored the northern coasts of Scotland by his fleet; and to him the Roman world, in all probability, owed its first certain knowledge that Britain was an island. He endeavoured, in the second place, to secure his conquests from future attack by a chain of forts connecting the Friths of Forth and Clyde. Having completed these defences, he was recalled by the jealousy of Domitian, and left Britain in the year 85.

Hadrian.

From this time till the reign of Hadrian, a period of thirty-six years, we hear little of the Romans, either in southern or northern Britain. Early in the second century, (A. D. 121), this emperor in person made an expedition into Scotland;

and about twenty years later, Lollius Urbicus, the Roman Scotland governor under the emperor Antoninus, distinguished himself by the courage and ability which he displayed against the turbulent and warlike tribes which inhabited the northern parts of the island. Two facts, however, are admitted by the Roman writers, which demonstrate how uncertain was the tenure by which these masters of the world held their northern possessions in Britain. The emperor Hadrian, apparently distrusting the sufficiency of the line of forts already formed by Agricola, constructed a wall or fortified rampart from the Tyne to the Solway. It has been supposed by some antiquaries, that the emperor entirely abandoned to the barbarians the wide country between this new defence and the more ancient *Vallum* which united the Friths of Forth and Clyde; but the discovery of a succession of coins along the line of this last rampart, belonging to the intermediate emperors, appears to indicate the contrary.² From the adoption of this measure it is however evident, that the courage and successes of the barbarians had given much annoyance to the Romans; and this is corroborated by the second fact to which we allude, namely, that between the period of Hadrian's death and the succession of Antoninus Pius, (A. D. 138), the wall between the Forth and Clyde had been so completely destroyed, that Lollius Urbicus entirely reconstructed it. This fact is proved by inscriptions, which the reader may consult in Horsley's *Britannia Romana*.³ During the remaining years of his government, this able officer devoted himself to opening up the country by roads; to the construction of various camps and fortalices, of which the site has been traced with much industry and success by the latest writer on the subject; and to the introduction of those useful arts which were best calculated to raise and humanize the character of the northern barbarians. His administration in Britain appears to have terminated with the death of his master, Antoninus Pius, A. D. 161.

From this period till the beginning of the third century, all is dark in Britain. But in the year 207, the emperor Severus received intelligence that the Caledonians had invaded the Roman provinces; and with a vigour and alacrity which, considering the distance of the seat of war, and the barren prize to be contested, is not easily explained, he hastened in person to reduce the insurgent Caledonians. This expedition, making every allowance for the exaggeration with which the exploits of an emperor were usually recorded, must have been an extraordinary one. In the comparatively civilized country which extended between the walls of Hadrian and Antoninus, he could meet with little opposition; but when he left this last line of defence, and conducted his army into the wild regions beyond the Frith of Forth, ultimately penetrating into Moray, we must suppose him to have encountered very formidable obstacles. The savage and uncultured state of the country, the extent of the forests, the unhealthy and

Severus.
A. D. 207.

¹ The reader is referred to Innes's Critical Essay on the ancient Inhabitants of Scotland, as the best work yet written on this subject. Its arrangement is defective; but its good sense, and the authenticity of the documents upon which its deductions are founded, are highly praiseworthy. Pinkerton's Dissertation on the Scythians or Goths, Dr. Jamieson's Dissertation on the Origin of the Scottish Language, and the first volume of the laborious work of Chalmers, entitled Caledonia, may be consulted with the greatest advantage. In their pages, the critical student who may desire to pursue the subject, will find ample references to all the noted works upon this question.

² Chalmers's Caledonia, p. 116.

³ Horsley's Britannia, Rom. l. i. c. 10; Innes's Critical Essay, vol. i. p. 12. The remains of the wall are popularly called Grim's Dyke. Grym in Welsh and Cornish, signifies strong, and is used perhaps metaphorically, as Chalmers conjectures, for a "strength or a rampart." Caledonia, vol. i. p. 129.

⁴ We may here refer the critical reader to Chalmers's dissertation on the actions of Lollius Urbicus, contained in the first volume of his Caledonia.

Scotland. interminable marshes, the mountainous ranges which presented such formidable obstacles to the march of a regular army, the rivers, of which the fords were unknown, and the want of subsistence for his troops, except what he carried along with him, must have combined to throw infinite difficulties in his way. The classical writers who have described his campaign inform us, in general terms, that he was obliged to fell the forests, to drain the marshes, to open up the country by roads, and to construct bridges; and they affirm that the Roman emperor did not retrace his steps till he had proceeded so far north, that the soldiers remarked the extraordinary length of the days and shortness of the nights, in comparison with those of Italy.¹ There seems good reason to believe that the spot where the Roman eagles terminated their flight in this memorable expedition, was the promontory separating the Cromarty and the Moray Friths. Here, according to Chalmers, the Caledonians sought for peace, surrendered their arms, and relinquished a portion of their country.² The critical student must pardon the vagueness of these expressions, as the historians of the time do not enable us to be more definite.

Severus retired to York in a feeble state of health; but it was not to repose upon his laurels, for scarcely had he reached that station when news arrived that the Caledonians were again in arms. Irritated by disappointment and disease, he determined instantly to renew the war; intrusted the leading of the army to his son Caracalla; and issued orders to spare neither age nor sex. But death happily arrested these inhuman projects. The emperor expired at York, and the son does not appear, on any good evidence, to have executed the orders of the father.

Previously to his celebrated northern campaign, Severus is said to have reconstructed the rampart originally built by Hadrian between the Tyne and the Solway; a circumstance from which there arises a strong presumption that the Caledonians had encroached upon the Roman provinces, and regained much of the intermediate country between the walls of Hadrian and Antoninus.

From this period, (A.D. 211), which marks the commencement of the third, to nearly the middle of the fifth century, (446), the Romans appear to have abandoned all thoughts of extending their conquests. The vast fabric of their empire was now, as is well known, in a state of melancholy feebleness and decay; attacked on every side by those fierce tribes who were destined to destroy it; and unable to retain provinces far nearer and more important than those in Britain. For some time, however, an effort was made to defend the northern Romanized Britons from the repeated incursions of the Caledonians. In the commencement of the fourth century, (A.D. 306), Constans revisited Britain for this purpose; in the year 368, after a sanguinary and destructive invasion of the barbarians, a temporary tranquillity was restored by the arms of Theodosius; in 398, Stilicho, alarmed by new excesses and increasing weakness in the northern provinces, sent such effectual aid as enabled the Roman governors once more to repel the enemy; and, lastly, in the year 422, the emperor Honorius, having in vain endeavoured to rouse the provincial inhabitants to a vigorous effort in

their own defence, sent a legion to their assistance, by whose efforts the fortifications of the two walls were repaired, and the barbarians once more driven back into their more northern seats. But this was the last relief which could be wrung by her miserable children from a parent who was herself expiring; and it secured for them but a brief period of tranquillity. Imperial Rome, with a tardy and ostentatious justice, conferred freedom on the southern Britons; and restoring a country which she was no longer able to hold, informed them that henceforth they must trust to their own efforts for the defence of their independence. Having given this parting advice to men who appear to have been little able to follow it, the Romans abandoned Britain for ever.

SECT. II.—The Pictish Period.

In the brief sketch which has been given of the Roman A.D. 446 dominion in north Britain, which extended from the year to 843. 85 to 446, a period of little more than three centuries and a half, we have seen that the Romanized Britons were constantly exposed to the invasions of their more northern neighbours, who threatened at last to wrest from them the whole of the country, which had been fortified by Roman skill and mainly defended by Roman soldiers. The question now arises, who were these fierce and indomitable tribes? And to this inquiry, in which antiquaries have spilt almost as much ink as the Romans did blood, the research of a laborious writer enables us to give a satisfactory answer. It appears from the investigation of Chalmers that "at the epoch of Agricola's invasion, the ample extent of north Britain was inhabited by one-and-twenty tribes, who were connected by such slight ties as scarcely to enjoy a social state. These were the *Ottadini*, who appear to have occupied the whole extent of coast from the southern Tyne to the Frith of Forth;³ the *Gadeni*, whose seats lay in the interior country, from the Tyne on the south to the Frith on the north; the *Selgovæ*, whose western boundary was the Dee, and their southern limit the Solway Frith; the *Novantes*, who inhabited the midland and western parts of Galloway; and the *Damnii*, who possessed the shires of Ayr, Renfrew, and Stirling, with a portion of Dunbarton and Perth. Such were the five tribes," says this author, "which occupied, during the first century, that ample region extending from the Tyne and the Solway on the south, to the Forth and the Clyde on the north, varying their limits with the fluctuations of war, conquest, or internal dissensions, during the succession of many ages."⁴ Beyond the Forth we find the *Horestii*, the *Venricones*, the *Taixali*, the *Vacomagi*, the *Albani*, the *Attacotti*, the *Caledonii*, the *Cantæ*, the *Logi*, the *Carnabii*, the *Catini*, the *Mertæ*, the *Carnonacæ*, the *Creones*, and the *Epidii*. The names of these twenty-one original tribes, which are taken from Chalmers, are by him transcribed from the account of Ptolemy, checked by the ancient treatise and map of Richard of Cirencester.⁵ Of the manners of this ancient people, it is impossible, in the absence of all authentic documents, to speak with certainty. From the general account given by Cæsar, they were little removed in the scale of social life or of civil government

¹ Caledonia, vol. i. p. 186, 187.

² The son of Severus is indeed affirmed to have fought on the banks of the Carron with the heroes of Ossian; but much has yet to be proved before we venture to transplant these shadowy contests into the field of history.

³ Including the half of Northumberland, the eastern portion of Roxburghshire, all Berwickshire, and East Lothian.

⁴ Caledonia, vol. i. p. 62.

⁵ It ought however to be stated, that some grave doubts hang over the genuineness of this early writer. Dr. Stukeley's account of him is vague, and the story told by Professor Bertram regarding his discovery of the manuscript and the map is still more suspicious. I have abstained from giving from Chalmers the exact limits of the possessions held by the last sixteen tribes, who inhabited the whole extent of country beyond the Forth to the extremity of Caithness. The research and erudition which he has displayed is entitled to all praise; but it is difficult to believe that the boundaries of these remote, fierce, and wandering aborigines should be ascertainable with as much precision after the lapse of eighteen centuries as the *marches* of Middlesex or Yorkshire. Two points, however, and these of leading importance, Chalmers conceives that he has established: the first, that Britain, from its extreme southern to its most remote northern point, was peopled from Gaul; and the second, that the aborigines over the whole island were a Celtic race.

Scotland. from the rudest savages. They led a pastoral life, living on the milk of their flocks, or the produce of the chase; they were polygamous and idolatrous; their religion, which was Druidical, was stained with human sacrifices; and their rude form of civil government was intimately connected with their religion. They were armed with slight shields, short spears, and daggers; and sometimes fought in small cars, which were drawn by little spirited horses. They rather burrowed in huts than lived in houses, went naked from choice, were brave to excess, capable of enduring all sorts of privation and fatigue, and had such loose ideas of property, that Dio does not hesitate to call them robbers. This character, with the exception of their Druidical form of worship, exhibits little more than the general features of every savage people; and there seems no reason to believe that the lapse of three centuries created any great change in those fierce and indomitable tribes which, inhabiting the more northern parts of the island from the Forth to Caithness, and latterly wresting from the Romans the provinces which they had subdued, were never brought under the yoke, or humanized by the arts of that great people.

A.D. 446. At the period of the Roman abdication, we find that
The Picts. north Britain was inhabited by the descendants of the Caledonian clans which we have enumerated, who, under the name of Picts or Picti, became for four centuries the predominating nation in Scotland. Among these we must be careful to distinguish the five Romanized tribes who possessed Valentia, or the country between the walls of Agricola and Antoninus, not as a race of different descent, but of improved civilization, while their fiercer brethren beyond the Forth bore fresh upon them all the stamp of barbarian life. The name of Picti is conjectured to be derived from Peithi, a British word which characterises *those that are without*, or the people of the open country.¹

Thirty-eight Pictish kings. It would be a vain, and in a sketch of this nature, an idle labour, to enter upon the obscure and sanguinary annals of the Pictish period; an era upon which, to use a quaint expression of Chalmers, archæology is loquacious, and history silent. From an ancient manuscript, first printed by Innes,² and which had belonged to Lord Burleigh, this author has given us a list of their kings, from Drest, who succeeded in the middle of the fifth century, (A.D. 451), to a prince named Bred, who died about the middle of the ninth century, (A.D. 843). During the four centuries which elapsed between the accession of the first and the last of these monarchs, thirty-eight Pictish kings are enumerated. Of their authentic history there is scarcely a vestige; but the blank has been filled up by the fables of Boyce, which unhappily were afterwards embalmed in the elegant Latinity of Buchanan.

Rise of the kingdom of Strathclyd. Some points in this period, however, have been ascertained, and they are well worthy of notice. We have already seen, that on the entire abdication of Britain by the Romans, the five tribes which inhabited Valentia were declared independent. They were no longer provincial subjects of Rome, but a free, though an effeminate people. The constant attacks of the Picts rendered it necessary for them to unite in their own defence; and from this union arose a new kingdom, denominated by ancient authors sometimes the *Regnum Cumbrense*, or more frequently the kingdom of Strathclyd. It appears to have included the present Liddesdale, Teviotdale, Dumfries-shire, Galloway, Ayrshire, Renfrew, Strathclyde, the midland and western parts of Stirlingshire, with the largest portion of Dunbartonshire.³ "The metropolis of this kingdom," says Chalmers, "was Alclyd, a city which they still retained when the pen dropt from the hand of the venerable Bede, in 734, and which is situated on the north bank of the Clyde, at the influx of the Leven. The

descriptive name of Alclyd, which signifies the rocky height on the Clyde, was applied to the bifurcated rock, on the summit of which these associated Britons had a strong hill fort, which formed a secure residence for their reguli or kings. To this fortress the Scoto-Irish subsequently applied the name of *Dun-Briton*, signifying the fortress of the Britons, an appellation which, by an easy transition, has in modern times been converted into Dunbarton.⁴ Among the little kings who reigned over Strathclyd, there are none whose names or exploits are worthy of preservation, with the single exception of the semi-poetic Arthur. It is sad King that the severer hand of history should strip this glorious Arthur. "Childe" of his many-coloured robes, and reduce him to the cold reality of a Cumbrian Pendragon. At the commencement of the sixth century, Arthur, the chief military leader or Pendragon of the Cumbrian Britons, expelled his sovereign, Hual or Hoel, from Strathclyde, and commenced a reign of which it is impossible to separate the facts from the fictions with which they have become incorporated.

But the Pictish period is not only distinguished by the rise of a new kingdom, it is marked by the arrival in Scotland of a new people, the Saxons, a race of Gothic origin, who invaded and finally effected a settlement in Lothian. This remarkable event, so important in its remote consequences upon our national history, took place in the middle of the fifth century (A.D. 449). It was not difficult for the Saxons, a people who certainly were far their superiors in courage and in arms, to subdue the feeble race of the Otadani. They do not at first appear to have attempted to push their conquests to the northward of the Forth, but contented themselves with the occupation of a portion of the province of Valentia. After the lapse of a century, however, Ida, one of the boldest and most adventurous of the sons of Woden, landed at Flamborough, and brought an important accession to the strength and numbers of his countrymen. It was by this great chief that the Saxon kingdom of Northumbria was founded; nor was he arrested in his victorious career, till he had extended his dominions from the Humber to the Forth. Ida was succeeded in the Northumbrian kingdom by Aella, and Aella by Ethelred, under whose reigns occurred no event of importance; but Edwin his successor, who came to the throne in the beginning of the seventh century, appears to have added essentially to the extent of the Saxon conquests, and to have impressed not only the southern Britons, but his fiercer and more northern neighbours the Picts, with the terror of his arms. There appears little doubt that Edinburgh or Ed-burgh or winsburgh, the present capital of Scotland, owes its foundation to this energetic Saxon chief.⁵

Hitherto, in speaking of the northern inhabitants beyond the Forth, we have designated them by the single appellation of the Picts. We must now mark the arrival of a different people, although probably sprung from the same ancient stock.

At the commencement of the fourth century, we find that the ruling or dominant people in Ireland were the Scots, a Celtic race; and although there is no sufficient evidence that they had formed any permanent settlement in Britain previously to the abdication of the island by the Romans, it is certain that in the year 360 they invaded the Roman provinces in that kingdom, and were repelled by Theodosius. In the beginning of the sixth century, three Irish chiefs, Loarn, Fergus, and Angus, sons of Erc, king of Dalriada, by which we are to understand the province of Ulster, led a colony into the ancient province of the British Epidii, and effected a settlement upon the promontory of Kentire.⁶ As far as any light is afforded by the Irish annals, in this occupation of Kentire the Scoto-Irish met with but feeble opposi-

Scotland. tion; and a long period of obscurity succeeds, in which little more is distinguishable, except the fact that a series of Scoto-Irish kings, or reguli, are found in Scotland, from the commencement of the fifth century, (503), when Fergus held the throne, till the accession of Kenneth, the son of Alpin, who reigned from the year 836 to 843, under whom the ascendancy of the Scoto-Irish or Scotch, appears to have been established. Upon this portion of our history we are tempted to transcribe the following observations of Chalmers.

A.D.
503-843.

"In the records of time, there scarcely occurs a period of history so perplexed and obscure, as the annals of the Scoto-Irish kings and their tribes. The original cause of this obscurity is the want of contemporaneous writing. An ample field was thus left open for the contests of national emulation. Ignorance and ingenuity, sophistry and system, have all contributed to make what was dark still more obscure. The series and genealogy of the kings have been involved in peculiar perplexity by the contests of the Irish and Scottish antiquaries, for pre-eminence in antiquity, as well as in fame. And Cimmerian darkness has overspread the annals of a people too restless for the repose of study; too rude for the elaboration of writing."¹ After such an acknowledgment, it would be idle labour to follow this indefatigable inquirer into the twilight-history of these times; but this period is distinguished by one great event which shines brightly amidst the surrounding gloom, namely, the conversion of northern Britain to Christianity.

Conversion
to Christi-
anity.

Already the Romanized Britons of the South had received the true faith, and the Scoto-Irish appear to have been converted to Christianity by St. Patrick, previously to their establishment in Kentire. St. Ninian, himself a Briton, though educated as a monk at Rome, had, in the commencement of the fourth century, founded a monastery in Galloway; and in the sixth century, St. Kentigern signified himself by his pious labours among the Britons of Strathclyde; but the conversion of the northern Picts was reserved for St. Columba.

Columba.
A.D. 521.

This great and good man was born in Ireland, in the year 521. His descent was royal, and his education was at first carefully conducted under the best masters which his native island, long before this converted to Christianity, could supply. Of these the most noted was St. Ciaran, the apostle of the Scoto-Irish of Kentire; and from him, in all probability, Columba imbibed his first desire to introduce the gospel into the desolate and barbarous dominions of the northern Picts.

A.D. 568.

It was in the year 568, that embarking with twelve of his friends, in a boat of wicker work which was covered with hides, he set out upon his benevolent mission, and landed in the Island of Hy, or Iona, which was situated near the confines of the Scottish and Pictish territories. The difficulties which he had to encounter on his first arrival, were of the most formidable kind. He found a people so barbarous that his life was attempted; the king, when the holy man first approached his residence, ordered its gates to be shut against him; the priests, who were druids, and possessed much influence, employed all their eloquence to counteract his efforts; and the nature of the country, woody, mountainous, and infested with wild beasts, rendered travelling most dangerous and painful.² It is also said that at first the saint required an interpreter to make himself intelligible, although after a short residence he appears to have found little difficulty in conversing with the barbarians. But none of these obstacles was sufficient to baffle the zeal and courage of Columba; and so blest were his labours, so rapid the effects produced by the example of his virtues, that in a few years the greater portion of the Pictish dominions was converted to the Christian faith; churches were erected, monasteries established, in various places, and Columba,

Scotland. as primate, became an object of the utmost love and veneration among the barbarous tribes, and fierce and warlike princes whom he had called from darkness into light. At that time his monastery was perhaps the chief seminary of learning in Europe. It was from this nursery, that not only all the monasteries, and above three hundred churches which he himself had established, were supplied with learned pastors, but which also gave divines to many of the religious establishments among the neighbouring nations.³ Columba died in the year 597, in the seventy-seventh year of his age; a man not less distinguished by his zeal and labour in the dissemination of the gospel, than by the simplicity of his manners, the sweetness of his temper, and the holiness of his life.

A.D. 567.
Death of
Columba.

We have already observed, that it would be foreign to the object of this historical sketch, to involve our readers in the dark and wholly uninteresting annals of the Pictish kings. But one remarkable event must not escape our notice, we mean the disappearance of the Pictish people after the middle of the ninth century. There seems every reason to believe, that the story of the total extermination of the Picts by the sword of the victorious Kenneth Macalpin, is a fable invented at a later period, and certainly supported by nothing approaching to contemporary evidence. A more rational and intelligible account ascribes this event, not to the destruction, but to what may more correctly be denominated the absorption of the Picts by the predominating nation of the Scots. Both were probably a people of the same race, speaking a similar language, and little different in their manners and civil government. Both were animated by the emulation of outstripping each other in power and extent of territory; and this led to protracted struggles, in which the Picts maintained their independence with difficulty, and the Scots, gradually enlarging their dominions, acquired a predominating influence. Such being the relative condition of the two nations, an event took place which united in one person the claim to the Pictish and the Scottish throne.⁴

Achais or Eocha, king of the Scots, who died in the year 826, had married Urgusia, a Pictish princess, the sister of Constantine and Ungus, successively kings of the Picts. His grandson was Kenneth Macalpin, a prince of great hardihood and ambition, who succeeded to his paternal throne in 836. On the death of Uven, the Pictish monarch, in 839, Kenneth asserted his claim to the Pictish throne, in right of his grandmother, Urgusia. The feeble state of the nation, and the incapacity of the true heir, combined to favour his ambitious designs; and after a struggle of three years, he succeeded in uniting the two crowns in his own person.⁵ The observations of Chalmers upon this event, and the important consequences which it drew after it, are well worthy of notice. "During such confusions," says this author, "amidst a rude people, whose forms of government were little fixed, and whose laws were less regarded, the loss of a battle, or the death of a king, was an adequate cause of an important revolution. Of all these events, Kenneth dexterously took advantage; and finding a feeble competitor, he easily stepped into the vacant throne. In his person a new dynasty began. The king was changed, but the government remained the same. The Picts and Scots, who were a congenial people, from a common origin, and spoke cognate tongues, the British and Gaelic, readily coalesced; yet has it been asserted by ignorance, and believed by credulity, that Kenneth made so bad a use of the power which he had adroitly acquired, as to destroy the whole Pictish people in the wantonness of his cruelty. To enforce the belief in an action which is in itself unknown, and so inconsistent with the interest of a provident sovereign, requires

Scotland. stronger proofs than the assertions of uninformed history, or the report of vulgar tradition. The Picts continued throughout the succeeding period (from 843 to 1097) to be mentioned by contemporary authors, though they were governed by a new race, and were united with a predominant people.¹

SECT. III.—*The Scottish Period.*

A.D. 843–1097. The union of the two nations of the Picts and the Scots, under one powerful prince, forms the commencement of the third great division of Scottish history, which extends from the middle of the ninth century (843) to the expiration of the eleventh (1097), a period of two centuries and a half.

Extent of the Pictish and Scottish kingdoms. For ages before the time of this union, the Pictish dominions were confined by the Forth on the south, Drumalban on the west, and the German Ocean on the east and north; while at the period of its occurrence the Scots possessed the whole western coast, from the Clyde to Loch Torridon, with the extensive kingdom of Argyle, which stretched its arms from the Clyde on the south to Loch Eir and Loch Maree on the north, and reached from the sea on the west to Drumalban² on the east. These extensive dominions were now united; the name of Scotia, as marking the whole kingdom, gained ground over that of Pictavia; and from the tenth century (934), when the Saxon Chronicle first mentions *Scotland* as invaded by Athelstan, this distinctive appellation for the kingdom of North Britain gradually gained ground till it excluded every other.

It has been observed by Sir Walter Scott, "that the descendants of Kenneth Macalpine pass us in gloomy and obscure pageantry, like those of Banquo in the theatre;" and it might have been added, that the impression left upon the mind by the perusal of their various reigns is as shadowy and unsubstantial. To fatigue and perplex the reader, by a detail of historical passages, which led to no great results, is not the purpose of this sketch, but to mark the features which prominently distinguish the period. Nor were these either few or unimportant.

Invasions by the Danes. 1. The first event which demands our notice, is the commencement of those invasions by the Danes, which for several centuries continued to be the greatest scourge of Scotland. It was under the reign of Constantine, the second monarch in succession from Kenneth, that these fierce pirate leaders, known under the name of *Vikinghr*, or sea-kings, first made their appearance in North Britain. Having established a settlement in Ireland, they soon became acquainted with the commodious havens of the Scottish coasts; and after a partial visit in 866, a more formidable armament sailed from Dublin, under Anlaf and Ivar, in 870. During this invasion, they took Alcluyd, or Dunbarton, ravaged the whole extent of North Britain, and returned glutted with slaughter and booty to Ireland. These sea-wolves having once tasted blood, were not slow to return. Thrice under the same reign were their vessels seen on the coasts of the devoted country, in 871, 875, and 876; and at last, in 881, the Scottish monarch met his death on the banks of the Forth, in an ineffectual attempt to defend his people, and repel their ravages. Reappearing under the reign of Donald, who succeeded to the throne in 893, they were defeated on the banks of the Tay, in the vicinity of Scone, and again, in 904, repulsed by the same prince, who lost his life, after he had slain their leader. This, however, did not prevent their return in 907, and afterwards, in 918, under the reign of Constantine the Third, who, with the assistance of the northern Saxons, encoun-

tered and repulsed them at Tinnmore; a check which appears Scotland for a considerable period to have given repose to the kingdom.

In 961, under the reign of Indalf, who had succeeded to The Danes the throne in 953, the Vikinghr made a descent in the bay repeatedly defeated them in a desperate action, in which he lost his Scotland. life. In 970, Kenneth the Third, who is represented as a.A.D. 970 monarch of extraordinary vigour and ambition, succeeded to the throne, and under his reign the Danes reappeared with a numerous fleet in the Tay; but after a sanguinary struggle, in which they at first succeeded, were ultimately defeated by the bravery of the Scots, commanded by Kenneth the Third in person. This contest, which appears to have been attended with an enormous loss on both sides, took place at Luncarty, where many tumuli still remain, to mark the field of battle.³

After this the country enjoyed a quiet of nine years; but Danes de- in 1003, the Norsemen, who had now for some time perma- feated at nently settled themselves in Orkney, again made their Mortlach appearance in great strength upon the coast of Moray. They by Malcolm seized and fortified the promontory known by the name of the Second. A.D. 1010. the Burgh-head of Moray, where they found a commodious harbour, and from which, in 1010, they led an army to plunder that fertile region. But they were met and defeated with great slaughter by Malcolm the Second, in the battle of Mortlach, where the king, in gratitude for his victory, endowed a religious house, which became the seat of the earliest Scottish bishopric.

These repeated repulses checked and disheartened the Treaty be- pirate kings; but they disdained to relinquish the contest. tween Mal- Their last efforts appear to have been made on the coast of colm and Angus and Buchan, where they were repulsed in succes- Sweno, sive conflicts, fought at Aberlemno, Panbride, and Slaines A.D. 1014. Castle. At length a convention, or pacific treaty, was en- Final de- tered into between Malcolm, and Sweno, king of Denmark, the Danes. in the year 1014, which was followed by the evacuation of the Burgh-head of Moray, and the final departure of the Danes. Thus, after a severe struggle, which at various intervals, and with various success, appears to have continued for nearly a century and a half, (866 to 1014), the energy of the Scots ultimately triumphed over the efforts of the Norsemen; and while the Danish rovers established themselves in some of the finest countries in Europe, and in England alternately fixed themselves as permanent settlers, or extorted an odious tribute as the price of their absence, Sweno, though one of their most powerful princes, found himself at last compelled to desist from the contest.

2. The second event of importance which marked this pe- Acquisition riod, was the enlargement of the Scottish provinces of Mal- tion of colm the First, by the pacific acquisition of Cumberland and by Cumberland from Edmund the Saxon king of England. Against this land by young prince, the Danes, who had established themselves the First. in the northern part of his dominions, declared war, and calling the Norwegians to their assistance, threatened to subdue the whole country. Edmund opposed them with great courage and success, reduced Northumberland, then a Danish province, and next turned his arms against Cumbria, or Cumberland. After wasting this little country, then inhabited by the Britons, under their king or chief leader, Dunmail, the English prince, aware perhaps of the difficulty of retaining his new acquisition, delivered it up to Malcolm the First, under the condition that he would become his associate (*medwoertha*) in war, or, as the terms are explained by Matthew of Westminster, "that he would de-

Scotland. fend the northern parts of England from the invasions of his enemies, whether they came by sea or by land.¹ It is to be remembered, that this transaction was entered into between two independent princes, the one of Saxon, the other of Celtic race, more than a century before the feudal usages or tenures were introduced into England by the Normans; an observation which might have been deemed unnecessary, had not some ingenious writers affected to detect in the stipulations of Malcolm the acknowledgment of feudal dependence. In this manner did Cumbria, in the middle of the tenth century, become a portion of the Scottish dominions.²

Kenneth
III.

Conquest
of Strath-
clyd.

3. This treaty was followed by the reigns of Indulf, Duf, and Culen, a dark and sanguinary period, occupied by domestic war and civil commotion; but under Kenneth the Third, who came to the throne in 970, occurred another event of no little moment in the history of the country. This was the conquest of the ancient British kingdom of Strathclyd by the arms of that monarch. We have seen this independent state arise, in the middle of the fifth century, from a union of the Romanized British tribes, who, on the desertion of the island by the Romans, were drawn together by the ties of common danger and mutual defence. From this time, (446), they had, under various reverses and multiplied attacks, enjoyed a precarious independence for upwards of five centuries; nor did they permit themselves to be incorporated in the Scottish monarchy without a determined struggle. The arms and the energy of Kenneth, however, were successful; and one of those gleams of romantic light, which sometimes soften the gloomy annals of these ages, fell on the ruins of Strathclyd. Dunwallon, the last of its kings, after exhibiting the utmost courage and resolution in defence of his people, assumed the religious habit, travelled to Rome, and died a monk.³

Acquisi-
tion of Lo-
thian by
Malcolm
II.

The last prominent feature which marks this period, was the further enlargement of the Scottish dominions, by the acquisition of Lothian, hitherto a part of England. It took place in 1016, under the reign of Malcolm the Second, the son of Kenneth the Third, to whose conquest of Strathclyd we have just alluded. It was this same Malcolm whose courage we have seen victorious over the Danes at Mortlach, and to whose convention with Sweno Scotland owed its freedom from the ravages of the pirate kings. In the beginning of the eleventh century, (1018), this warlike prince engaged in hostilities with Ughtred, earl of Northumberland. Their forces met at Carham, near Werk, on the southern bank of the Tweed, and a sanguinary battle was fought, which effectually checked the Scottish prince. Ughtred, however, having been assassinated, was succeeded by his brother Eadulph, a feebler ruler, who, from a dread of a second invasion, was induced to purchase the friendship of Malcolm, by the cession of the whole of Lothian.⁴

A.D. 1018.

Such are the great features which distinguish the early history of Scotland, from the middle of the ninth to the commencement of the eleventh century, (843 to 1018), and upon which it is both wiser and easier to fix the mind than to crowd and burden it with lists of barbarous and forgotten kings. We see a people, still rude, ignorant, and, except for the sweetening influences of Christianity, little removed from savage life; but we find them able not only to vindicate their freedom against those incessant and cruel invasions, which broke, and for a time subdued the neighbouring country of England, but animated by an ambition which, under successive princes, largely extended their dominions, by the successive acquisitions of Cumberland, Strathclyd, and Lothian. Nor is the remaining portion of

the Scottish period, from 1018 to 1097, unmarked by some great events. In 1031, under the reign of Malcolm the Second, Canute, the Danish king of England, invaded Scotland. This prince, the most powerful monarch of his time, as he possessed not only England, but Denmark and Norway, led an army against Malcolm. The cause of the war is involved in much obscurity. It was however connected with some claim or dispute regarding Cumberland, and it terminated in Malcolm retaining the possession of that province, and performing the conditions upon which it had been transferred to him.⁵

Scotland.
A.D. 1031.

In the historical romance of Boyce, and the classical pages of Buchanan, Malcolm the Second figures as the first and one of the greatest of Scottish legislators. It was referred for the learning and acuteness of Lord Hailes to detect his apocryphal laws as the forgery of a much later age.

Malcolm the Second, whose severe and vigorous reign had been marked by many sanguinary domestic feuds, not necessary to be detailed, was succeeded in 1033 by his grandson Duncan, the "gracious Duncan" of Shakspeare, whose imperishable drama is founded upon a fictitious narrative, which Holinshed copied from Boyce. Let us for a moment, in a spirit rather of homage than of criticism, disentangle the dross of fact from the ore of fiction. Lady Macbeth was the Lady Gruoch, and had regal blood in her veins. She was the grand-daughter of Kenneth the Fourth. Her husband, Macbeth, was the son of Finlegh Maormor, or the supreme ruler of Ross. The real wrongs of the Lady Gruoch, the root of her implacable revenge, were even more deep than those of her mighty counterpart. She had seen her grandfather Kenneth dethroned by Malcolm, her brother assassinated, and her husband burned, griefs amply sufficient to turn her milk to gall. Macbeth, on the other hand, had wept a father slain also by Malcolm; and thus revenge and ambition were equally roused in both their bosoms. The purpose which had been arrested by the superior vigour and courage of Malcolm, was executed on his more feeble grandson. Duncan, in 1039, was assassinated at Bothgowanan, near Elgin;⁶ and Macbeth seized the sanguinary sceptre, which he held with a vigorous grasp for fifteen years, until he was defeated and slain by Macduff, in 1054.

On his death, a contest for the throne arose between Lulach, the son of the Lady Gruoch, and great-grandson of Kenneth the Fourth, and Malcolm Ceanmore, great-grandson of Malcolm the Second; and this struggle terminated in 1057, by the defeat of Lulach, and the accession of his rival, Malcolm, who was contemporary with Edward the Confessor.

The accession of Malcolm Ceanmore to the Scottish throne was soon afterwards followed by an event, which, although taking place in the sister country, produced the most important effects upon the history of Scotland. This was the invasion and conquest of England by the Normans, and the establishment of an entirely new dynasty in that country. The first consequence of this change was favourable to Malcolm, as it led to his marriage with a Saxon princess, whose character had a marked and favourable influence upon the rudeness of her husband and his people. This lady was Margaret, who was the sister of Edgar Ætheling. It is important to trace her lineage. Canute, the Danish king of England, had banished Edwin and Edward, the children of Edmund Ironside, the last of the pure Saxon dynasty, for Edward the Confessor was half a Norman. They found a retreat in Hungary, where Edwin died; but from this country Edward, in 1057, was recalled by Edward the Confes-

sister of
Edgar
Ætheling.

Simeon of Durham, apud Twysden, vol. i. p. 81.

Scotland. sor. This prince had three children, a son, Edgar, commonly called Edgar Ætheling, the heir of the Saxon line, and two daughters, Margaret and Christian. On the conquest of England, the nobles of Northumberland, who were principally of Danish origin, led by two chiefs, named Maerleswegen and Gospatric, becoming disgusted at the Norman tyranny, fled to the court of Malcolm, taking with them Edgar and his two sisters. Edgar was weak, almost to imbecility; and in the event of his dying, or being found incapable of filling the throne, his claims as heir of the Saxon line descended to his sister. She was beautiful, accomplished, and pious; and a union which perhaps, at a distance, had been suggested to Malcolm by ambition, on a nearer view was perfected by love.

Invasion of England. The marriage of the Scottish monarch was soon followed by an invasion of England, in which Malcolm mercilessly ravaged the bishopric of Durham. The manner in which this predatory inroad was conducted marks the ferocity of the times. Malcolm and his subjects were Christians; yet even the churches were destroyed and burnt, while the unhappy persons who had fled to them for sanctuary were massacred, or consumed in the flames. During the occurrence of these savage scenes in England, Gospatric, one of the most powerful of the Northumbrian barons, whose assistance William the Conqueror had secured, swept through Malcolm's territory of Cumberland, and laid waste the country in a miserable manner, upon which the Scottish prince returned home, leading captive, says an English historian, such a multitude of young men and maidens, "that for many years they were to be found in every Scottish village, nay, even in every Scottish hovel."¹

There seems to be little doubt that this expedition of Malcolm was intimately connected with the determined stand made against William the Conqueror by the Northumbrian earls who had carried Edgar Ætheling into Scotland. Combining in 1069 with their brethren, the Danes, who brought a powerful fleet to their assistance, they advanced as far as York, where they put the Norman garrison to the sword; and here it is probable they expected to be joined by Malcolm, but being disappointed in their hope, they made peace with William, who had the address to dissolve the confederacy. Malcolm alone continued faithful to the cause of the Saxon prince; and, though deserted by his confederates, yet by invading England fulfilled his agreement.

William the Conqueror retaliates. This inroad led to a dreadful retaliation on the part of William. "To punish the revolt," we use the words of Lord Hailes, "and to oppose a wilderness to the invasions of the Danes, he laid entirely waste the fertile country which lies between the Humber and the Tees." "At this time," says William of Malmesbury, "there were destroyed such splendid towns, such lofty castles, such beautiful pastures, that had a stranger viewed the scene he might have been moved to compassion, and had one inhabitant been left alive, he would not have recollected the country." Of this fine district the inhabitants seem to have been almost wholly exterminated. Many who escaped the sword died of famine, many sold themselves for slaves, while those of higher quality, Norman as well as Saxon, sought an asylum in Scotland, and found at the court of Malcolm a favourable reception.

Invasion of Scotland in 1072. William having secured peace at home, prepared an armament against Scotland, and in 1072 he invaded that country, both by sea and by land. Malcolm wisely met superior power by an offer of submission. He sought and obtained peace, gave hostages, and performed homage. So far all is certain; but a question arises, for what was this homage performed? The answer may be given in the words of one

of the most able inquirers upon the subject: "According to Scotland. the general and most probable opinion, this homage was done by Malcolm for the lands which he held in England."²

We have already met with Gospatric, the powerful Northumbrian earl who fled from the Conqueror to the court of Malcolm, bringing with him the heir of the Saxon line, with his sisters. Proving treacherous to Malcolm, Gospatric obtained from William the government of Northumberland; but on his return from his successful expedition against Malcolm, the Norman conqueror, from jealousy or disgust, degraded his Northumbrian ally, who once more fled to the Scottish king. Malcolm, on his part, not only forgave him, but presented him with the lands and castle of Dunbar, and the castle of Cockburnspath. He who held these estates, lying on the borders between the two countries, might be said to have the keys of Scotland at his girdle; and the circumstance is worthy of remembrance, not only as marking the origin of a potent family, destined to act a leading part in the future history of the country, but as indicating the policy of Malcolm, who, conscious of the inferiority of his own Celtic race, manifested a wise anxiety to prevail on strangers, whether Normans, Danes, or Saxons, to settle in his dominions.

The remaining portion of the reign of this energetic A.D. prince (1079-1093), is chiefly distinguished by a struggle 1079-1093. with William Rufus, who, upon the death of the Conqueror, had succeeded to the English throne. This prince appears to have withheld from Malcolm part of the English possessions to which he claimed a right; and with the view of compelling a surrender of them, the Scottish king invaded England, and penetrated as far as Chester, on the Were. Rufus led against him a superior force; and Malcolm, aware of his approach, prudently declined a contest, and by a timely retreat, secured his plunder and his captives.

This appears to have taken place in May 1091; and in Rufus invades Scotland, A.D. 1091. the autumn of the same year, the Norman prince, having equipped a fleet, and levied a numerous land force, led his army in person against Scotland. He continued his march to the shores of the Forth; but here his progress was stayed, in consequence of his receiving intelligence that his fleet had been destroyed by a tempest. There were no vessels to transport his troops across the Forth. The Scots, with a policy which they early learned, and repeatedly practised, had driven away their cattle, and cleared the country of its provisions; and at this crisis, when his soldiers were perishing from famine, Malcolm led his army against the English, crossed the Forth, and advanced into Lothian; a territory originally, as we have seen, acquired from the Angles, and therefore esteemed a part of England, although now subject to the Scottish king. Here having chosen a strong position, he encamped, and avoiding a battle, harassed the enemy, proposing to cut off his supplies, and expel him by famine. While both parties were thus situated, Edgar Ætheling, now with Rufus, and Robert, the king's brother, exerted themselves to conciliate a peace. The English monarch, notwithstanding his fiery temper, knew how to bend his fury to his interest; and Malcolm, perceiving that he could obtain his purpose by treaty, wisely preferred this to the risk of a battle. It is important to mark the conditions of the agreement. William Rufus, we find, consented to restore to Malcolm twelve manors, which the Scottish prince had held under the Conqueror, and to make an annual payment to him of twelve marks of gold.³ Malcolm, on his part, consented to do homage to William, and to hold his lands under the same tenure of feudal service and obedience to him, as he had formerly paid to his father the Conqueror.

Here pausing for a moment upon a subject which has

Scotland.
Question
of homage.

given rise to some discordant opinions, and which, now that the bitterness of national rivalry is at an end, may, we trust, be calmly considered, we would remark that, taking the testimony of English historians as our guide, all as yet seems clear, as to the much debated subject of homage. Simeon of Durham expressly declares that Malcolm agreed to obey William Rufus on the same conditions as those on which he had obeyed William the Conqueror. Under the Conqueror it is certain that Malcolm held twelve manors in England. These Rufus had seized; but he now restored them, and Malcolm renewed his obligation of homage. On a former occasion when, as we have seen, the Scottish king, in 1072, paid his homage to the Conqueror in person, the ground upon which he paid it is equally clear. Previously to the battle of Hastings, the Scottish monarchs had obtained from the Saxon kings some possessions in England. This was before the introduction of the strict feudal tenures, which came in with the Normans; but there is no doubt that these possessions were held under the condition of aiding the Saxon princes in repelling the incursions of the Danes.¹ When William the Conqueror established himself in England, Malcolm, as we have seen, considered him as a usurper of the rights of his brother-in-law, Edgar Ætheling; and, on this ground, as well as perhaps from an indisposition to embrace a system which must have been new to him, he had at first refused to pay his homage for the lands he held in England. Circumstances, however, made him change this resolution. The prevailing power of William, the acquiescence of the English under his government, and the inactivity and imbecility of Edgar Ætheling, his brother-in-law, induced him to desist from a conflict in which he ceased to have an interest. A more intimate acquaintance with the feudal tenures introduced into England taught him that, in the acknowledgment of superiority for the lands which he held in that country, there was no sacrifice of dignity as an independent monarch, and as all idea of restoring Edgar was abandoned, he paid his homage to the conqueror.²

New disputes
between
Malcolm
and Rufus.
A.D. 1092

The point of homage seemed thus prudently settled; but the proud and fiery temper, which appears to have been an infirmity of both princes, soon led to a new contest between Malcolm and Rufus. A jealousy of the incursions of the Scots had formerly led the Conqueror to build two strong castles, the one at Durham, the other at Newcastle. To these his successor now added a third at Carlisle; a barrier which, however necessary, might possibly be considered as encroaching on the freedom of the lands which Malcolm held in Cumberland. A dispute arose, and a personal interview between the two kings having been considered the best mode of settling their differences, Malcolm repaired to Gloucester, where Rufus met him and proposed that he should do homage in presence of his English barons. This the Scottish monarch refused; although he was ready, he said, to perform his homage on the frontiers of both kingdoms, as had been the ancient usage. The reply was angrily received, and the two kings having parted with expressions of defiance, Malcolm assembled an army, and advancing with a speed whetted by the indignity with which he had been treated, burst into Northumberland, which he wasted with fire and sword. Sweeping onwards to Alnwick, he was about to possess himself of the castle, when the Scottish army was attacked by Robert de Mowbray. In the battle which ensued Malcolm was slain, and Edward, his eldest son, shared the fate of his father.

Death of
Malcolm,
A.D. 1093.

We have already observed that the mild and gentle dispo-

sition of his queen, St. Margaret, had an admirable influence over the fierce and impetuous character of this prince. Of her life we have an interesting account from the pen of Turgot her confessor; and we cannot resist borrowing a few touches from this early specimen of biography. When the king set out on his last expedition against England, Margaret was suffering from a fatal and lingering complaint. She only lived to hear of the death of her husband and her son. Her last moments are thus described by that faithful minister, who related what he saw: "During a short interval of ease, the queen devoutly received the communion. Soon after, her anguish of body returned with redoubled violence; she stretched herself upon her couch and calmly waited for the moment of her dissolution; cold, and in the agonies of death, she ceased not to put up her supplications to heaven. These were some of her words: 'Have mercy upon me, O God; according to the multitude of thy tender mercies blot out mine iniquities; make me to hear joy and gladness, that so the bones which thou hast broken may rejoice.' At that moment," continues Turgot, "her son, Edgar, returning from the army, approached her couch. 'How fares it,' said she, 'with the king and my Edward?' The youth stood silent. 'I know all; I know all. By this holy cross, by your filial affection, I adjure you to tell me the truth.' He answered, 'your husband and your son are both slain.' Lifting up her eyes and her hands to heaven she then said, 'Praise and blessing be to thee, Almighty God, that thou hast been pleased to make me endure so bitter anguish in the hour of my departure, thereby, as I trust, to purify me in some measure, from the corruption of my sins; and thou, Lord Jesus Christ, who, through the will of the Father, hast enlivened the world by thy death, oh deliver me.' While pronouncing the words 'deliver me,' she expired."³

Scotland.
Death of
St. Margaret.

"In reviewing the reign of Malcolm the Third," says Lord Hailes, "we may discern a character of steady persevering courage. From his early youth to his last invasion of England, his conduct was uniform. He maintained his throne with the same spirit by which he won it. Though he was the ruler of a nation uncivilised, and destitute of foreign resources, and had such antagonists as the Conqueror and William Rufus to encounter, yet, for twenty-seven years, he supported this unequal contest, sometimes with success, never without honour. That he should have so well asserted the independency of Scotland is astonishing, when the weakness of his own kingdom, and the strength and abilities of his enemies are fairly estimated."⁴

Malcolm's eldest son had fallen, as we have seen, with his father. His remaining sons, Ethelred, Edmund, Edgar, Alexander, and David, were all under age; and his brother Donald, who, on the usurpation of the throne by Macbeth, had taken refuge in the Hebrides, appears to have remained in that distant retreat during the whole reign of the late king. These islands were then independent of the Scottish crown. They were inhabited by a warlike race, whose chiefs yielded to the Norwegian king a fluctuating subjection; and many of these leaders having joined him, Donald, with a powerful fleet, invaded Scotland and seized the crown; but it was for a very brief season. Duncan, a son of Malcolm, but illegitimate as is generally believed, had, in 1072, been delivered to William Rufus as a hostage for his father's fidelity. He had received his education at the Norman court, and having been knighted by the English monarch, was retained in his service. With permission of William, he now invaded Scotland, and assisted by a hand

² In this account of the expedition of William Rufus into Scotland, and in the remarks on the disputed point of the homage, we have been induced to treat the subject a little more in detail, availing ourselves of some manuscript notes of the late David Macpherson, a writer of great research and judgment. This seemed the more necessary, as the subject of Rufus's invasion of Scotland, and Malcolm's stipulated homage, has been considered by high authority as one involved in extreme obscurity.

³ Hailes's Annals, vol. i. pp. 40, 41, 4to edit. We have availed ourselves of Lord Hailes's translation of the passage from Turgot describing the queen's death.

⁴ Ibid. vol. i. pp. 25, 26, 4to edit.

Scotland. of English and Norman adventurers expelled Donald Bane. He, in his turn, after a reign of little more than a year, was assassinated, and Donald once more ascended the throne, from which, in 1097, he was again expelled by William Rufus, who dispatched Edgar Ætheling with a powerful army into Scotland. By this prince the aged usurper was defeated, and Edgar, the son of Malcolm and Margaret, the nephew of Edgar Ætheling, ascended the throne. This event took place in the close of the eleventh century; and, with the captivity and death of Donald Bane, who is the last of the race of Scoto-Irish kings, the Scottish period expires.

Edgar.
A.D. 1097.

And here, after having passed over a portion of our history which extends from the middle of the ninth to the end of the eleventh century, let us pause to say a few words on the condition of the church, the state of the laws, and the manners of the people. To every critical student of this period one thing appears certain. Throughout its whole extent, we find the predominant people a Celtic race. The laws were Celtic, the government Celtic, the usages and manners Celtic, the church Celtic, the language Celtic. "If," says Chalmers, "Malcolm Canmore, a Celtic prince, who did not arrogate the character of a lawgiver, had been disposed to effect a considerable change in this Celtic system, he would have found his inclination limited by his impotence. The Scottish kings, during those times, seem not to have possessed legislative power. Whenever they acted as legislators, they appear to have had some coadjutors; either some maormors, a term by which we are to understand the chief civil ruler of a district, or some bishops." We shall see, when we pursue our inquiry into a later period, that the children and grandchildren of this Celtic monarch, when they attempted to introduce new maxims of government, were opposed in Galloway and in Moray by frequent insurrections.

State of
the Church.

Looking now first to that most important and interesting point, the state of the church, we have already seen that, at the commencement of the Pictish period in 446, Christianity had been introduced into North Britain. Of the exact constitution, discipline, and orders in the early Scottish church, from the conversion of the Scots to the commencement of the Scoto-Pictish period (843), much has been written; and it is well known that the advocates of episcopacy and the supporters of presbyterianism have each endeavoured to deduce, from an examination of these remote ages, irrefragable arguments for their peculiar opinions. Into this discussion it belongs not to our plan to enter. We deal with general results, and dare not embark in controversy; but we may be permitted to observe, from the authentic monuments which still remain in our own times, and it seems difficult to avoid the conclusion, that the primitive and most ancient form of church government in Scotland was episcopal. At the memorable epoch of the union of the Picts and the Scots, we find a bishopric of Lindisferne extending far into Lothian. In Lothian itself, the religious houses of Melrose, Coldingham, Tynningham, Pefferham, and Abercorn, had been long established. In Galloway, the bishopric of Whithorn, which we have seen founded by St. Ninian, had fallen soon after the commencement of the ninth century. Looking beyond the Friths, we find that, at the same period, various religious cells had been settled by the disciples of Columba; and that not long afterwards, Kenneth Macalpin, anxious to testify his respect for the relics of this apostle of the Scots, removed his relics from Iona to Dunkeld, where he built a church, which became not only the seat of a bishop, (849), but, till supplanted by St. Andrews, the seat of the primate of the Scottish church. There is an ancient legend quoted by Spottiswood from the register of St. Andrews, which, if any credit is to be attached to it, gives the honour of founding the see of St. Andrews to Hungus king of the

Picts, who died in 833. This prince, it appears, had invaded Northumberland, and upon his return was overtaken by Athelstan, king of the West Saxons, at the head of a powerful army. "Having given order for battle against the next day," says the historian, "Hungus betook himself to prayer, spending most part of the night in that exercise. A little time before day, falling into a slumber, it seemed to him that the apostle St. Andrew stood by him and assured him of the victory, which vision being related to the army, did much encourage them. The history addeth that, in the joining of the battle, there appeared in the air a cross in the form of the letter X, which so terrified the enemies as presently they gave back, king Athelstan himself being killed. Hungus, to express his thankfulness for the victory, gave to the church of Regulus, now called St. Andrews, divers rich gifts, as chalices, basons, the image of Christ in gold, and of his twelve apostles in silver. He gave likewise a case of beaten gold for preserving the relics of St. Andrew, and restored to the spirituality the tithe of all corn, cattle, and herbage within the realm, exempting them from answering before any temporal judge; farther, he did appoint the cross of St. Andrew to be the badge and cognizance of the Picts, both in their wars and otherwise, which, as long as that kingdom stood, was observed, and is by the Scots as yet retained."¹

This extract we have given rather as a curious example of the earliest tradition as to the national emblem of the cross of St. Andrew, than from any high opinion of the authenticity of king Hungus's devotion. The following list of the Scottish bishoprics, according to the date of their foundation, is taken from Keith's Catalogue. It is to be observed, however, that in some of its dates we must regard it rather as an approximation to the truth, as far as it can be ascertained from authentic sources, than as fixing the exact years of the erection.

	A.D.		A.D.
1. See of the Isles.....	447	7. See of Ross.....	1128

Of these episcopal sees, the reader will observe, that only the bishoprics of the Isles, Galloway, Glasgow, Dunkeld, St. Andrews, and Mortlach, afterwards Aberdeen, belong to the period of which we now treat, from 843 to 1097; although the remaining sees are added, to afford to the reader some idea of their comparative antiquity. "The united kingdom of the Picts and Scots," says Chalmers, "was formed under the regimen of parishes, though neither the times nor the circumstances of this formation can be clearly ascertained amid the gloom which hangs over the Scotican church during the Scottish period. We may easily suppose that those ecclesiastical districts were gradually established subsequent to the great epoch of 843. They were pretty generally settled during the Scottish period, though they were inconveniently large. They were established by private persons, rather than by public authority. But that parishes existed during the reign of Malcolm Canmore, is certain from unquestionable records. Thus, in the charter of David the First to the monastery of Dunfermline, this monarch uses these words: *Preterea pater meus (his father was Malcolm the Third,) et mater mea dederunt ecclesiæ Sanctæ Trinitatis parochiam totam de Fotheriff.*² It seems equally certain," he continues, "that when churches were erected, parishes laid out, and parochial duties steadily performed, ecclesiastical dues must have been incident-

ally paid. In the charters of Alexander the First, and of David, tithes are mentioned as if they were familiarly known, and had been long established. It is clear that tithes were paid to the clergy during the reign of Malcolm Canmore, and probable that such ecclesiastical dues were payable as early as the commencement of the tenth century (910,) when Constantine the king, and Kellach the bishop, solemnly vowed to observe the faith, discipline, and rights of the churches.¹ During the reign of Malcolm Canmore, according to the high authority of Innes,² several national councils were held in Scotland for the establishment of ecclesiastical discipline, and the reformation of the rude and fierce manners of the people. Some extracts from the canons passed in these councils are inserted by Turgot, the confessor of Malcolm's pious consort St. Margaret, in the interesting life which he has given us of this princess.³

During this obscure period, we meet with frequent mention of an order of religious men named Culdees, who first appear in the beginning of the ninth century. They seem to have been a kind of secular presbyters or monks, the Gaelic term Culdee meaning a recluse or hermit. With the exception of the form of the tonsure and the rule of observing Easter, they professed the same rites and ceremonies as the rest of the church. It has been erroneously pretended that the Culdees rejected bishops. So far was this from being the case, that we have repeated instances of the colleges of these Celtic monks having been instituted and ordained by the bishops themselves, while they, wherever they had a college about the see, possessed a vote in the election of the bishop.⁴ Of this distinct order, we find that there existed in North Britain, during the Scottish period, religious houses at Abernethy, Dunkeld, St. Andrews, Dunblane, Brechin, Mortlach, Aberdeen, Monymusk, Lochleven, Portmoak, Dunfermline, Scone, and Kirkcaldy.⁵

It remains to say a few words on the laws, manners, and language of the Scottish period. To affect to speak with certainty upon the laws which regulated the government, restrained the crimes, or directed the succession of a fierce and barbarous people who have left no written muniments, would betray presumption and ignorance. As far as can be conjectured, we find the crown neither strictly hereditary nor strictly elective, but directed in its descent by what has been termed the law of *Tanistry*; an institution by which the person in the family of the reigning prince who was judged best qualified, whether son, brother, or even more remote relative, was chosen under the name of Tanist, to lead the army during the life of the king, and to succeed to him after his death. Chalmers has asserted, that, at this era, the tenure of land throughout the country determined with the life of the possessor; an opinion requiring some modification, as it indicates a state of barbarism even greater than is discovered by the few glimpses of light which sometimes shoot athwart this twilight of our history. By a custom which the Scots evidently brought with them from Ireland, denominated in Irish *gabhail-cine*, meaning literally family settlement, it appears, that the fathers of families divided their lands among their sons, sometimes in equal, sometimes in unequal portions, and strictly excluded females from any share in this appropriation. As to their legislative code, there seems to be little doubt that the nearest

approach we can make to the laws or usages of Celtic Scotland, must be by the study of such fragments as remain to us of the brehon laws of Ireland. "This brehon law," says Cox, "was no written law, it was only the will of the brehon or lord; and it is observable that their brehons or judges, like their physicians, bards, harpers, poets, and historians, had their offices by descent and inheritance. These hereditary judges or doctors," continues he, "were but very sad tools. The brehon, when he administered justice, used to sit on a turf or heap of stones, or on the top of a hillock, without a covering, without clerks, or indeed any formality of a court of judicature." This state of law, observes the author of *Caledonia*, may be traced among the Scots-Irish in Scotland till recent times. Every baron had his mote-hill, whence justice was distributed to his vassals by his baron bailie.⁶ There seems to be little doubt that Malcolm, from his marriage with a Saxon princess, and his frequent intercourse with the Saxon and Norman people, was an admirer of their superior civilization, and anxious to introduce their usages among his own ruder subjects. But that he succeeded to any material degree is extremely problematical; and the notion that he introduced the complicated system of the feudal law into Scotland, has been long ago exploded.

In a rapid sketch of this nature, little room can be given to any detailed description of the manners of the people during the Scottish period. The natural state of the Celtic tribes in Scotland was similar to that which we find existing among them in Ireland, namely, a state of constant war; and to those who consider how slow is the progress of improvement, and how strong the principle of imitation and tradition among a savage people, it will be no subject of wonder that we find little change produced by the lapse of centuries upon the manners of the ancient British, whether we look to Wales, Ireland, or North Britain. Their marriages, their mode of burial, their dress, their war cries, were similar. Armorial bearings, during this whole period, were unknown; seals, and coined money they had none; and it has been remarked by Chalmers, that the Gaelic people of Scotland borrowed their very terms for the several denominations of money from the Scoto-Saxon inhabitants. Thus, the Gaelic *feorling*, farthing, is from the Saxon *feorthing*; the Gaelic *peighin*, a penny, is from the Saxon *penig*.

In those rude ages of which we now write, stones of memorial were frequently employed, and many of them still remain; yet as they are found without inscriptions, and only occasionally ornamented by rude hieroglyphics, the memory of the events which they describe has perished, and the field is left open to antiquarian conjecture. Inaugural stones also were used by them, upon which not only the Irish and Scottish kings were placed on their accession to the crown; but the chiefs of septs or petty *reguli*, were accustomed on the same to take the oaths to their vassals, when they succeeded to the power of the former chief. To the same class of inaugural stones belongs, as is well known, the famous coronation stone of Scotland. Tradition reports this singular relic to have been brought from Ireland by Kenneth; it was undoubtedly carried off from Scone by Edward the First, who inserted it into a chair, which he placed before the shrine of Edward the Confessor in Westminster Abbey. It is almost impossible to speak with any precision of the state

² And here having spoken of St. Margaret, we cannot refrain, in these brief remarks on the early state of the Scottish church, from alluding to a beautiful picture preserved by this same worthy Bishop Turgot, in which he describes the love of Malcolm for St. Margaret, and the influence which the mild piety of the Saxon princess acquired over the fiery temper of her Celtic husband. "Malcolm," says he, (we use Lord Hailes's translation), "respected the religion of his spouse, was fearful of offending her, and listened to her admonitions. Whatever she loved or disliked, so did he. Although he could not read, he frequently turned over her prayer-books, and kissed her favourite volumes. He had them adorned with gold and precious stones, and presented them to her in token of his devotion. She instructed him to pass the night in prayer, with groans and tears. I must acknowledge, that I often admired the works of the divine mercy, when I saw a king so religious, and such signs of deep compunction in a layman."—Hailes, vol. i. p. 15.

Scotland
Manners.

of society in this remote period, yet a few incidental gleams of light are reflected from the lives of the early saints. Thus, in Adomnan's life of Columba, which was written only eighty years after the saint's death, we find frequent mention of houses of wattle, similar probably to those which the Constable Richard de Moreville, in a charter of the twelfth century, denominates *claiæ niscatæ*.¹ Even the abbey of Iona was built of the same rude materials. The clothing of the monks seems to have been often composed of the skins of beasts, though latterly they had woollen stuffs and linen; the first probably manufactured by themselves, the linen imported from the continent. Venison, fish, milk, flesh, and wild fowl, were the common food of the people. "The monks of Iona," says Chalmers, "who lived by their labour, cultivated their fields, and laid up corn in their garner." But it is to be recollected that the monks were every where, for ages, the improvers themselves, and the instructors of others in the useful arts. Even Iona had its orchards in the rugged times of the ninth century, till the *vikinghr*, or pirate kings, ravaged and ruined all. Looking to their shipping, we find that their little vessels were constructed by covering a keel of wood and a frame of wicker work with the skins of cattle and of deer. These were denominated *currachs*. Afterwards they were enlarged and made capable of containing a respectable crew. It was in a vessel of this description, a wicker boat covered with hides, that Columba, accompanied by twelve of his friends, embarked from Ireland, in the year 563, and landed in Iona. With these few remarks, we close the Scottish period of our national history.

SECT. IV.—*Scoto-Saxon Period.*

A.D.1097–
1306.

We have already seen, that the death of Malcolm Canmore at Alnwick gave rise to a temporary usurpation of the throne by Donald his brother, that he was expelled by Duncan, an illegitimate son of Malcolm, who had been educated at the court of William Rufus; and this Duncan having been assassinated, Edgar Atheling led an English army into Scotland, and placed Edgar, the son of Malcolm Canmore, on the throne.

Alexander
I.
A.D.1106.

Edgar's reign was brief, pacific, and of little interest; but his successor, Alexander the First, the eldest surviving son of Malcolm, was a prince of a powerful and vigorous character. From his accession to the throne, in the commencement of the twelfth century, (1106), to the death of Alexander the Third (1285), in the close of the thirteenth, a period little short of two centuries, the nation was progressive and prosperous in a degree unequalled during the whole course of its future history. Under a succession of six monarchs, Alexander the First, David the First, Malcolm the Fourth, William the Lion, Alexander the Second, and Alexander the Third, it maintained its independence against foreign aggression, and not only preserved the integrity, but extended the boundaries of its dominions. Its commerce, its manufactures, its agriculture, and all the arts which improve and humanize an ignorant and fierce people, were encouraged; and throughout this long period, in the personal characters of each of these successive princes, though varying in their shades, there was that ingredient of energy and boldness which communicated itself to their people, and maintained the nation at the standard to which each ruler in his turn had raised it.

A.D.1106–
1285.

Let us for a moment pursue our system, and like a traveller gazing from a mountain height, and noting the landmarks of a new country, endeavour to detect the leading and influential events in this division of our national history. In the character of Alexander the First, every thing seems to have been in excess; but happily the qua-

lities which were so overcharged, were most of them of the better sort. He is traditionally remembered by the epithet of the *fierce*; and though humble and courteous to his clergy, whom he deemed entitled to this homage as God's servants, not his, he was, to use the words of an ancient and authentic writer, "terrible beyond measure to his subjects." The leading event of his reign was the struggle which he maintained for the independence of the Scottish church against the pretended rights claimed, first for the independence of the Scottish Church by the see of York, and afterwards by that of Canterbury. On the election of Turgot, a monk of Durham, to the bishopric of St. Andrews (1109,) the archbishop of York insisting on his having the right of consecrating him. To this the Scottish king declared he would never agree; and a compromise having taken place, by which the point was left undecided, Alexander, on the death of Turgot, altered his ground, and chose for his successor Eadmer, a monk of Canterbury. The same right of consecration, and founded on the same ground of the alleged dependence of the Scottish church upon the primacy of England, was now advanced by Canterbury; but it was still more haughtily and peremptorily refused by Alexander. A compromise again took place. Eadmer accepted the ring from the king, and took the pastoral staff from the altar, as if receiving it from the Lord; but finding his authority weakened, and the countenance of the monarch withdrawn from him, he intimated his resolution of repairing to Canterbury for advice. This Alexander violently opposed, declaring that as long as he lived, the bishop of St. Andrews should never be subject to that see. Nor did he fail here, as in all his other enterprises, to keep his word; Eadmer remained an elected but unconsecrated bishop. At length weary of the contest, and trammelled in his usefulness, he desired permission to resign, restored the ring to the king, replaced the pastoral staff on the high altar, and returned to Canterbury. Robert, prior of Scone, was elected to fill the vacant see, and the king's determined efforts to maintain the independence of the Scottish church were crowned with success. It had continued for fourteen years, and Alexander survived its termination only a single year. He died in 1124, leaving no children by his wife Sybilla, a natural daughter of Henry I. the First, and was succeeded by his brother, David the First.

Death of
Alexander

Edgar, the brother of this prince, had, on his death-bed, bequeathed to him that portion of Cumberland which was possessed by the Scottish kings. The legacy had two good effects. It called the young prince early to the cares and labours of administration; and it removed him from Scotland to a country where he became acquainted with a more advanced civilization and with better regulated government. These advantages were not thrown away upon David. His natural dispositions were excellent; his love of justice, his capacity for labour, his sense of the national honour and independence, his affection to every class of his people, his tenderness to his children, his piety to God, were all so conspicuous in his character, that Buchanan, an author who cannot be suspected of adulation, pronounces him the perfect exemplar of a good king; and the progress made by the country during the twenty-nine years of his reign goes far to justify the assertion.

David I.
A.D.1124.

His reign was contemporary with that of Henry the First War with and of Stephen in England, and it opened with many difficulties. The question of the independence of the church was again started; and before it could be brought to a termination, the forcible seizure of the English crown by Stephen, who deposed Matilda, the daughter of Henry the First, involved him in a war with that usurper. During the life of Henry the First, David and Stephen had sworn

¹ Liber de Melrose, vol. i. p. 95.

Scotland. to maintain the right of Matilda; and the Scottish monarch, in obedience to his oath, invading England, compelled the barons of the northern portion of that kingdom to swear fealty to this princess. His efforts however were more honourable than successful; and after a war which lasted three years, David was ultimately defeated in the great battle of the Standard, fought on Cutton Moor, in the neighbourhood of Northallerton. Peace was now concluded, and the terms to which Stephen consented, indicate that, although defeated, the Scottish king was but little humbled.

Battle of the Standard. A.D. 1138.

The earldom of Northumberland, with the exception of the two castles of Newcastle and Bamborough, was ceded to Prince Henry, David's eldest son. As an equivalent for these fortresses, lands were granted to him in the south of England; the barons of Northumberland were to hold their estates of Henry the Prince of Scotland, reserving their fealty to Stephen; and in return, David and all his people became bound to maintain an inviolable peace with England.

Character of David I. The remaining years of the reign of this wise monarch were pacific and prosperous. The war had convinced him that the English were far superior to his people in arms and discipline; it had been undertaken in fulfilment of his oath to Henry, not from any love of conquest, and having satisfied his conscience, he devoted his life to the arts of good government. "During the course of his sage administration," says Lord Hailes, "public buildings were erected, towns established, agriculture, manufactures, and commerce promoted. The barbarities of his people in their invasions of England, had affected him with the deepest anguish, and believing that religion was the only agent which could humanize and improve the savage multitudes whom he had led, but could not restrain, he endowed the church with new privileges, enriched it with extensive grants of land, founded various bishoprics, built many monasteries, and exhibited in his own person so fine an example of royal greatness, chastened and purified by Christian humility and devotion, that it could not fail to have the best effects upon his people."

Death of Prince Henry. A.D. 1152. Towards the close of his reign, it was his misfortune to lose his eldest son, Prince Henry, just as he had reached manhood, and exhibited many of the excellent qualities of his father. The blow sunk deep into his heart; but David's first care had been for his people, and he roused himself to provide for the pacific succession of his grandson, Malcolm, a child in his twelfth year. By his orders, this boy, the son of Prince Henry, was carried in a progress through his dominions, to receive the homage of the barons and the people, and was solemnly proclaimed heir to the crown. Having performed this wise but mournful duty, the aged king within a year followed his son to the grave. It is a remarkable and beautiful circumstance, that he was found dead in an attitude of devotion. "His death had been so tranquil," says Aldred, who knew him well, "that you would not have believed he was dead. He was found with his hands clasped devoutly upon his breast in the very posture in which he seems to have been raising them to heaven."

Malcolm IV. The reign of Malcolm the Fourth, which lasted only twelve years, offers little for our observation. It began with those evils which so invariably attend a minority; war without, and insecurity within the kingdom. Somerled the thane of Argyle, strengthened by the naval powers of the Isles, invaded Scotland, and for some years continued to harass the country by repeated attacks, which at length terminated in an amicable agreement. The transactions of Malcolm with Henry the Second of England impress us with an unfavourable notion of this young prince. It had been a promise of the English monarch made to David the First, in 1149, that if he succeeded to the crown of England, he

would cede to Scotland for ever the territory between the Tyne and the Tweed. Instead of insisting on this, Malcolm, overreached by the superior sagacity of Henry, or betrayed by the treachery of his councillors, abandoned to England his whole possessions in the northern counties, and received in return the honor of Huntingdon; a measure which created universal discontent in the nation. These feelings of disgust were imprudently increased by an expedition of the young prince into France, where he joined the army of Henry, claimed from him the distinction of knighthood, and outraged the feelings of national jealousy, by forgetting his station as an independent prince, and fighting under the banner of the English monarch. A deputation from the Scots was sent into France to remonstrate against this conduct, nor did they hesitate in bold language to reproach their king for the desertion of his duty. Galloway rose into rebellion; the inhabitants of Moray about the same time threw off their allegiance; and Somerled the thane of Argyle invaded the country with a formidable fleet. Although the obstinacy of the king had brought these disasters upon himself, his energy and decision met and overcame them. He hurried from France, conciliated his nobles, invaded and subdued Galloway, repulsed Somerled, and after suppressing the rebellion in Moray, adopted the extraordinary measure of dispossessing its ancient inhabitants, compelling them to settle in more distant parts of his dominions, and planting new colonies in their room. These energetic measures were his last, for he died immediately after, at an early age, and was succeeded by his brother William the Second, son of Henry, prince of Scotland, and grandson of David the First.

The administration of this prince presents us with the longest reign in the range of Scottish history, extending from 1165 to 1214, nearly half a century. In this protracted division, the most important event was, the disgraceful surrender of the national independence to Henry the Second in 1174, and its recovery by William in 1189. Both transactions require our serious notice. It was the weakness of William to be guided by impulse. Smitten with admiration for the warlike qualities of Henry the Second, and uninstructed by the misfortunes of his predecessor Malcolm, he first courted this prince, and being disappointed in his object of procuring from his justice the restitution of Northumberland, he imprudently defied him. War ensued; and the king of the Scots having advanced with his army to Alnwick, was surprised, made prisoner, and shut up in the castle of Falaise in Normandy. His impatience under captivity, and the longing of the barons and clergy for their king, led to a pusillanimous treaty, which will ever remain a blot upon the national honour. With consent of his barons and clergy, given at Valogne on the 8th of December 1174, William agreed to become the liegeman of Henry for Scotland, and all his other territories; to deliver up to the English monarch the castles of Roxburgh, Berwick, Jedburgh, Edinburgh, and Stirling; to give his brother David and some of his chief barons as hostages, and to receive in return his liberty. In this treaty, it is remarkable, that while little care was shown as to the independence of the people, a prudent, and, as it has been well denominated, a memorable clause was introduced, which left entire the independence of the Scottish church; and this clause, the bishops and clergy took the first opportunity of asserting before the Papal legate in a council held at Northampton (1176).

On his return to his dominions, William appears to have devoted himself with much energy and success to the cares of government. His dominions were weakened and distracted by repeated insurrections in Ross and in Galloway. In these wild and remote districts, the native chiefs claimed almost a royal sway; and the people, ferocious in their habits, and jealous of all intercourse with England, were ready, upon the slightest provocation or encouragement, to

Scotland.
Malcolm IV.
A.D. 1153-1165.

the Lion.
A.D. 1165-1214.

Returns to Scotland.

Scotland. rise in rebellion. A pretender to the crown also appeared in Galloway, in the person of Donald, the grandson of Duncan, commonly called the bastard king of Scotland. William the Lion. This adventurer having seized Ross, and wasted Moray, William led an army against him; nor was it till after a desperate struggle that Donald fell near Inverness, and by his death restored tranquillity to the country.

The Scottish Church declared independent. A.D. 1188. We have already seen how firmly the Scottish church had renounced the idea of any dependence upon the metropolitan sees of York or Canterbury; we have adverted to that careful reservation of their rights at the moment when the king and the nobles bartered away what was not theirs to give, the national independence. In this resolute conduct the clergy were supported by the king; and in 1188, Clement the Third pronounced a solemn decree, by which he declared the "church of Scotland to be the daughter of Rome, and immediately subject to her; and that to the Pope alone, or his legate *de latere*, should belong the power of pronouncing any sentence of excommunication against that kingdom."

The kingdom recovers its independence.

This important declaration was soon followed by another event still more memorable, in which the kingdom recovered its independence. On the death of Henry the Second, Richard Cœur de Lion, his successor, then intent upon collecting money for his expedition to the Holy Land, invited the king of Scotland to his court, and upon William's engagement to pay to him the sum of ten thousand marks, agreed to restore his kingdom to its independence, reserving the homage formerly due by the Scottish kings for the lands which they held in England. The instrument by which this transaction was completed, declares, that Richard had delivered up to William king of Scots, his castles of Roxburgh and Berwick, had granted to him an acquittance of all obligations which had been extorted from him by Henry the Second, in consequence of his captivity, and had ordained the boundaries of the two kingdoms to be re-established as they existed at the date of William's imprisonment. The Scottish king was at the same time put in possession of all his fees in the earldom of Huntingdon, and all the charters of homage done to Henry the Second by the Scottish barons were delivered up, and declared to be cancelled for ever. We are to ascribe it to the wise regulations of this treaty, and the fidelity with which they were observed on both sides by its authors and their successors, that for a century after its date, there occurred no national quarrel or hostilities between the two countries. The remaining portion of the reign of William demands little notice. During the latter years of it, the succession of John to his brother Richard the First threatened to dissolve the pacific relations between the two countries; but war was happily averted, and the Scottish monarch reserved his energies for the pacification of his own realm, disturbed by a rebellion in the northern counties. In 1214, the king died at Stirling, after a reign of forty-eight years, the longest, as already stated, in Scottish history. His name of William the Lion was probably owing to the circumstance, that, before his time, none of the Scottish kings had assumed a coat armorial. The Lion rampant first appears upon his shield.

Alexander II. A.D. 1214

William was succeeded by his son Alexander, a youth of seventeen, to whom the Scottish barons had sworn homage in 1201, and who was one of the wisest of our kings, whether we regard the justice of his administration, the seasonable severity with which he subdued all internal commotions in his kingdom, the firmness exhibited in his maintenance of the rights of the church, or the wisdom, forbearance, and vigour which marked his policy towards England. His reign was one of constant action, and full of incident. It commenced with his joining the English barons who resisted the tyranny of John. This conduct drew down upon him and his kingdom a sentence of excommunication (1210); but the papal terrors appear to have been little dreaded at this time; and in 1218, Honorius not only abrogated the

sentence pronounced by his legate, but confirmed the liberties of the Scottish church.

On the accession of Henry the Third to the English throne, Alexander, who was occupied with quelling the repeated insurrections in the northern parts of his dominions, showed every disposition to cultivate amity with England; and his marriage to the princess Joanna, sister of Henry, had a favourable effect in strengthening the ties between the two monarchs.

One of the striking features which mark the reign of this monarch, is the gradual increase that is to be observed in the power of the nobles, and the corresponding decrease in the power of the crown; but if this had injurious effects upon the general prosperity of the kingdom, and distracted it by internal private feuds, it encouraged a feeling of independence, and fostered that warlike spirit, which proved the best safeguards against the encroachments of their more powerful neighbours. This was strikingly shown on the occurrence of a rupture between England and Scotland in 1244. Some time before this, Alexander had claimed from Henry, in right of inheritance, the counties of Northumberland, Cumberland, and Westmoreland; and although the English king did not grant him his full demand, he admitted its justice, by transferring to him an equivalent in certain lands, which he accepted in full of all claims. For these lands the Scottish king did homage; and both monarchs remained on friendly terms for some years, when jealousies suddenly arose, and Henry, alleging that homage had been unjustly withheld, led an army against Scotland. Under these threatening circumstances, the Scottish king, although he had recently experienced the resistance of his nobles to his personal requests, found himself strongly supported by the same barons against the meditated attack of England. They raised in a short time an army of a hundred thousand foot, and a thousand horse, and this demonstration of the national strength had happily the effect of restoring peace without bloodshed. It is worthy of notice, that when a papal legate visited Scotland under this reign, and held a provincial council in the capital, the king manifested the same jealousy of such a proceeding as had been exhibited by his predecessors. He seemed afraid lest the admission of a papal messenger, whose message regarded England alone, should be deemed derogatory to the independence of the Scottish church; and although, at the request of the nobility of both countries, he consented to his coming into the kingdom, he declined a personal meeting, and stipulated that this permission should not be drawn into a precedent.

Having engaged in a maritime expedition against Angus of Argyll, one of those petty island chiefs, whose dubious allegiance, in those remote times, oscillated between Norway and Scotland, Alexander had conducted his fleet as far as the Sound of Mull, when he was seized with a fever, and died in a small island there named Kerraray, in the 35th year of his reign. He was succeeded by his son, Alexander the Third, a boy in his eighth year; and the kingdom, which had enjoyed under his father's wise and vigorous administration, an uncommon degree of prosperity, became immediately exposed to the many evils of a minority. Two parties divided the nobility; the one led by Walter Comyn, earl of Menteith, the other by Durward the high Justiciar; and Henry the Third secretly wrote to the Pope, requesting him to interdict the coronation of the young king. Scotland, he said, was a fee of England, Alexander his vassal, and his permission as superior had not been obtained. The Pope appears to have rejected his demand with promptitude, as derogatory to the rights of a sovereign Prince; and the ceremony of the coronation was performed at the abbey of Scone, the coronation-oath being read first in Latin, and afterwards in Norman-French.

Alexander soon afterwards, in fulfilment of a former treaty,

Scotland. espoused Margaret, the youthful daughter of Henry, at York, and exhibited a spirit and intelligence superior to his years, in refusing to pay homage for his kingdom of Scotland. "I came," said he to the artful monarch who made the proposal; "I came into England on a joyful and pacific errand, not to answer to an arduous question, which belongs to the states of my kingdom." He at the same time made no objection to take the oath of fealty for the lands which he held in England.

Intrigues of Henry III. with Scotland. Defeated in this attempt to overreach a minor sovereign, Henry commenced a series of intrigues with the Scottish nobles, with the object of obtaining an entire control over the affairs of the sister kingdom; and the country was divided and distracted by two factions, the one acting under English influence, and the other more honestly contending for the freedom of their prince and the independent administration of the government. These scenes of civil faction and foreign interference continued till the monarch, having arrived at manhood, and developing a character of much energy and judgment, took the reins into his own hand, and compelled his nobility to respect the laws and support his measures.

Haco, king of Norway, defeated at Largs. A.D. 1263. Scarcely had this happy change occurred, when the kingdom, which had already suffered from the vicinity of the fleets of Norway, was threatened with invasion by Haco, one of its most warlike princes. The dispute which led to this menace originated in a circumstance already noticed; the precarious homage paid by the petty piratical chiefs of the Western Isles, who, as circumstances pressed on the one side or the other, acknowledged a feudal dependence on Scotland or on Norway. To support them in their independence on Alexander, Haco made a descent on the western coast of Scotland with a mighty fleet, but sustained a signal defeat at Largs, and on his return with the shattered remains of his ships, sickened and died at Orkney. The results of this victory were highly favourable to Scotland. It fixed the chiefs of the Western Isles in their allegiance, secured to Alexander the homage of the king of Man, and convinced Norway that Scotland was not to be so easily subdued or overawed as its piratical princes had anticipated.

Death of Alexander III. A.D. 1255. The remainder of this reign was prosperous, as far as the circumstances of the kingdom are considered, but unfortunate for the monarch, who found himself suddenly deprived by death of all his children. His eldest son, Alexander, died soon after his marriage, and his only daughter Margaret, the wife of Eric, king of Norway, was cut off in childbed, leaving an infant daughter, Margaret, commonly called the Maiden of Norway, the heiress of the Scottish throne. These calamities induced the king, who was a widower, to make a second marriage. Having selected Ioleta de Coney, daughter of the Count de Dreux, the nuptials were celebrated at Jedburgh; and the nation, under a wise monarch still in the prime of life, flourishing at home and at peace abroad, looked forward to a long season of prosperity, when all its hopes were overcast in a moment. Alexander, when riding in a dark night, on the brink of a dangerous rocky ledge near Kinghorn, was precipitated from the top to the bottom, and killed on the spot.

Death of the Maiden of Norway. The death of the king was deeply lamented, and not without cause, for he left the kingdom in most difficult circumstances, exposed to the ambition and attack of Edward the First, one of the ablest princes who had ever reigned in England, and its happiness at home dependant upon the precarious life of an infant. To fill the cup of Scotland's calamity, this child, Margaret, the Maiden of Norway, when on her passage from that country to take possession of her throne, sickened and died in Orkney; and on her death arose that celebrated competition for the Scottish crown, which threatened to plunge the kingdom into all the miseries of civil war.

The moment was favourable to the designs of Edward Scotland. the First, who determined to make himself master of Scotland. While in that country the various competitors collected their forces and prepared to support their claims, the English monarch having given orders for assembling the strength of his kingdom by a certain day, invited the nobility and clergy of Scotland to meet him at Norham, for the purpose of deliberating upon the succession to the crown. It has been made a subject of dispute, whether Edward was invited by the Scottish people to be umpire in the contest for the crown, or whether he proposed himself as judge, and the subject is involved in some obscurity. It is by no means improbable, that English intrigue and a regard to their own interest, had induced some of the competitors, if not to invite, at least most readily to accept the mediation of the English monarch; but it is equally true, and the point is of far greater importance, that there is no evidence to prove that there was any invitation of this kind, either by the people of Scotland, or even by a majority of its nobles and clergy. Be this as it may, Edward the competitors for the crown, with a large proportion of the nobility and clergy of Scotland, accepted the mediation of Edward, and met this monarch at Norham, (May 1291).

Of these claimants for the crown the two principal were John Balliol and Robert Bruce. It was quite apparent that the question lay between them, the rights of the other competitors being evidently inferior to theirs. The title of these two chiefs arose out of the circumstance, that on the death of all descendants of Alexander the Third, the crown reverted to the descendants of David, earl of Huntingdon, brother of king William the Lion. This David left three daughters, Margaret, the eldest, who married Alan, lord of Galloway; Isabella, the second, who married Robert Bruce, father to the competitor Robert Bruce, lord of Annandale; and Ada, the third daughter, who married John de Hastings. It was evident, therefore, that the question lay between Balliol and Bruce. Balliol pleaded that he was entitled to the crown as the descendant of the eldest daughter, being great-grandson to David, earl of Huntingdon. Bruce admitted that he sprung from the second daughter, but contended that, being grandson of the earl of Huntingdon, and therefore a degree nearer, his claim was superior.

Edward's scheme against the independence of Scotland Conduct of Edward I. was now ripe for execution; and announcing his determination to give a just decision, he, to the dismay of many present, required the Scottish barons to swear fealty to him as their Lord Paramount. It was in this character alone, he said, that he was entitled to give, and as such alone that he would pronounce, a judgment. The scene which now ensued was a humiliating one. The right of Edward was admitted; and Bruce, Balliol, the remaining competitors, the barons and the clergy, set their hands to an instrument, in which they acknowledged that the English king was feudal superior of Scotland. There can be little doubt that they knew this claim of Edward to be untenable upon any ground of truth or justice, but they saw it ready to be enforced by a determined prince at the head of the whole strength of his dominions, and they did not dare to resist it. Edward, accordingly, having received their oaths of homage, proceeded to investigate the contending claims, and awarded the crown to John Balliol.

It was probably part of the plan of the English monarch He invades Scotland. to quarrel with his vassal king. It is at least certain, that he availed himself of the earliest appearance of spirit and resistance in this unfortunate prince to summon him, in terms of reproach and indignity, to his court in England, and at last goaded him and his people into what he termed rebellion. In the war which ensued, Edward found it an easy matter to overrun a kingdom unprepared to resist so formidable an enemy. The town of Berwick was carried by storm;

Scotland. Dunbar, the key of the borders, surrendered; Balliol was taken prisoner and sent to the Tower; while the English prince concluded what he deemed the conquest of Scotland, by removing from Scone to Westminster the sacred stone upon which the long line of its kings had been crowned and anointed. But at this sad moment Scotland, which in vain looked for a deliverer amongst its feudal nobles, found one in a man of far inferior rank.

Rise of Wallace. William Wallace was the son of Sir Malcolm Wallace, who held the estate of Ellerslie, near Paisley. Having been outlawed by the English for an alleged murder, committed on one by whom he had been grievously injured, he fled into the fastnesses of his country, and assembling round him a small band of followers, who were weary of their servitude, commenced that kind of predatory warfare, which led from one success to another, till he saw himself at the head of a formidable force. With this he boldly descended into the low country, and after having defeated the English in the sanguinary battle of Stirling, was soon after chosen Governor of Scotland. This title he only accepted as acting in the name of John Balliol, whom he had always acknowledged as his hereditary king. Into the exploits and career of this great man it is impossible, within our limits, to enter; but making every allowance for the passionate admiration of his countrymen, and regarding him as reflected in the cold glass of history, rather than invested with the brilliant hues of romance, there will still be found all that constitutes a heroic character, if the accomplishment of the greatest results with the most confined means, an entire devotion to his country, a contempt of power for its own sake, unextinguishable hatred of oppression, and a personal courage which nothing could shake for a moment, were ever entitled to such an epithet.

Battle of Falkirk. It was however impossible for Wallace, with all his great qualities, to reconcile the Scottish nobles to his envied elevation, or to compose the feuds and jealousies which divided and weakened their efforts. Edward, who had been absent in Flanders when his officers were defeated at Stirling, hurried back to England, and once more invading Scotland at the head of an immense army, encountered and defeated Wallace in the battle of Falkirk. The result of this victory was the temporary subjugation of a country, whose allegiance expired the moment its invaders retired. Wallace voluntarily resigned the office of Governor, Robert Bruce and John Comyn were chosen Guardians, and for five years the war was continued with various success; but Edward, who in this interval had thrice invaded the kingdom, by these unceasing efforts and superior numerical strength, at last subdued the spirit, and appeared to have completed the conquest of this devoted people. The Guardians submitted and were pardoned; sentence of outlawry was pronounced against Simon Fraser and the few followers of Wallace who still held out; and at last this great chief himself was betrayed into the hands of the conqueror, and executed at London. It was at this crisis, which seemed to seal for ever the fate and liberty of the Scottish people, that a deliverer arose in the person of Robert Bruce.

Wallace executed.

SECTION V.

A. D. 1306 to 1436.

Reign of Robert Bruce. Nothing could be more extraordinary, or apparently more unpropitious to the cause of freedom, than the circumstances which led to this great result. Robert Bruce, earl of Carrick, and grandson of the competitor for the crown, had acted a dubious and interested part during the years that Wallace, and the few patriotic barons who adhered to him, made their stand for the independence of their country. He inherited, with vast landed estates, the right to

the crown possessed by his grandfather; but, had he urged his claim, it might have been at the risk of the forfeiture of these possessions, which made him one of the most powerful barons in Scotland; and, although, in his early career, we can detect occasional outbreaks of the patriotic feeling, he preserved his allegiance to Edward the First, and appears to have been treated with confidence by that monarch.

The injuries inflicted on the country seem at last to have aroused both Bruce and Comyn, and they formed a secret agreement to rise against the English. But Comyn's heart failed him. He betrayed the purpose to Edward, and meeting Bruce, who had been made aware of his treachery, in the church of the Grey friars at Dumfries, that proud baron reviled him as an informer, and stabbed him to the heart on the steps of the high altar. He was instantly proclaimed a traitor by Edward, excommunicated as a sacrilegious murderer by the Pope, a price set upon his head; and from the first and most influential noble in the kingdom, he felt that he must either assert his right to the crown, and trust to his sword for its defence, or be content to sink into the condition of an outlaw and a fugitive. His decision was instantly taken. He rode with his little band to Scone, and was there solemnly crowned; but being aware of the advance of an English army, he hastily concentrated his forces, and after ravaging Galloway, marched against Perth, then in possession of Edward.

But the early portion of Bruce's career was disastrous; and those military talents, which afterwards conducted him through a course of unexampled victory, were nursed amid incessant defeat and hardship. He was put to flight at Methven, his small army dispersed, and he himself driven an almost solitary wanderer through Lennox and Kintyre, to seek an asylum in Rachrin, a little island on the northern coast of Ireland. Here he remained during the winter, unaware of the execution of his faithful followers, who had fallen into the hands of Edward; of the imprisonment of his queen and daughter, and the extraordinary severity with which the English monarch seemed determined to rivet the fetters upon his native country.

In the spring he passed over from Rachrin to Arran, accompanied by his brother Edward Bruce, Sir James Douglas, and about three hundred men. His own castle of Turnberry, on the coast of Carrick, was then occupied by Lord Percy, an officer of Edward. Bruce attacked it, put the English garrison to the sword, and, after a variety of minor enterprises, in which, although often repulsed, he and his followers gained experience and confidence, he ventured, although at the head of only six hundred spearmen, to meet the earl of Pembroke, with three thousand cavalry, at Loudon Hill, (May 1307). The result of this conflict, owing to the admirable dispositions of Bruce, was the entire defeat of the English; and from this point, the crisis of his fortune, to the hour when the liberty of his country was for ever secured on the field of Bannockburn, the career of this extraordinary man presented an almost continued series of success.

It was perhaps fortunate for Scotland that he was opposed, not by Edward the First, who had died when on his march to Scotland, (1307), but by his son, Edward the Second, a prince of far inferior talent; yet the military resources of England were so formidable, and the barons who wielded them such experienced leaders, that Bruce, who had to struggle against domestic enemies, as well as foreign invasion, may well be praised for the admirable judgment with which he wielded the strength of his little kingdom. It was his policy to avoid a general battle, and to starve and distress the formidable armies which England repeatedly sent against him, by wasting the country, retiring slowly before his enemies into the woods and fastnesses, and when they were compelled by famine or the season to retreat, by hanging on their rear and cutting them off in detail. Convinced that, from the

poverty of Scotland, it was in vain to attempt to rival the mounted chivalry of England, he turned his whole attention to the formation and discipline of his infantry. They were armed with a spear eighteen feet in length, a sword and battle-axe at their girdle, a short cut-and-thrust dagger, a steel bonnet, and a back and breast-piece buckled over a tough leather jerkin. They were trained to form sometimes in squares, sometimes in circles, more or less deep, according to the nature of the ground and of the service. Such was the main army of Bruce, his pikemen; but after he had restored peace and security to his kingdom, and began in his turn to act upon the offensive, he often employed the only kind of cavalry which Scotland could raise, the border prickers, who, lightly armed, mounted on hardy little horses, and carrying as their provisions a bag of meal slung at their saddle-bow, darted upon the richest districts of England, or stripped them of their wealth, and scoured like a whirlwind across the border, ere the force of the country could be raised in its defence.

Battle of
Bannock-
burn.
A.D. 1314.

To pursue the details of his obstinate contest with England, is impossible. It was during the first years a war of defence, in which Bruce struggled for existence. This secured, it became aggressive; but his efforts were confined to the recovery of his dominions out of the hands of those Scottish barons who had embraced the service of the enemy, or his castles from the English governors to whom they had been entrusted. At last, when Edward the Second, at the head of an army a hundred thousand strong, composed of the flower of his kingdom, and led by his most experienced officers, had penetrated into the country, Bruce found himself driven from his favourite maxim, and compelled to hazard a battle. On the field of Bannockburn, near Stirling, thirty thousand Scottish foot, and five hundred horse, led by the king in person, and under him commanded by Douglas, Randolph, and the Steward of Scotland, encountered and entirely defeated the formidable array of England. Edward fled from the field to Dunbar, and the broken remains of his army, in dispersed bodies, made their retreat in much disorder into England, (June 24, 1314).

In this memorable victory it may be said, without exaggeration, that a lesson in the history of liberty was taught, not only to Scotland, but to the world; to every people who have felt the misery of servitude, or tasted the sweets of freedom. It proved that a country may be, as Scotland was under Edward the First, brought by oppression and cruelty to the very brink of despair; its cities sacked, its fields laid waste, till famine was the consequence; its best leaders executed or imprisoned, its hearths left desolate, its very offerings of praise proscribed, and its refuge in religion attempted to be cut off; but that, till exterminated, a free-born people cannot be said to be subdued.

Effects of
the victory
at Bannock-
burn.

The immediate effects of this great victory upon the spirit of the respective countries, were not less remarkable. It convinced the Scots, that, with a good heart and skilful leaders, their squares of infantry, with their long pikes, were a match for the English horse, however superior in arms and numbers; it taught the king, that what he had most to dread was the discharge of the English bowmen; and admonished him, that, however complete had been the defeat, however glorious the consequences of the victory, his favourite military maxim, to avoid a general battle, was still his best and safest course. It affords a striking view of the character of this great man, that his success at Bannockburn led neither to presumption, nor, much as he had suffered, and deeply as he had been injured in his tenderest relations, to a cruel retaliation. On the contrary, it was followed up by Bruce with an immediate proposal for

peace; but he would consent to treat only on the footing of an independent king, and the offer was rejected.

From 1314 to 1328, an interval of nearly fourteen years, the war was continued with almost uninterrupted success on the part of the Scots; while a series of reverses were endured by England, which are chiefly to be ascribed to the pusillanimous character of the monarch, and the great military ability not only of Bruce, but of the officers whom he had trained, Sir James Douglas, Randolph earl of Moray, the young steward of Scotland, and many others. It may convey some idea of Bruce's incessant occupation in the field, when it is mentioned, that during this interval, England was twelve times invaded, either by the king in person, or by his officers, its border counties were exposed to ravages, and on frequent occasions the fires which marked the Scottish march were seen burning beside the gates of York; nor were the Scottish king's proposals for a peace accepted, till the English districts, which were compelled to purchase safety by the payment of a heavy tribute, threatened in their misery, to throw themselves into the arms of Scotland. At last, on the first of March 1328, an English parliament assembled at York. Bruce was acknowledged king of Scotland, Scotland itself recognised as a free and independent kingdom, and peace established, after a sanguinary war of twenty years.

Robert
Bruce.
A.D. 1314-
1328.

This great consummation was not long survived by him to whom, under God, the result was chiefly due. The king, whose constitution had been broken by the fatigues and exposure of his early life, began to droop soon after he saw the liberty of his country permanently established; and he died at Cardross on the 7th of June 1329.

Death of
Bruce.
A.D. 1329

The death of Bruce was a severe trial to Scotland. His only son David, who succeeded him, was a boy of six years old; and while the nation was thus exposed to all the evils of a long minority, Edward the Third, one of England's most warlike monarchs, was just commencing his career, which soon developed uncommon talents, and great ambition. Randolph indeed, who was chosen Regent, and the good Sir James Douglas, with other veteran officers, still remained; but Douglas was slain in Spain, whither he had proceeded on his way to Jerusalem with his master's heart; and the earl of Moray only survived the death of Bruce for three years. To add to these calamities, the monarchs who successively filled the Scottish throne, and on whose personal character, in these rude times, much of the success and vigour of the government depended, were little similar to their great predecessor. From the death of Bruce till the reign of James the First, the first prince who in any measure was worthy of a comparison with him, a period of nearly a century elapsed,¹ in which the sceptre passed into the hands of three princes, David the Second, Robert the Second, (the first sovereign of the house of Stewart, being the son of the Steward of Scotland, by Marjory, Bruce's only daughter,) and, lastly, Robert the Third. Contemporary with these Scottish princes were Edward the Third, Richard the Second, Henry the Fourth, and Henry the Fifth, all, with one exception in Richard, wise, warlike, and fortunate monarchs. The odds, therefore, were infinitely against Scotland, a country far inferior in its population and resources to England, and torn by domestic feuds; and yet against reiterated attacks it maintained the contest for its liberty. Unable to descend into minute detail, we take a summary of the larger portion of this calamitous interval of Scottish history, from another work. "A period of sixty-four years elapsed between the death of Robert Bruce and the birth of James the First, during which time, although torn by anarchy and domestic faction, the country maintained a remarkable struggle for its liberty. It

David II.
Regency of
Randolph.

¹ We date not from the birth of James, but his return from captivity in England. It may be proper to mention, that the authorities for this sketch, from Alexander the Third to the reign of Mary, are the same as those followed by Mr. Tytler, in his History of Scotland.

Scotland. was in this period, eight times invaded by a foreign force ; it was betrayed and deserted by David the Second, the unworthy son and successor of Bruce ; it saw, on many occasions, the most powerful of its nobles enlisted under the banner of its enemies ; it had to struggle against the military genius and political talents of Edward the Third, and Henry the Fourth and Fifth ; and yet, with limited resources, and divided councils, so tenaciously did the people cling to their liberty, that, though sore oppressed, they were never conquered. Amid almost constant war, and its dreadful accompaniments, famine and the pestilence, they still preserved their freedom, preferring the prospect of living in a country reduced by repeated invasion to a solitude or a desert, or even the last alternative of being totally exterminated, to the most flattering offers of being united to England, when coupled with the condition that they should renounce their national independence.¹ We have above alluded to the degeneracy of David the Second, whose long reign of forty-two years was divided into a minority, the greater part of which was passed in France ; a captivity in England, the result of his calamitous defeat in the battle of Durham ; and a train of subsequent reverses all occasioned by his headstrong character and devotion to his selfish pleasures. But the darkest stain upon David, was his intrigues with Edward the Third, in which he hesitated not to sacrifice the independence of the country, to swear homage to the English prince for his kingdom of Scotland, and even to propose to his parliament, that the order of succession solemnly settled by his heroic father, should be altered in favour of an English prince. It is needless to say that so degrading a proposal was indignantly repelled, and that the death of the prince who had offered the insult was regarded as a national deliverance.

Robert II. In Robert the Second, who succeeded him as the first of the house of Stewart, and his son, Robert the Third, the nation, though still exposed to the repeated attacks of England, experienced a short breathing time, owing to the death of Edward the Third, and the incapacity of Richard the Second ; but neither of these Scottish princes possessed the vigour or the talents requisite to wield the sceptre with success, in the midst of the difficulties by which they were surrounded. The second Robert came to the crown when age had chilled his vigour ; and his son and successor, Robert the Third, was of too indolent and gentle a character to hold his part against a fierce feudal nobility, led by his brothers, the Earls of Fife and Buchan, the first a man of great ambition, the second a monster of crime, who gave himself up to every species of lust and rapine, and has been traditionally remembered as "the Wolf of Badenoch."

James I. All this led to great disorder. The king, unwilling to burden himself with the cares of government, devolved the administration upon his son, the duke of Rothesay, a young man of violent passions, though of considerable ability, who had made himself particularly obnoxious to his uncle, the earl of Fife. This led to a fatal collision. Fife, whose authority was increased by his being made duke of Albany, proved too strong for the young prince. His father, the king, was persuaded that the excesses of his son required restraint, and the unhappy youth was hurried to Falkland, and shut up in a dungeon, where he was intrusted to the care of two ruffians, who starved him to death. It was at first reported that he had been cut off by a dysentery ; but the horrible tale of his sufferings soon after transpired. "A poor woman in passing through the palace garden, had been attracted by his groans, and had found means to support him by thin cakes which she slid into the grated window of his prison, and it is said by her own milk, conveyed through a reed ; but she was detected, and put to death by his keepers ; and after fifteen days, the body of the miserable

captive was found in a state too shocking to be described. Scotland. In the extremities of hunger, he had gnawed and torn his own flesh."² Robert, depressed by this calamity, and incapable of exertion, committed the whole cares of the government to the duke of Albany ; and the power of that daring man was increased by another event which completely broke the spirit of the king, and was probably the cause of his death. This was the seizure by the English of his eldest son James, then a youth in his fifteenth year, and on his passage to France. The consequences were very fatal to the country. The prince was carried to the Tower ; the father did not long survive the captivity of the son ; and on his death, which took place in 1406, his brother, the duke of Albany, succeeded to the prize which had long been the object of his ambition, the undisputed regency of the kingdom.

The young king, James the First, was a captive, and Henry the Fourth knew too well the value of the prize to part the Duke with him. For nineteen years he was detained in England ; and, during this long interval, Albany became the uncontrolled governor of Scotland. It has been suspected that the intrigues of this able and unprincipled man with the English monarch, had led to the seizure of the young king. That they prolonged the period of his captivity, there can be no doubt.

It was clearly the best policy of the regent to cultivate peace with England, and to conciliate Henry the Fourth, as this prince could at any time put a termination to his authority, by restoring James to his kingdom ; and the same desire to retain the power which he had so nefariously usurped, induced Albany to cultivate the friendship, and overlook the crimes and excesses of the great feudal barons. All this led to dreadful confusion in Scotland, which, although freed for a time from the incessant invasions of its more powerful neighbour, was torn by private war, whilst the lives and property of its people were exposed to the attack of every unprincipled feudal baron who sheltered himself under the protection of the regent.

This miserable state of things was at length terminated by the return of James to his dominions ; a prince whose character presented a striking contrast to that of his father and grandfather. During the nineteen years in which he had been unjustifiably detained in that country, he enjoyed advantages which almost repaid him for his captivity. Henry the Fourth, a prince who well understood the art of government, had made it his generous care that James should receive an excellent education ; and he had the advantage of being instructed in war, by accompanying his victorious successor, Henry the Fifth, to France. On his return to his own dominions, he was in the prime and the vigour of manhood. His character, formed in the school of adversity, was one of great power. He found his kingdom a scene of lawless excess and rapine ; a condition to which it had been reduced from the want of a firm hand to restrain oppression and enforce the laws. Since the death of Bruce the power of the aristocracy had been on the increase, while that of the crown had proportionally lost ground, and fallen into contempt. His object, as can be clearly discerned through the history of his brief reign, was to restore the kingly authority, to rescue the commons from oppression and plunder, to give security to property, encouragement to the industry and pacific arts of his people, and to compel his barons to renounce their ideas of individual independence, and become good subjects.

The regency of Albany, his uncle, and of his son Murdoch, who had succeeded him, was naturally and justly regarded by James as little else than a long usurpation. He was mortified that Albany, against whom, as the murderer of his brother, he entertained the deepest resentment, should have escaped his merited punishment ; and the royal

¹ Life of James the First, pp. 203, 204, in Lives of Scottish Worthies.

² Lives of Scottish Worthies, vol. ii. p. 242.

Scotland. vengeance fell with a proportionably heavier force upon Murdoch, his son and successor; nor is it possible to deny that James's retribution was cruel and excessive. Murdoch, the duke of Albany, his two sons, the earl of Athole, and Alexander Stewart, with his father-in-law, the earl of Lennox, a venerable nobleman, eighty years of age, were tried, condemned, and executed. James, the duke's youngest son, having escaped, collected a band of freebooters, and after sacking and plundering Dunbarton, took refuge in Ireland; but five of his men fell into the king's hands, and were torn in pieces by wild horses. So horrid a punishment, and the exterminating severity exhibited to all connected with the house of Albany, can admit of no justification; and there is every reason to believe, that the early and miserable death of the monarch, is to be traced to the deep feelings of revenge with which some of his nobles from that moment regarded him. Neither is it possible to believe that the king in this instance carried along with him the feelings of the people. Yet looking at the state of things in Scotland, it is easy to understand his object. It was his intention to exhibit to a nobility, long accustomed to regard the laws with contempt, and the royal authority as a name of empty menace, a memorable example of stern and inflexible justice, to convince them that a great change had already taken place in the executive part of the government; to furnish also a warning to the people, of the punishment which awaited those who imagined that fidelity to the commands of their feudal lord was paramount to the ties which bound them to obey the laws of their country.

Having given this severe and sanguinary lesson, the next efforts of the monarch were addressed to the internal administration of his kingdom. From without he had nothing to dread; he was at peace with England, and his marriage with Jane Beaufort, the niece of Cardinal Beaufort, had, from her near relationship to the English monarch, strengthened the ties between the two countries. France was the ancient ally of Scotland; and the Netherlands profited too much from the Scottish trade not to be anxious to preserve the most friendly relations. The king could therefore direct his undivided attention to his affairs at home. His great principle, and it was one worthy of so wise a prince, seems to have been a determination to govern the country through the medium of his parliament. Of these convocations of the national legislature, which had been rarely held under the regencies of the two Albanys, no less than thirteen occurred during his brief reign, which, dating from his return in 1424, lasted only thirteen years. It is to him that Scotland owes the first clear recognition of the principle of representation by the election of the commissaries for shires; it was by him that one of the greatest improvements was introduced into the administration of justice, by the institution of a court of law known by the name of the Session. Nor was this all. Previously to his time, the laws and the acts of parliament had been published in Latin, and the great majority of the inferior judges to whom their execution was entrusted, were unable to understand them.

To remedy this grievance, the king commanded the acts of parliament to be drawn up in the spoken language of the country; an improvement so important, that it forms an era in our legislation. Other points of almost equal interest occupied his attention. By his personal presence in the Highlands, and by the military force which he brought along with him, when he visited those remote districts of his dominions, he introduced laws and order where there had formerly been little else than feudal licence and contempt for all authority. Although he cultivated the arts of peace, he did not forget that its surest preservative was an attention to the military strength of his country. *Weapon-shawings*, or military musters, were held periodically; and having witnessed, when resident in England, and in the war of

Henry the Fifth with France, the great superiority of the English over the Scottish archers, he made it his earnest care that his subjects should cultivate this warlike accomplishment. In many of the acts of the various parliaments of this monarch, we can also trace an attention to the encouragement of agriculture, to the interests of foreign trade and domestic manufactures, to the state of his shipping and navy, to the prices of labour, and the melioration of the condition of the labourers of the soil, which clearly demonstrates the high and important objects that occupied the king's mind, although the means he employed were not exactly those which should have suggested themselves to the experience of a more advanced age. Amid these severer duties, James gave an example to his rude barons of the cultivation of intellectual accomplishments. He was himself a poet; and the king's book, or *KING'S QUAIR*, composed during his captivity in England, is still read by many with delight and enthusiasm. He was a reformer of the language of his country; he composed pieces of music, and sang and accompanied himself on various instruments. It is probable, however, that these employments were rather the solace of his tedious confinement in England, than objects of serious pursuit after his return.

Having so zealously devoted himself to the best interests of his kingdom, James had the satisfaction to see his measures attended with success, and all seemed secure and prosperous, when he suddenly became the victim of a dark conspiracy. Under circumstances of extreme ferocity he was assassinated in the monastery of the Blackfriars at Perth, by Sir Robert Graham, the earl of Athole, and some accomplices who had been dependants of the house of Albany. The court was then at Perth, and James had taken up his residence in the Dominican monastery beside the town. The king was betrayed by his chamberlain, who facilitated the entrance of the conspirators, by removing or damaging the locks of the royal apartments. When the alarm was given, it is said that a lady who waited on the queen, named Catherine Douglas, thrust her arm into the staple of the door, and thus, before it was broken, heroically afforded a brief interval in which the king contrived to conceal himself in a small vaulted chamber, where for some time he evaded discovery. The conspirators, under the idea that he had escaped, had dispersed themselves through the palace, and the unfortunate monarch might have been safe, if he had not prematurely attempted to leave his concealment. The noise which he made recalled one of the ruffians, who shouted to his companions; and springing down into the vault, they threw themselves upon their defenceless victim and murdered him, after a desperate resistance. Although considerable obscurity hangs over the ramifications of the plot which ended thus fatally to the king, there exists no doubt that it owed its origin to indignation at the fate of Albany, and those deep feelings of feudal revenge which had been long cherished by the friends of that unhappy house; affording a terrible lesson to princes of the reaction which may take place, when justice forgets her calmer mood, and pushes her punishments beyond example into revenge.

The death of James the First was a severe calamity to the country, exposing it for the third time since the death of Bruce to all the evils of a long minority. His eldest son, who succeeded to the throne by the title of James the Second, was a boy only six years old; and although the character of the queen-mother was marked by considerable talent and vigour, these qualities were feeble substitutes for the masculine wisdom, the determined courage, and the unwearied care of the husband whom she had lost. Her first duty was the arrest and punishment of his murderers; this she executed with speedy and inimitable severity. But the death of the king once more gave a licence, and offered to the feudal nobles an opportunity of recovering their power of which they were not slow to avail themselves.

Punishment of the murderers.

Scotland.
James II.

Graham, the principal murderer of the late monarch, in the midst of the cruel tortures which preceded his death, had avowed that the day was at hand when the Scottish nobles would venerate his memory for having rid them of a tyrant; and these proud and powerful barons, when they remembered the magnitude of James's plans, and the stern and sometimes unjust severity with which he carried them into execution, could not but feel that now was the time to recover the privileges which they had lost, and to provide some strong and permanent barrier against all future encroachments of the crown.

General observations.

This observation is the key to the history of the country, not only during the reign of this monarch, but for the next century. It unfortunately happened, that with the exception of James the Fourth, who on his accession was a youth of seventeen, Scotland was visited by a series of minorities in James the Second, James the Third, James the Fifth, and Mary, which occupied the long interval between 1436 and 1560; and during this period of more than a century, the extraordinary increase in the power of the nobles, the diminished respect for the crown, and its proportionate weakness against attack and encroachment, are too prominent features to escape notice. We see events, the same in character, and merely varied in name and minor incidents, occurring during the whole time: a monarch of greater or of less energy, emerging from his minority, and making an effort to recover the power which he had lost; a band of turbulent and selfish nobles leagued against him, and only detached from their brethren, and persuaded to act with the crown, by an appeal to their interest and their fears. These remarks were strikingly exemplified in the scenes which took place during the minority of James the Second.

Minority of James II.

Immediately after his coronation, a struggle commenced for the possession of the chief power in the government. In a parliament held at Edinburgh, the queen-mother was entrusted with the custody of the young king, while Archibald earl of Douglas and duke of Touraine, was appointed lieutenant-general of the kingdom, a title probably including all the powers of a military governor. In civil matters the chief authority seems to have fallen into the hands of the chancellor Crichton, who had the command of Edinburgh Castle, in which the queen-mother, with the young prince, had taken refuge soon after the murder of her husband. This princess, however, soon found that Crichton turned the possession of the royal person into an engine for his own advancement, and refused to her that frequent intercourse with her son which she had expected, and to which she was entitled.

Having combined therefore with Sir Alexander Livingston, a baron who had been in favour with the late king, she contrived, by stratagem, to possess herself of the person of the young king, whom she shut up in a large wardrobe chest, and carried as her luggage to Leith, from whence she hastened to Stirling Castle, which had been assigned to her as a jointure-house.

Dreadful state of Scotland.

The kingdom was now divided between three factions, that of the queen and Livingston, who possessed the person of the king, Sir Alexander Crichton the chancellor, and thirdly, the earl of Douglas, whose immense estates in Scotland, and his foreign wealth and influence as duke of Touraine, rendered him by far the most formidable baron in the country. From this moment to the period when James, having attained majority, began to act for himself, an interval of thirteen years, the history of the nation presents little else than one uniform scene of civil anarchy and of unpunished crime. "The young monarch beheld his kingdom converted into a stage on which his nobles contended for the chief power; whilst his subjects were cruelly oppressed, and he himself handed about, a passive puppet, from the failing grasp of one declining faction, into the more iron tute-

lage of a more successful party in the state." In this melancholy drama the chief parts were played by Crichton and Livingston, who, deeming it for their interest to crush the overgrown power of the house of Douglas, inveigled the young earl and his brother into the Castle of Edinburgh, brought suddenly against them a charge of treason, and put them to instant death.

Scotland.
James II.

It was fortunate for the country, that when thus torn by domestic factions, its foreign relations were of a pacific character, England, France, and the Netherlands, being all animated with the most friendly dispositions, while the young king, as he advanced from boyhood into maturer years, developed a character of prudence, vigour, and intelligence, which appeared destined to restore a better state of things to his kingdom. Having married the daughter of the duke of Gueldres, he assumed the government, and selected as his principal councillor, Kennedy, bishop of St. Andrews, a prelate of great wisdom and integrity, whose rank as head of the church, invested him with an authority to which the people, amid the general corruption, looked with much reverence and affection. It was probably by his advice, that James, whose passions were naturally violent, and who viewed with indignation the arrogance of the earl of Douglas, engaged in a systematic plan for the reduction of his overgrown power. Without attempting at once, and by any arbitrary exertion of strength, to deprive this potent chief of his high offices, a measure which might have been followed by extreme commotion, he gradually withdrew from him his countenance and employment; surrounded himself by able and energetic councillors, whom he promoted to the principal places of trust; and thus weakened the authority of the proud baron, rather by the formidable counterpoise which he raised against it, than by any act of open aggression. This conduct was attended with the best results. The earl of Douglas, finding his consequence decreasing, and his power on the wane, retired for a while from Scotland, and respect for the character of the monarch increased with the feeling of security derived from an improved administration of the government. During the absence of the chief, James had time to reduce the minor barons who were his dependants, to attach his own friends more powerfully to his interest, and to concentrate a strength, which, on Douglas's return from Italy, convinced him that he must consent to play a second part to his prince. The result was what might easily have been anticipated. A collision took place between this haughty potentate and the young sovereign whose commands he had so often defied. Douglas, naturally rash and fearless, had consented, under a safeconduct bearing the royal signature, to visit James in the Castle of Stirling. After the royal feast, the king remonstrated with his guest; disclosed to him the proofs he possessed of his combinations against the government; reproached him for the frequent murders of his subjects committed by his order; and condescended to intreat him to forsake such dangerous courses, assuring him of his pardon and favour. Douglas, instead of embracing the offer, replied to it with haughtiness and insolence; and James, losing all command of himself, and braved to his face, drew his dagger and stabbed him to the heart. Falling at his feet, he was instantly despatched by the nobles, who, hearing the commotion, rushed into the apartment.

humbles the house of Douglas.

A.D. 1451.

Murder of the Earl of Douglas by James II.

This atrocious murder was followed by a struggle between the royal party and the friends and vassals of the unfortunate baron, in which the king was completely successful. Sir James Douglas, who succeeded his brother in the earldom, attempted to brave the monarch, renouncing his allegiance, and throwing himself into the arms of England; but his projects against his country were defeated. He was equally unfortunate in his alliance with the Lord of the Isles, whose naval force he directed against the west of Scot-

Scotland. land; and at length, in a fruitless effort to regain his lost power by invading the Merse along with the earl of Northumberland, he was totally routed by the earl of Angus, and driven a landless fugitive into England.

A.D. 1460. The remainder of this reign was employed by the king in an endeavour to complete the work which he had begun; by strengthening the power of the crown, and giving security to the persons and property of his subjects; by attaching to his party the great and influential body of the clergy, carrying into effect various parliamentary enactments for the defence of the borders against the attacks of England, and cultivating the warlike character of his people. Amid these kingly cares, he unwisely suffered himself to be entangled by the contests between the Yorkists and Lancastrians; and having espoused the party of Henry the Sixth, levied an army, and met his death by the bursting of one of his own guns at the siege of Roxburgh. He was succeeded by his son James the Third, a boy in his eighth year.

James III. The death of a sovereign thus cut off in the prime of his manhood and usefulness, leaving an infant successor, would have been a deep calamity at all times, but it was especially so at this moment. James the Second had with uncommon vigour and judgment reduced the overgrown power of his nobles; but he died before his plans were matured, leaving the nation at war with England, the seeds of civil disunion lurking in his kingdom and ready to spring up, and the more northern parts of the realm held by fierce chiefs, who were disposed, on the slightest provocation, to throw off their allegiance.

A.D. 1461. With these island lords, Edward the Fourth entered into a strict alliance; and the banished Douglasses, now become English subjects, agreed to assist him in a confederacy, the object of which was nothing less than the conquest and partition of Scotland. It was to be expected that the favour shewn by that country to the expatriated monarch Henry the Sixth, should have deeply incensed his rival; but the facility with which he purchased his instruments, and found them in the ranks of the Scottish nobles, who became the vassals of England, is a mortifying fact.

From these general remarks it is easy to anticipate the history of this reign, and the scenes which it presented. Into their minuter details it is impossible to enter. For a while the energy of the queen-mother supported the government. On the news of the death of her husband, instead of giving herself up to unavailing grief, she repaired with all speed to the camp before Roxburgh, carrying with her her infant son, now king; him she presented to the nobles, and urged them for him and his father's sake to press forward the siege. She was obeyed, and Roxburgh was taken; but fatal disputes soon succeeded to this success, and it required all the vigour of the queen, with her chief minister, Bishop Kennedy, a man of high character and talent, to struggle against the difficulties which surrounded them. In the northern parts of the kingdom all was unsettled; and the earl of Ross espousing the cause of Edward the Fourth, proclaimed himself king of the Hebrides, while the earl of Angus, on whom, after the fall of the house of Douglas, a large share of their power had devolved, undertook to support the party of Henry the Sixth, contrary to the wishes of the queen and Bishop Kennedy.

At this crisis, the young sovereign lost his mother Mary of Gueldres; and, after a few years, Bishop Kennedy followed her to the grave; events which deprived the government of its best, or rather of its only support. Yet amid all these complicated dangers, it is remarkable, that for fifteen years, the interval occupied by the minority of this prince, the affairs of the country were prosperous.

On the death of Bishop Kennedy, the chief power in the government had fallen into the hands of William Lord Boyd, the high Justiciar, a baron hitherto little known, but whose power rose, in a few years, to a height which almost rivalled that of the once formidable Douglasses. He became

governor of the king's person; filled every office with his dependants; married his eldest son, who was created earl of Arran, to the king's sister; and acquired so much influence over the young king, rather, it would seem, by terror than by love, that he appeared completely subservient to his wishes. The decay of this family was as sudden as its rise. A marriage had been negotiated between the king and Margaret princess of Denmark, and scarcely was it concluded, when a faction of the nobles, at the head of whom was the monarch himself, suddenly attacked the Boyds, arraigned them of high treason, seized and confiscated their large estates, and brought to the scaffold their principal leader. A divorce was instituted against the earl of Arran and his wife, the princess Mary, sister to the king; and she was compelled to give her hand to Lord Hamilton, a favourite of the young monarch. It was through this marriage that the family of Hamilton, which now rose into great power upon the ruin of the Boyds, became, in the subsequent reign of Mary, the nearest heirs to the crown.

James had now attained majority, and in assuming the full administration of the government, he found his kingdom more opulent, more secure, and more powerful, than could have been anticipated from the struggles of his minority. The important isles of Orkney and Zetland had been acquired with the daughter of Denmark; the rich town of Berwick, and the border fortress of Roxburgh, had been occupied by the Scots; the earldom of Ross had been annexed to the crown; the independence and liberty of the Scottish Church established by the erection of St. Andrews into an archbishopric; and, lastly, a marriage treaty with England, by which the youngest daughter of Edward the Fourth was betrothed to the king's eldest son, seemed to promise security and peace in this formidable quarter. If such had already been the success of this reign, it seemed not unreasonable to look forward to still greater prosperity in after years; and yet the history of the country, from the moment when the monarch attained his majority, presents a melancholy contrast to this beginning. This reverse we are inclined to ascribe partly to the personal qualities of the king, partly to some changes in the power and dispositions of the great body of the feudal nobles, which are discernible at this period, not in Scotland only, but in all the feudal kingdoms of Europe.

Some of our historians have represented James the Third as a compound of indolence, caprice, and imbecility; but their opinion seems rash and unfounded. His character was different from that of the age in which he lived, and in some respects it was far beyond it. The times were rude, warlike, and unintellectual. The king was fond of repose, and addicted to a seclusion in which he might devote himself to pursuits which bespoke a refined and cultivated mind: a passion for mathematics, and the study of judicial astrology, a taste for architecture, a love for the science and practice of music, and a generous disposition to patronize the professors of literature and philosophy, rather than to surround himself with a crowd of fierce retainers, were the prominent features in the mind of this unfortunate prince; tastes which have been reprobated by contemporary historians, but which, if duly regulated, were rather praiseworthy than the contrary. Unfortunately, however, this due regulation was wanting. James had the weakness, not only to patronize, but to confer feudal rank, and distinctions, hitherto appropriated to the nobles, upon the professors of his favourite studies. Architects, musicians, painters, and astrologers, were admitted to the familiar converse of the sovereign, while the highest nobles found a cold reception or a positive denial of access. Is it any subject of surprise, that a fierce nobility should have been disgusted with such conduct, and that the king's warlike brothers, the earls of Albany and Mar, should have been regarded as the chief support of the state?

General re-
marks on
the feudal
nobility of
Europe.

But in studying the history of this reign, we shall detect other causes of the sanguinary scenes in which it concluded. Not only were the feudal nobility of Scotland induced by the neglect and favouritism of the king to long for a change, but it is worthy of remark, that for some time previous to this period, the feudal nobility of Europe had been in a state of extraordinary commotion and tumult; and events had occurred which diminished in the eyes of the aristocracy and of the people the respect entertained for the throne. The revolution in England under Henry the Fourth, the subsequent history of that kingdom during the contest between the houses of York and Lancaster, the political struggles in France under Louis the Eleventh, the relative condition of the greater nobles in Germany and of the rights of the imperial crown under the emperor Sigismund, the dissensions which divided the Netherlands, and the civil factions which agitated the government in Spain, all combined to render resistance so common, and so lucrative in the eyes of the feudal nobility in Europe, that its frequency can be a subject of little wonder; and if, when we take into account the frequent communication between Scotland and the continent during the period of these commotions, we may easily imagine their effect upon the still ruder and more independent nobility of that country. We have been tempted to throw out these general observations, because the reign of James the Third is in one respect most remarkable. It is the era from which we may date the rise of a republican spirit, and the first propagation of those popular principles, of which the operation can be traced, in a greater or less degree, through the whole course of its subsequent history.

Contest of
James III.
with his
brothers,
Albany and
Mar.
A.D. 1479
—1480.

To return from such remarks to the events of this reign, we find the king engaged in a contest with his two powerful brothers, Albany and Mar. To the first had been entrusted the wardenship of the east marches, the government of Berwick, and the castle of Dunbar, the principal key of the kingdom; and there seems no doubt that he had abused his high powers to an extent which bordered upon treason. Against Mar was brought a still more atrocious charge. He had plotted, it was said, to cause the king's death by magical arts; and being convicted by the evidence of his wizard accomplices, was imprisoned, and, according to one account, secretly executed. Another story ascribes his death to the consequences of a fever, for which having a vein opened, he in an excess of phrensy tore off his bandages and bled to death. Against Albany the king proceeded with unusual vigour. He attacked him in Dunbar, made himself master of the fortress, and would have seized his person, but the rebellious prince availed himself of the situation of the castle, which was open to the sea, and fled first to England, and afterwards to France.

War with
England.
A.D. 1480.

At this moment, Louis the Eleventh was at war with Edward the Fourth, and he unfortunately possessed such influence over the Scottish king, that he brought about a rupture between James and Edward. It was a step signally impolitic. Albany, the king's brother, returning from France, threw himself into the arms of England; the nobility were full of complaints against the government; the Lord of the Isles embraced the interests of Edward; and after a long interval of peace had softened the national animosity between the kingdoms, it was a miserable sight once more to witness the renewal of hostilities.

This contest led to some extraordinary scenes. Albany having openly avowed his purpose to dethrone his brother, assumed the title of Alexander king of Scotland, and entered into a treaty with Edward, by which he basely consented to sacrifice the independence and dismember some of the finest portions of the kingdom. To effect his designs, he had the address not only to secure the co-operation of the banished earl of Douglas, with the Lord of the Isles and his northern vassals, but he detached from James's service Angus,

Gray, Huntly, Lennox, and many others of the leading nobility in Scotland. A conspiracy was formed against the monarch and his favourites; the conjuncture of his assembling his army, preparatory to his invasion of England, was deemed the most favourable moment for the execution of their purpose; and in the camp at Lauder its success was equally sudden and terrible. The nobles, led by Angus, seized Cochrane, James's favourite, who, from a mean station, had been promoted to high rank and enriched with the earldom of Mar; they then broke into the king's tent, made him prisoner, arrested the band of ignoble associates who shared his confidence, and proceeded to inflict summary vengeance on them all. Cochrane was hanged over the bridge of Lauder; Rogers, a musician, Hommel, Leonard, Preston and others, shared his fate; and the unfortunate monarch, having been conveyed to the capital, was shut up in the castle of Edinburgh. The result of this success was what might have been expected. Albany, who all along had acted from motives of personal ambition, having once possessed himself of the king's person, ruled the government at his will.

Scotland.
James III.
A.D. 1482.
Conspiracy
against the
king.

But usurpation of the supreme power was not the full extent of his treachery. He attached Edward the Fourth to his service by the sacrifice of the national independence. In a secret treaty, the English prince engaged to assist Albany, who hitherto had only assumed the title of lieutenant-general of the kingdom, in placing the crown on his own head; and as the base price of this assistance, the new king and his nobles agreed to withdraw their oaths from king James, and to live under the sole allegiance of the king of England. It may give us some idea of the low estate to which the nobles of Scotland had fallen, when we mention, that not only the earl of Douglas, now banished and living in England, but the earls of Angus, Buchan, Athole, and many others, were willing parties to this wanton sacrifice of their country.

A.D. 1482.

The plot, however, was defeated, and happily a party yet remained among the nobles, who, though their vengeance against the king's favourites, were friends to the crown and to the country. They had joined Albany with the object of sacrificing Cochrane and his associates, but had been kept in ignorance of his ultimate intentions; and the moment these became apparent, they united with the king and overwhelmed the opposite faction. And here, in the manner in which Albany was treated, is to be found the cause of all the subsequent misfortunes of the king. His brother deserved punishment, and ought to have met with no pity. He had been guilty of open and repeated treasons, had levied war against his prince; and imprisoned his royal person, leagued himself with his enemies, sold the independence of his country, and assumed the title of king. His guilt and ambition had seduced from their allegiance a large party of the nobles; and if ever there was a time in which a great example was to be made, that time was now come. Yet, instead of this wholesome severity, the duke of Albany was treated with a lenity for which it is impossible to account. On acknowledging his manifold treasons, and laying down his office of lieutenant-general, he not only received a full pardon, but was permitted to retain not only his vast estates, but his wardenship of the marches, and was simply interdicted from coming within six miles of the court, or continuing his illegal combination with Angus, Athole, and Buchan.

Impolitic
lenity to
Albany.
A.D. 1482.

Whether we are to ascribe this misplaced mercy to the king's attachment to his brother, or to a suspicion that he was not strong enough to inflict a more exemplary punishment, it is difficult to decide; but the result demonstrated what has been so often taught, the folly of a misplaced lenity. In a few weeks Albany was again in rebellion. At his invitation, an English army invaded Scotland; Dunbar, the most important castle in the kingdom, as the key of the eastern

Renewed
rebellion of
Albany.

Scotland. borders, was delivered up by this base person to the enemy, while he himself fled into England, and organized with James III. Edward the Fourth the plan of a more formidable invasion. At this crisis occurred the death of the English monarch, and the seizure of the crown by Richard the Third; events which gave James an interval of rest, in which he acted with unusual firmness and energy. He assembled a parliament at Edinburgh, in which the sentence of forfeiture was pronounced against the duke of Albany and all his adherents; he entered into an intimate alliance with Charles the Eighth of France, and he concluded a truce with Richard the Third, who was too much occupied with his own complicated affairs, to have leisure or inclination to continue the war with Scotland. Thus strengthened, the king found it no difficult matter to resist the last effort of Albany and Douglas, who having once more invaded Scotland at the head of a small force, were completely defeated at Lochmaben; an event followed not long after by the death of Douglas, in the abbey of Lindores, where he had been confined, and of Albany, who was slain in a tournament in France.

Final defeat of Albany. A.D. 1483.

The Scottish nobles renewed their intrigues against James. It might have been expected that James, who was thus delivered from his most powerful enemies, would have been permitted to reign in peace. But he was destined to be unfortunate; and, although his nobles had refused to alter the succession in favour of his ambitious brother, they soon after appear to have entered into intrigues with England for the purpose of placing the crown on the head of his son, the prince of Scotland, who was then a youth in his sixteenth year. Much obscurity hangs over the origin of this conspiracy. Advances seem first to have been made by the faction of the prince to Richard the Third, who, although he was animated by an anxious desire to remain at peace with Scotland, did not scruple to hold out secret encouragement to James's enemies. To what extent such secret negotiations proceeded, it is not easy to discover; but after the death of Richard they were renewed, and his successor, Henry the Seventh, showed as little scruple as his predecessor in encouraging the malcontents.

Causes of the conspiracy against the king.

Five years had now elapsed since the death of Cochrane the king's favourite, and the dreadful scenes exhibited in the camp at Lauder. Since that time a change appears to have taken place in James's character. His devotion to study and retirement had given way to a sense of duty; he had exhibited not only capacity for government, but unwonted resolution in the attack and discomfiture of his enemies; and, although the impolitic lenity with which he had treated Albany was rather a weakness than a virtue, it was believed that he was now convinced of his error, and had resolved that the laws against treason should no longer slumber or be despised. These reflections filled the barons who had been conspirators at Lauder with the greatest alarm. They were well aware that a sentence of treason hung over their heads. They knew themselves guilty of aggravated offences; they had imprisoned the king, usurped the government, and without regular trial or conviction, had put his favourites and councillors to death. As long as the chief power had remained in their own hands, they felt tolerably secure, but circumstances had once more restored the king to his wonted authority; and the dread of the retaliation which might be inflicted, with the certainty that, at all events, their power would be abridged, appears once more to have driven them into rebellion. Such at least seems to be the most probable way of accounting for the rise of that conspiracy in which this unfortunate prince lost his crown and his life. The worst feature in the story is the unworthy part acted in it by his son, afterwards James the Fourth, over whom the malcontent barons gained a fatal influence, and who, seduced by the prospect of a crown, lent himself a tool to the dethronement of his father. When once organized, the

plot proceeded to its maturity, and thence hurried on to Scotland. its catastrophe with an appalling rapidity.

The two parties of the king and the conspirators first tried their mutual strength in a Parliament. It was proposed by the popular faction that an amicable adjustment of all disputes should take place between themselves and the sovereign, and that such barons as were still obnoxious to a charge of treason, should receive a full pardon. To this the party of the king peremptorily refused their consent. James, aware of the unworthy conduct of his son, the heir apparent, created his second son duke of Ormond, and seemed to point him out as his successor. He at the same time rewarded the principal barons who had espoused his interest, and took decisive measures, by the appointment of vigorous officers, to have the laws against treason severely administered. These steps convinced his opponents that their proceedings had been discovered; and without giving the monarch time to assemble an army, or even take measures for his personal defence, they threw off the mask, broke out into open rebellion, declared that James the Third, by his crimes and oppressions, had forfeited all title to the throne, and proclaimed his son, by the title of James the Fourth.

Even now, had not the king suffered himself to be misled by his paternal feelings, the conflict might have concluded in his favour; for it is evident that a large class of the nobility, and the whole body of the people, were against these nefarious proceedings. So strong was this feeling, that James, who, on the advance of the rebels to the capital, had taken refuge in the northern part of his kingdom, soon found himself at the head of a formidable army, and advanced instantly against the insurgents, whom he found stationed at Blackness, near Linlithgow.

It was now the time for action, the time for a determined execution of those laws which late years had seen so constantly treated with contempt. But whether the affectionate heart of the monarch sickened at the sight of his subjects in mortal array against each other, or some symptoms of disaffection breaking out in his own force rendered him apprehensive of their fidelity, James not only consented to an accommodation, but offered terms to the prince and his associates, which were culpably lenient. He permitted the son who had usurped his kingly name and prerogative, and the subjects who had defied the authority of the crown and the laws, to negotiate with arms in their hands on a footing of equality. On the part of the misguided prince, now no longer a boy, no petition for forgiveness, no expression of penitence was suffered to escape. In the pacification at Blackness, the youth spoke throughout, not as a son conscious that he had offended, but as a sovereign transacting a treaty with his equal. The treaty, in truth, was a triumph to the discontented nobles. The prince and his friends who had encouraged him to resistance, agreed to become obedient subjects on receiving the king's forgiveness, while the monarch not only consented that their lives, honours, and estates, should be preserved, but that the household of the heir apparent should be maintained, and his friends and adherents supported with due dignity. It required little penetration to foresee that the tranquillity which was established on such a foundation could not long subsist. It was a confession of weakness pronounced at a time when firmness at least, if not severity, was the only guide to the permanent settlement of the convulsions which agitated the kingdom.

The consequences which any person of ordinary judgment might have anticipated, were not long of occurring. James retired to his capital, his army was dismissed, the northern barons, whose valour had saved his crown, were permitted to return to their estates, and James, anticipating a continuance of tranquillity, proceeded to reward his friends and re-organize his court, when he received intelligence that his son the prince, with the same fierce barons

Treaty of Blackness.

Renewed rebellion of the prince and his party.

Scotland. who had so lately sworn allegiance, were again in arms, and in more formidable numbers than before. In this emergency, indeed, the king acted with courage and promptitude; but having disbanded the strongest division of his army, which consisted of his northern barons and their vassals, the force which he mustered was much inferior to that of his opponents. It was therefore determined to await in the capital the arrival of the northern barons; but unfortunately this resolution was abandoned, and the monarch with inferior numbers, attacked the insurgents, who were commanded by the prince his son, at Sauchy Burn, within a mile of Bannockburn. The consequences proved most calamitous. The royal forces, after an obstinate struggle, gave way to their opponents; and James, flying from the field, was murdered by an unknown hand, at a little hamlet called Miltown, a few miles distant from the field of battle. He perished in the prime of life, and it is said his youthful successor was seized with overwhelming remorse on being informed of the miserable fate of his father. However this may be, he was immediately proclaimed king, and the homage of his barons, the early possession of a sceptre, and the lustre of a court, soon stifled his repentant feelings.

Defeat and death of James III. at Sauchy. A.D. 1488.

James IV. proclaimed king.

Character of James III.

General observations.

The character of James the Third has been represented by Boyce, Buchanan, and those writers who have been contented to follow their authority, as a compound of weakness, wilfulness, and crime; a character contradicted by the history of his reign. It must indeed be admitted, that James's indulgent treatment of his rebellious subjects, and of the prince his son, partook of weakness, although there are few father's hearts in which he will not find an advocate; but in other respects the best refutation of the ideal pictures of Buchanan is to be found in the real history of the reign. James's misfortunes are, in truth, to be attributed more to the extraordinary circumstances of the times in which he lived, than to any flagrant vices or defects in the monarch himself. At this period, in almost every kingdom in Europe with which Scotland was connected, the power of the great feudal nobles, and that of the sovereign, had been arrayed in jealous hostility against each other. The time appeared to have arrived when both parties seemed convinced that they were on the confines of a great change; that the power of the throne must either sink under the superior strength of the greater nobles, or the independence and tyranny of these feudal tyrants receive a blow from which it would not be easy for them to recover. In the different countries of Europe indeed, the result was not uniform, but in all the same elements of faction were seen arrayed against each other. Thus, in France, the struggle under Louis the Eleventh had terminated in favour of the crown; yet the lesson to be derived from it was not lost upon the Scottish nobility, who were in constant communication with this country. In Flanders and the states of Holland, they had before them the spectacle of an independent prince deposed and imprisoned by his son; and in Germany the reign of Frederic the Third, who was contemporary with James the Third of Scotland, presented one constant scene of struggle between the emperor and his nobility, in which this capricious potentate was uniformly defeated.

There is yet one other observation to be made upon this remarkable revolution, by which, for the first time in Scottish history, a king was solemnly deposed by a faction of his own subjects. Although the barons who led the successful faction represented themselves as the friends of liberty, driven to a resistance of royal oppression, the middle classes and the body of the people took no share in the struggle. Many individuals belonging to these classes, who were feudal vassals of the great lords, must no doubt have been compelled to serve under them; but as far as they were represented by the commissaries of burghs who sat in Parliament, they appear in this struggle to have joined the

party of the sovereign and the clergy, by whom, during this reign, frequent efforts were made to introduce a more effectual administration of justice, and a greater respect for property and the rights of individuals.

Scotland. James IV. A.D. 1488.

Laws, mingled with alternate threats and exhortations, are to be found upon these subjects in the records of each successive Parliament of this reign; but the offenders continued refractory, and these offenders were the very men, whose offices, if conscientiously administered, ought to have secured the rights of the great body of the people. It was the nobles who were the justiciars, chancellors, chamberlains, sheriffs; and these, it was well known, were often the worst oppressors, partial and venal in their administration of justice, severe in exacting obedience, and opposed to every right which interfered with their own power. Their privileges as feudal nobles came repeatedly into direct collision with their duties as servants of the government, and they made no scruple to sacrifice the last to the preservation of the first; duty to privilege and self-interest. It is from this cause that we discern an honourable distinction between the clergy and the feudal nobles, in the struggle between the crown and the faction by which it was attacked. In this contest, wherever the greater offices in the government were in the hands of the clergy, it will be found that they generally supported the sovereign; when they were entrusted to the nobility they almost uniformly combined against him.

When James the Fourth succeeded to the throne left James IV. vacant by the murder of his father, he was in his seventeenth year; but his character at that early age had vigorously developed itself, and although it has sometimes been asserted, there is no reason to believe that the prince had been an unwilling assistant, or a passive tool in the hands of the conspirators. Their first care was to hold at Scone the ceremony of the coronation; their next to conclude a three years' truce with England, then under the government of Henry the Seventh; their third, to assemble a Parliament and provide for their own safety, by the forfeiture of their enemies and the rewards distributed to their friends.

And here it is not unimportant to mark the course which they artfully pursued. If any party in the state were at this time liable to a charge of treason, it was evidently the friends of the young king, and not the barons who had continued faithful to his father; but the difference consisted in this, that the treason of the prince's party had been accompanied with success, whereas the resistance of the friends of his father had been overwhelmed, and himself dethroned and murdered. They who now were in possession of the supreme power, therefore boldly turned the tables, summoned their opponents on a charge of treason, and as the facts were notorious, pronounced sentence against them. They next voted their own acquittal in strong and significant terms; and considering under whose dictation the act was drawn up, it is difficult to read, without a smile, the compliments pronounced upon their treason, when they declare that their sovereign lord, and his *true* barons, who served with him in the field, were innocent of the late battle and pursuit, and had no blame in exciting the disturbances which had terminated so fatally.

The innocence of these barons was however far from being generally admitted; and the Parliament had scarcely risen, when Lennox, Huntly, Marischal, and other powerful chiefs, rose in arms to avenge the death of their king. Lord Forbes, who had joined them, marched through the country, bearing the bloody shirt of the unfortunate prince suspended from a spear; and had it not been for the promptitude with which their opponents met the enterprise, the movements of Lennox, who advanced upon Stirling, might have delivered the country from their domination. But this chief, betrayed by some of his followers, was surprised and completely routed by Lord Drummond at Fal-

Tranquillity being restored, James, as he approached manhood, exhibited signs of considerable ability, and energy in following up his purposes. Amid a love of pleasure, which had never been restrained by early discipline, and often hurried him into foolish and criminal excesses, he did not so far forget himself as to neglect his higher duties. He cultivated amicable relations with England, renewed the league with France, entered into a commercial alliance with Denmark, and in a Parliament held in the capital, directed his earnest endeavours to the establishment of good order, and the administration of equal justice throughout the kingdom. Happily the character of Henry the Seventh, his caution, sagacity, command of temper, and earnest desire for peace, were well calculated to check the ardour and impetuosity of the Scottish prince; and for twenty years, with the exception of a brief effort made by James in favour of Perkin Warbeck, the country enjoyed the blessing of repose.

This interval was wisely occupied by the monarch in reducing the northern portion of his dominions to obedience, and in an attempt, by the frequent convocation of his parliament, to promulgate useful laws, and, which proved a more difficult task, enforce their observance. It was evident, that as the king grew older, he became convinced of the fatal errors of his early years, and upbraided himself for having lent himself to a selfish and unprincipled faction, who, unless he consulted their wishes and gratified their ambition, might be disposed to treat him as they had treated his father. Aware that they were too powerful to be quelled, he prudently adopted a safer course, by gradually recalling to confidence and power the friends and ministers of his father. Among these, one of the ablest was Andrew Wood of Largo. This remarkable man, whose genius for naval adventure was combined with a powerful intellect in civil affairs, rose by degrees to be one of James's most confidential servants, and appears to have been almost exclusively trusted in his financial concerns. We find in him many qualities apparently inconsistent, when judged by modern notions. He was originally nothing more than an enterprising merchant; but at this time all merchant ships were armed, and generally acted on an emergency as ships of war. Wood, therefore, in the course of a life devoted to mercantile and commercial adventure, had become a skilful naval commander; and in the commencement of this reign, when the English privateers infested the narrow seas and attacked the Scottish shipping, had signalled himself by the capture of five vessels, and the subsequent defeat of a second squadron, commanded by Stephen Bull a London merchant. These successes endeared him to the king, who had a passion for naval enterprise, and lost no opportunity of encouraging such a taste in his nobles. The advice of such a councillor as Wood, was of essential service to James. His travels in different countries had enlarged his mind, and made him ready to adopt their improvements in various points in which Scotland was behind her neighbours. He had been an affectionate servant of the late king; and to his advice we are perhaps to trace the coldness and severity with which James now began to treat some of the leaders in the late rebellion. Yet, while the monarch endeavoured to keep their power in check, he showed his prudence in abstaining from such severe measures as might have driven them into open opposition; and combining firmness with gentleness, he contrived to reconcile the opposite factions among his nobles, and to maintain his own authority over them all.

In the midst of these cares, the state of the Highlands

occupied his special attention, and the principles of his policy were certainly wise and salutary. He endeavoured by every means in his power to attach to his interests the principal chiefs of these remote districts; he contrived, through them, to overawe and subdue the petty island princes who affected independence; he carried into their territories, which had been hitherto too exclusively governed by their own capricious and often tyrannical institutions, a more regular and rapid administration of civil and criminal justice, making them obedient to the same laws which regulated his lowland dominions; and lastly, he repeatedly visited the Highlands in person. In 1490, on two different occasions, the king rode from Perth across the "Mount," a term applied to the chain of mountains which extends from the Mearns to the head of Loch Rannoch, accompanied by his chief lords and councillors. In 1493, he twice penetrated into the Highlands, and in the succeeding year thrice visited the isles.

One of these voyages, undertaken in 1494, during the spring months, was conducted with great state. He was accompanied by his chief ministers, his household, and a considerable fleet, many of the vessels composing which were fitted out by the nobles at their own expense. The pomp of the armament was well calculated to impress upon such wild districts an idea of the wealth and military power of the prince; while the rapidity of his progress, the success with which he punished all who braved his power, his generosity to those who sued for mercy, his familiarity with the lower classes of his subjects, and his own gay manners, increased his popularity, and confirmed the ties of allegiance. On arriving in this voyage at Tarbert in Kentire, James repaired the fort originally built there by Bruce, established an emporium for his shipping, transported thither his artillery, and by such wise and energetic precautions, ensured peace to districts which formerly had derided the royal vengeance. The chiefs, aware that the king could carry hostilities at a short warning into the heart of their territories, submitted to a force which it would have been vain to resist. One only, the Lord of the Isles, had the folly to defy the royal vengeance, and soon repented of the Lord his temerity. He was summoned to take his trial for treason, pronounced guilty, stripped of his almost regal power, and his lands and possessions forfeited to the crown.

We must now advert for a moment to a singular episode in the history of the country. Perkin Warbeck, whose mysterious story still offers some field for historical scepticism, after his first unsuccessful attempt upon the English crown, took refuge in Scotland in the year 1495. There seems strong ground for suspecting that James, at the request of the duchess of Burgundy, had embraced the interests of this adventurer at a much earlier period than is generally suspected; but whether he really believed him to be the prince whose name he assumed, or whether he was induced to espouse his cause as a means of weakening England, is not easily discoverable. It is certain, however, that in 1494, the Scottish king had projected an invasion of England in favour of the duke of York, and that the plan miscarried by the treachery of Perkin's friends.

On the arrival of the mysterious stranger at his court, James at once received him with royal honours, gave him in marriage a lady connected with the royal family,¹ collected an army, and, attended by Warbeck, invaded Northumberland. But the proceeding was rash and impolitic; and its author found, within a short time, that the cause of Perkin was unpopular in England, and the war unacceptable to his own subjects. So deep was the national antipathy between the two nations, that the English no sooner saw the claimant of the crown invading their country at the head of a Scottish force, than they suddenly cooled in

¹ Catherine Gordon, the daughter of the Earl of Huntly.

Scotland. their enthusiasm; and the desolating fury with which James IV. conducted hostilities, supported by a body of foreign mercenaries, completed their disgust. It was evident to the king that Henry the Seventh held his crown by a tenure too firm to be shaken by so feeble a hand as Perkin's; and having drawn back his army, he soon after concluded a truce with England, and refusing to deliver him to Henry, took measures for his quiet and amicable retreat from his dominions.

James's These negotiations having been concluded, James had wise conduct to his nobility. leisure to attend to his affairs at home. He was aware that the chief errors of his father's reign were to be traced to his neglect of the great body of his nobility. To reign without their cordial co-operation was impossible, as long as Scotland remained a feudal kingdom; and it was happy for this prince that the course of conduct which his own disposition prompted him to pursue, was the best calculated to render him a favourite with this influential body. Under the reign of his father the nobles had little intercourse with their prince. They lived in gloomy independence at a distance from court, resorted thither only on occasions of state or counsel; and when parliament was ended, or the emergency had passed away, they returned to their castles full of complaints against a system which made them strangers to their sovereign and ciphers in the government.

Increase of the power of the Crown. All this was happily changed under the present monarch. Affable in his manners, a lover of magnificence, and a still greater lover of mirth and pleasure, the prince delighted to see himself encircled by a splendid nobility. He bestowed upon his highest barons those offices in his household which ensured their attendance upon his person; his court became a scene of perpetual amusement, in which his nobles laboured to surpass each other in extravagance and revelry; and while they impoverished themselves, they became more dependent upon the sovereign. In this manner the seclusion of their own castles became irksome to them; as their residence on their estates was less frequent, the ties which bound their vassals to their service were loosened; and the consequences proved in every way favourable to the royal authority.

State of the navy. James now turned his principal attention to his navy. It is well known that at this moment the maritime enterprises of the Portuguese, and the discoveries of Columbus, had created a wonderful sensation throughout Europe. Even the cautious and calculating spirit of Henry the Seventh had caught fire at the triumphs of naval enterprise; and an expedition which sailed from England under the command of John Cabot, a Venetian merchant, and his son Sebastian, was rewarded by the discovery of North America. These successes roused the adventurous spirit of the Scottish king, and as Scotland had hitherto been deficient in any thing approaching to a navy, he became eager to supply the want, and maintain his place with other continental kingdoms. With this view, he paid great attention to his fisheries, and to foreign commerce, the best nurseries of seamen; and those enterprising merchants and hardy mariners who had hitherto speculated solely on their own capital, found themselves encouraged by the king and the government.

The king encourages his fisheries, his navy, and his commerce. In a former parliament, complaints had been made of the want of boats to be employed in the fisheries, and of the wealth lost to the country from the few ships to be found in its sea-ports. It was now provided, that vessels of twenty tons and upwards, should be built in all the principal sea-ports, and that all stout vagrants found in these districts should be impressed, and compelled to learn the trade of mariners. Among his merchants and private traders were many men of ability, whom the king treated with favour. He exhorted them to extend their voyages, to arm their trading ships, to import artillery, and to build ships of force at home. Nor was this all. He studied the subject of his navy, and made himself personally familiar with its details;

he practised gunnery, embarked in little experimental voyages, conversed with his mariners, and visited familiarly at the houses of his merchants and sea officers, by whom his fame was carried to foreign countries. All this was useful. The best foreign artificers being sure of a generous reception, flocked to Scotland from France, Italy, and the Low Countries; and if the king's credulity sometimes encouraged impostors, his enthusiasm also collected round him men of real knowledge and experience.

While we advert to these laudable exertions of the king, University the labours of an enlightened prelate for the dissemination of useful learning, ought not to be passed over. Scotland, at this period, possessed only two universities, St. Andrews, founded in the beginning of the fifteenth century, and Glasgow, founded in 1453. To these Elphinstone, bishop of Aberdeen, now added a third. The papal bull was issued in 1494, but the buildings of King's College were not completed till about the year 1500. It supported professors of divinity, of the civil and canon law, of medicine, and of classical literature, in which its first principal, Hector Boece or Boyce, was no contemptible proficient. Soon after this, James married the princess Margaret of England, daughter of Henry the Seventh; a wise and politic alliance, although in the marriage treaty the diplomatic skill and penurious habits of her father seemed to have gained a victory over the Scottish commissioners.

From the public rejoicings that followed his nuptials, Northern the king was called to repress a rebellion in the north, which appears to have been excited by an imprudent alteration in the policy hitherto pursued in these quarters. This led to a confederation of the Highland chiefs, who determined to reinstate in his insular sovereignty the grandson of the last lord of the Isles; and so deep was the discontent, that it required the utmost efforts of the prince to restore these remote districts to tranquillity. In this he at last succeeded, divided them into new sheriffdoms, repaired and garrisoned the castles in the hands of the crown, and sent Wood and Barton, two of his best officers, with a small squadron to co-operate with Arran, his lieutenant-general, in reducing the insurgent chiefs. Having adopted these measures, which were soon followed by the complete re-establishment of tranquillity, James, at the head of a considerable force, visited the border districts, and, assisted by Lord Dacre, the English warden, compelled the Armstrongs, Jardines, and other powerful septs, to forsake their habits of plunder, and respect the laws. He then proceeded by negotiations to strengthen his pacific relations with France, and the Netherlands; while he prudently resisted the solicitations of Pope Julius the Second, who endeavoured to detach him from his alliance with Louis, and to induce him to join the emperor and the Venetians in their attempt to check the successes of the French in Italy.

Not long after this, occurred the death of Henry the Seventh, an event unfavourable to Scotland. The proud, capricious, and tyrannical character of his son and successor Henry the Eighth, rendered him little qualified to respect or preserve the pacific relations with that country, which had been wisely cultivated by his father; and it soon appeared that the Scottish prince, a spirited monarch, jealous of his own dignity, and little accustomed to dictation, was not disposed to submit to it from his brother-in-law.

Matters proceeded smoothly for some time; but when Henry the Eighth engaged in war with France, the ancient ally of Scotland, James at once warmly espoused the party of Louis, and although against the best interests of his kingdom, suffered himself to be drawn into the quarrel. The history of the war is well known. Julius the Second having, in conjunction with Ferdinand of Spain, gained all he wished, by the league of Cambray, became alarmed at the progress of the French in Italy, and to check their arms, prevailed upon Henry the Eighth, whose imagination had

succeeds to the English throne.

Quarrel between James IV. and Henry.

Scotland. lately been dazzled by dreams of Edward the Third and Henry the Fifth, to invade France. Louis, on the other hand, negotiated with James the Fourth, and to embarrass the king of England, induced him to declare war against Henry the Eighth. It was a fatal resolution; but the Scottish prince was beloved by his people, and so popular with the great body of his nobles, that his appeal to arms was answered by the muster of one of the most numerous and best equipped armies, and one of the most formidable fleets ever fitted out by the country.

The Scottish fleet dispersed.

The fleet amounted to twenty-three sail, of which thirteen were large ships, the rest small armed craft. Of this armament the destination was Ireland, but its command was entrusted to the earl of Arran, an officer of no experience in naval affairs; and the result was its total dispersion and discomfiture. The land army, on the other hand, which was led by the king in person, amounted to a force little short of a hundred thousand strong, with which James invaded England, and after some slight successes, encamped in a strong position on the hill or rising ground of Floddon, one of the last and lowest eminences which detach themselves from the range of the Cheviots. It was a strong position, impregnable on each flank, and in front defended by the Till, a deep and sluggish stream, which is tributary to the Tweed.

Defeat of the Scottish army at Floddon, 9th Sept. A.D. 1513.

Henry the Eighth, before passing with his army into France, had entrusted the defence of his kingdom to the earl of Surrey, a brave and experienced officer, who lost no time in collecting a force with which, although it did not amount to half the number of the Scots, he did not hesitate to march against the king. But what he wanted in numbers, Surrey supplied by military experience and coolness; while James, blind, obstinate, and attending only to the dictates of his personal courage, threw away his advantages both of numbers and position. The result was one of the most calamitous defeats ever experienced before or since by Scotland. Surrey was permitted by the king to cross the Till in the face of his army. Contrary to the remonstrances of his veteran officers, he would suffer no one to attack him; although the moment was so favourable that, if Angus, Lindsay, and Huntly had been allowed to charge with their men, nothing less than a miracle could have saved the English earl. To the entreaties of Borthwick, the master of his artillery, he was equally obstinate. Had the guns been brought to bear upon the enemy when crossing the bridge of the Till, they must either have been beaten back or thrown into such disorder as would have exposed them to immediate rout; but this too the king would not suffer. With amazing folly he renounced the use of his artillery, that arm of war which, with so great care and expense, he had strengthened or rather created, at the very moment it became serviceable, and might have saved himself and his army. What James's motive was in this, unless the indulgence of some idle chivalrous punctilio, it is impossible to discover; but its consequences were grievous. Surrey completed his arrangements, passed the ford and the bridge, marshalled his army at leisure, and placing his entire line between James and his country, advanced by an easy ascent upon the rear of the Scottish army. Upon this the king set fire to the huts and temporary booths of his encampment, and descended the hill with the object of pre-occupying an eminence on which the village of Branksome is built. His army was divided into five battles, some of which had assumed the form of squares, some of wedges, all being drawn up in a line about a bow-shot distance from each other. The enemy were divided into two battles, each of which had two wings. The English van was led by lord Thomas and lord Edmund Howard, Surrey himself commanded the centre of the host, Sir Edward Stanley and lord Dacre the rear and the reserve. On the side of the Scots, Huntly and Hume led the advance, the king the

centre, and the earls of Lennox and Argyll the rear. The Scotland. battle commenced at four in the afternoon, and after an obstinate contest, which continued till nightfall, concluded in the total defeat of the Scots. Among the slain was the king himself, who, surrounded by a circle of his nobles, had fought with desperate courage, besides thirteen earls, and fifteen lords and chiefs of clans. The loss of common soldiers was estimated at ten thousand men. Of the gentry it is impossible to say how many were slain. Scarcely a family of note could say that they had not lost one or more relatives, while some had to lament the death of all their sons. Whether we regard this miserable slaughter of the sovereign with the flower of his nobility and country, or look to the long and sickening train of national calamities which it entailed upon the kingdom, it is not too much to pronounce the battle of Floddon the greatest national misfortune ever endured by Scotland.

The character of the unfortunate monarch who thus perished in the prime of life, for James had not completed his forty-second year, was marked by very contradictory qualities. Although devoted to his pleasures, wilful, and impetuous, he was energetic and indefatigable in the administration of justice, a patron of all the useful arts, and laudably zealous for the introduction of law and order into the remotest parts of his dominions. The commerce and the agriculture of the country, the means of increasing the national security, the navy, the fisheries, the manufactures, were all subjects of interest to him; and his genuine kindness of heart, and accessibility to the lowest classes of his subjects, rendered him deservedly beloved. Yet he plunged needlessly into all the miseries of war, and his thirst for individual honour, and an obstinate adherence to his own judgment, led to the sacrifice of his army and his life, and once more exposed the kingdom to the complicated evils of a minority.

The news of defeat always flies rapidly, and the full extent of the national calamity soon became known in the capital, which was seized with the utmost sorrow and terror. The magistrates, with the forces of the borough, had joined the king's army, and many of them shared his fate; but the merchants, to whom their powers had been deputed, acted with much firmness and spirit. They armed the townsmen, published a proclamation, enjoining the women who were seen waiting in the streets to cease their lamentations, and repair to the churches, where they might pray for their lords and husbands, and took all the necessary precautions to defend the city in the event of any immediate attack. Soon afterwards the welcome intelligence arrived that Surrey, having suffered severely in the battle, had disbanded his host, and a breathing interval was allowed. The infant king was crowned at Scone, the castle of Stirling appointed as his residence, the government of it entrusted to lord Borthwick, and the archbishop of Glasgow, with the earls of Huntly and Angus, selected to be the councillors of the queen-mother, till a parliament should assemble. At the same time suspicions seem to have arisen that too much influence in the government ought not to be given to this princess, whose near connection with England might subject her to foreign influence; and a secret message was dispatched to France inviting the duke of Albany, the next heir to the throne, to repair to Scotland and assume the office of regent.

It was necessary, in the mean time, to consider the best State of schemes for the restoration of tranquillity and the preservation of order under the shock which a defeat so terrible had given to the country; and the prospect which presented itself, on taking a general view of the condition of the kingdom, was discouraging. The dignified clergy, a class of men who were undoubtedly the ablest and the best educated in Scotland, from whose ranks the state had been accustomed to look for its wisest councillors, were divid-

Scotland. ed into factions among themselves occasioned by the vacant benefices. The archbishop of St. Andrews, the prelates of Caithness and the Isles, and other ecclesiastical dignitaries, had fallen in the field of Floddon; and the intrigues of the various claimants for these high prizes distracted the church and the council. There were evils also to be dreaded from the character and youth of the queen-mother. Margaret had been married at fourteen, and was now only twenty-four. Her talents were excellent, as we know from the testimony of such able judges as Surrey, Dacre, and Wolsey; but in some points she too nearly resembled her brother Henry the Eighth. She was hasty in her resentment, headstrong, and often ready to sacrifice her calmer judgment to her passion or her pleasure; and in her thirst for power or personal gratification she sometimes cared as little for the purity of the means by which these objects were accomplished.

Character of the Queen-mother. She is made regent. A.D. 1514. Soon after the death of the late king this princess gave birth to a son, who was named Alexander, and created duke of Ross; and in a parliament, which met after her recovery, she was confirmed in the office of regent, and entrusted with the custody of the young king and his brother.

At this moment the most powerful nobles in Scotland were the earls of Angus, Home, Huntly, and Crawford. Angus wielded the whole strength of the house of Douglas; Home was chamberlain, and commanded the eastern borders; while Huntly and Crawford ruled the northern districts. The earl of Arran, in the mean time, arrived from France along with the Sieur de la Bastie, who had been a favourite of the late king, and brought a message from the duke of Albany. Arran was nearly related to the royal family, and entitled, by his high birth, and the office of Lord High Admiral which he held, to act a leading part in the government; but his talents were of an inferior order, and unable to compete with the trying circumstances in which the country was placed.

The Queen-mother marries the Earl of Angus. Scarcely had the queen recovered from her confinement when she married the earl of Angus, a nobleman of great accomplishments and personal attractions, but, in the words of lord Dacre, "childish, young, and attended by no wise counsellors." Had the princess entered into a second marriage after due consultation had been held with the council assigned to her by parliament, and after a decent interval, no one could have blamed her. She was yet in the bloom of her best years, and from her youth, as well as her high rank and the important duties entrusted to her, she required the protection of a husband; but the precipitation with which she hurried into the match with Angus was scarcely decorous, and certainly unwise, nor was it long before she bitterly repented her choice.

The country divided into factions. The first effects of this unfortunate step was to increase the bitterness of the pre-existing feuds amongst the nobles. Home and Angus marshalled themselves and their vassals against each other; Arran, assisted by Lennox and Glencairn, aspired to the regency; Beaton, archbishop of Glasgow, an intriguing prelate, supported the interests of Albany and the French faction; while Huntly, lord Drummond, and the earl Marischal gave their influence to Angus and the queen, who courted Henry the Eighth, and took the name of the English party. At this unfortunate crisis the country received a new blow in the death of Elphinstone, who had been nominated archbishop of St. Andrews. For the vacant primacy there were three competitors; Gawin Douglas, uncle to the earl of Angus, Hepburn, prior of St. Andrews, and Forman, bishop of Moray, respectively nominated by the queen, the chapter, and the pope. These ambitious ecclesiastics scrupled not to muster their armed vassals, and to vindicate their claims by an appeal to the sword, an indecent spectacle, which could not fail to lower the church in the eyes of the people.

It was under this deplorable state of things that Henry the Eighth carried to perfection a base system already be-

gun by his father, that of keeping in pay a number of spies and pensioned supporters. He bribed the Scottish nobles, entertained a constant correspondence with the queen his sister, and even went so far as to propose her flight with the young king and his brother to the English court. It may give us some idea of the loose principles of some of the leading men, that Angus and his uncle, Gawin Douglas, who ranks higher as a poet than a politician, did not hesitate to give their countenance to a plan which amounted to nothing short of treason.

In the midst of these scenes the duke of Albany arrived from France, and assumed the regency; but unfortunately his determined predilection for the French interests was as unacceptable to many of the wisest and best men in the country, as the queen and Angus's devotion to England. At this moment Scotland required an upright and vigorous governor, animated by a sincere love of his country, and who could hold the balance with judgment between contending parties. But Albany was ignorant of the constitution, of the language, and of the manners of the country. His family also made him an object of suspicion, his father having traitorously attempted to seize the crown. He was the son of a French mother, had married a French woman, and having his chief estates in France, constantly styled the French king his master; nor does it appear that either his talents or his temper were calculated to counterbalance such disadvantages.

On his assumption of the government the effects of all this were soon perceived. The queen refused to give up the custody of the infant monarch; Home, the chamberlain, threw himself into the arms of England; Angus, guided solely by selfishness and the ambition of becoming chief ruler, deserted his wife, the queen. France, instead of assisting her ancient ally to defeat the intrigues of Henry the Eighth, which were carried on by his able minister lord Dacre, first betrayed strong symptoms of a change of policy, and at length refused to renew the alliance with Scotland; and although Albany, amid these difficulties, acted with considerable spirit and ability, it was impossible for him to compose the jarring elements, or restore tranquillity and order to the country.

Dissatisfied and dispirited, he retired for a few years to France, and returned to Scotland only to find the dangers which threatened the kingdom more imminent, and the task of encountering them more difficult. In his absence De la Bastie, the person who enjoyed his chief confidence, and to whom he had entrusted the offices of warden of the marches and deputy governor, was murdered by the Homes in the most savage manner. The Highlands and Isles, long deprived of regular government, were torn by various factions, and exhibited scenes of the wildest excesses. And Angus, whose feudal power was far too great for a subject, had acted in open defiance of the laws, and domineered in the most tyrannical manner over all who dared to oppose his commands. The arrival of Albany compelled this chief to fly from the capital, and the regent exerted himself with the utmost vigour to put down the despotism of the Douglasses. He was forthwith reconciled to the queen, received from her the keys of the castle of Edinburgh, and with them the custody of the young king; he assembled a parliament, summoned the Douglasses to answer a charge of treason, and, although thwarted in his administration by the intrigues of lord Dacre and the treachery and venality of the Scottish nobles, he compelled Angus, his principal enemy, to leave the kingdom.

It would be difficult, and if easy, uninteresting, to enter into the history of this period, when the country was torn by contending factions, and exposed to all the miseries incident to a feudal minority. Albany's worst enemies were lord Dacre and the Anglo-Scotic party which he kept in his pay. It was his policy to throw distrust and suspicion up-

Scotland.

Scotland. on every measure of the regent and the queen; to represent the regent as avaricious and tyrannical, to accuse him of a design to seize the crown, and to insinuate that the king's life was not safe in his custody. All of these tales are to be found in his correspondence with his master, Henry the Eighth, and there can be little doubt that the greater portion of them were false, and the whole grossly exaggerated. So at least we must judge from the conduct of the Scottish Parliament, which treated a message, soon afterwards sent by Henry the Eighth, and founded upon these idle accusations, with a calm and resolute denial. This monarch, acting upon the impulse of the moment, and thwarted by the politic

A.D. 1522. measures of the Regent, had dispatched a herald, who conveyed a severe reprimand to the queen, and, at the same time, insisted that the Scottish nobles should instantly dismiss Albany. Their reply to this haughty communication was spirited and dignified. They derided the fears expressed for the life of the young king, declaring that Albany was a faithful servant of the country, and had been invited by themselves to assume the regency. "Here it is our pleasure," said they, "that he shall remain, nor shall he be permitted or enjoined to depart at the request of your grace, or any other sovereign prince. And as to the threat of hostilities, (thus they concluded their answer), if, because we assert our own rights, we should happen to be invaded, what may we do but trust that God will espouse our just quarrel, and demean ourselves, as our ancestors have done before us, who, in ancient times, were constrained to fight for the conservation of this realm, and that with good success and honour?"

War with England. A.D. 1522. This answer was followed, on the part of Henry, by an immediate declaration of war. The earl of Shrewsbury, at the head of the force of the northern counties, invaded Scotland on the side of the Merse and Teviotdale; an English fleet ravaged and laid waste the coasts of the Frith of Forth; and Albany the Regent retaliated by breaking into England at the head of a large army. He was driven to this solely by a desire to vindicate the national honour; for he seems to have been conscious of the disadvantages which attended a war with England, and he knew that the majority of the nobles were animated by the same feelings. Under these circumstances he wisely determined to follow Bruce's principles as to war with this country, to avoid any protracted invasion, not to hazard a general battle, and while he showed a determination to maintain the independence of the country, and to resist any foreign dictation, to evince at the same time his readiness to conclude an honourable peace.

The same disposition being evinced by lord Dacre, the minister to whom Henry entrusted the management of Scottish affairs, a truce was concluded; but Albany, on disbanding his army and resuming his civil duties, found himself surrounded with difficulties. Nothing indeed could be more complicated or irksome, than the various contending interests which he had to understand and reconcile. His engagements with France prompted him to continue the war with England; his better judgment admonished him to remain at peace. Amid the universal corruption and selfishness which infected the body of the nobles, many of whom were in the pay of England, he looked in vain for any one to whom he could give confidence, or entrust with the execution of his designs, while the queen-mother, with whom he had hitherto acted, betrayed him, and corresponded with Dacre.

Albany's second visit to France. The impossibility of overcoming these intricate evils without a more powerful military force than he could at present bring into the field, induced the Regent once more to pass into France, for the purpose of holding a conference with Francis the First, on the best method of reducing the English faction. A council of regency was appointed, consisting of Huntly, Arran, Argyll, and Gonzolles, a French knight, in whom Albany placed great confidence; and after an absence of some months, during which the war again broke out with great fury, he revisited Scotland, bringing

Scotland. with him a fleet of eighty-seven small vessels, in which he had embarked a fine body of six thousand foreign troops.

James V. War with England. A.D. 1523. With this strong reinforcement he hoped to gain a preponderating influence over the nobility, and to decide the contest with England; but he was miserably disappointed. The presence of foreign troops, always unacceptable to a people jealous of their rights, was particularly so to the Scots, who were poor, and had to support the foreigners at a great expense. This rendered the war unpopular with the great body of the nation; the queen-dowager was devoted to England; and the nobles, although prepared to assemble an army for the defence of the borders, were opposed to any invasion of England upon a great scale, or to a war of continued aggression. As many of these barons, however, were at that moment receiving pensions from France, the payment of which any too decided demonstration might have interrupted, they artfully concealed their repugnance. An army of forty thousand men mustered on the Borough-moor beside Edinburgh, and Albany, taking the command in person, advanced to the borders; but on arriving at Melrose the mask was dropped, the leaders showed symptoms of insubordination, the soldiers catching the infection, murmured against the foreign mercenaries, and discontent gathering strength, at last broke out in an open refusal to advance. No entreaties or threats of the Regent could overcome this resolution; and after a short season, news arrived that the earl of Surrey, having assembled an army, was advancing against them. The intelligence of his speedy approach strengthened the Scottish nobles in their determination not to risk a battle. So completely had the majority of them been corrupted by the money and intrigues of Dacre and the queen-dowager, that Albany did not venture to place them in the front, but formed his advance of the French auxiliaries and his artillery, the single portion of this army which had acted with spirit. To have attempted to fight Surrey with these alone, would have been the extremity of rashness, to have awaited the advance of the English earl with an army which refused to proceed against the enemy, might have rendered defeat inevitable. In these critical circumstances, Albany, who has been unjustly attacked by some ill-informed writers, adopted the only alternative which was safe or honourable. He disbanded the Scottish portion of his army, and he himself retreated with his French auxiliaries and his artillery to Eccles, from which, after a short season, he returned to the capital, and here he assembled the parliament.

Albany retreats. Its proceedings, as might have been anticipated, were A Parliament distracted and impeded by mutual accusations and complaints. The Regent could not conceal his animosity to those leaders who had so recently deserted him almost in the presence of the enemy. The nobles recriminated; they blamed him for squandering the public treasure, and notwithstanding the inclement season of the year, insisted on his dismissing the foreign troops, whose residence had become burdensome. All this was calculated to disgust and mortify the governor; and he requested permission to retire once more to France, for the purpose of holding a conference with Francis the First, and inducing him to grant him further assistance against the designs of England. His request was complied with, on the condition that if he did not return to Scotland within a limited period, the league with France, and his own regency, should be considered as at an end. In the mean season, the custody of the king's person was entrusted to the lords Cassillis, Fleming, Borthwick, and Erskine, while the chief management of affairs was committed to a council, composed of the chancellor, the bishop of Aberdeen, and the earls of Huntly and Argyll. Having made these arrangements, the duke of Albany quitted the kingdom, convinced, in all probability, of the impossibility of reconciling the various factions and interests by which it was torn in pieces. Although he gave hopes that his absence

Albany leaves Scotland. A.D. 1524.

Scotland. should not exceed three months, there is strong reason for believing that when he embarked it was with the resolution, which he fulfilled, of never returning to Scotland.

James V.
A.D. 1524.
Revolution
in the go-
vernment.

On the departure of Albany, it soon became apparent that a secret understanding had for some time been maintained between two of the most powerful factions in the country, and that his leaving the kingdom was the signal for the breaking out of an important revolution. The chief actors were the earl of Arran and the queen-mother, and there is ample evidence that their proceedings were agreeable to England. The young king was now in his thirteenth year, and his mother and Arran, having gained to their interest the peers to whom his person had been entrusted, carried him from Stirling to Edinburgh, proceeded to the Palace of Holyrood, declared in a council that he had assumed the government, and issued proclamations in his name. The peers of Margaret's party then tendered their allegiance, abjured their engagements lately made with Albany, declared his regency at an end, and promised to maintain henceforth the authority of their sovereign.

Angus re-
turns from
France.
His base
conduct.

It was the evident object of the queen and Arran to obtain, by this revolution, the entire command of the government. The measure was remonstrated against, in the strongest manner, by the bishops of St. Andrews and Aberdeen. They represented the utter folly of conferring the supreme power on a boy of twelve years old, and they stated, with truth, that Albany was still the Regent; but Margaret, supported by her brother Henry the Eighth, who hoped, through her, to govern Scotland, proved too strong for these prelates, and for a while her schemes succeeded. It was, however, only for a short season. Jealousies arose between her and Arran, who, from his near relationship to the crown, aspired to the chief power. The queen, whose love for Angus, her husband, had long since turned into hatred, fixed her affections on Henry Stewart, a son of lord Evandale, raised him to the office of treasurer, and could she obtain a divorce, determined to marry him; and Henry the Eighth, who began to find her demands too importunate, and her obedience problematical, recalled the earl of Angus from France, with the design of making him an instrument in his projects for the reduction of Scotland. This baron appears to have increased in experience and talent for intrigue, by his residence in that country, but not in public principle; and his first step was to sell himself to Henry in a secret treaty, by which he engaged to support the English interests in Scotland. In return, he and his brother, Sir George Douglas, hoped, by Henry's aid, to place themselves at the head of the government, and to be restored to the vast estates and power which they had lost.

The arrival of Angus in his native country, was the signal for immediate hostilities between him and the queen-mother, his wife, who had raised Henry Stewart to the office of chancellor, and detested her husband, in proportion to the progress of her avowed and indecent attachment to this favourite. Hitherto she and her supporters, Arran, Lennox, and the master of Kilmaurs, had been supported by pensions from the English court, and in return, had favoured the views of Henry the Eighth; but the principles of this venal association were of course capricious and selfish, and the arrival of Angus, who now wielded the power of the Douglasses, threatened to break it to pieces.

Miserable
state of the
country. The country, indeed, presented a miserable spectacle; a minor sovereign deserted by those who owed him allegiance and support, while his kingdom was left a prey to the rapacity of interested councillors, and exposed to the attacks of a powerful neighbour, whose object was to reduce it to the condition of a dependant province. In such circumstances it is certainly a matter of wonder that it retained its liberty.

Three factions struggled for the pre-eminence, and tore the country in pieces. The first was that of Albany, the late

VOL. XIX.

regent, which was supported by French influence, and conducted by the chancellor Beaton; the second had for its leaders the earl of Arran and the queen-regent, who held the king's person, and possessed the chief executive power; at the head of the third were the earl of Angus and his able brother George Douglas, who were wedded to the interests of the English government. It is impossible, within our limits, and it would be un instructive, to enter into a detail of the continued plots and intrigues which constitute the sickening history of this period. It soon became apparent that the party of the queen-mother was the weakest. Arran, a capricious man, deserted her; her private conduct rendered her disreputable in the eyes of the people; and soon afterwards a coalition between Beaton the chancellor and Angus, carried the whole power of Albany's party to a union with the house of Douglas. Margaret sunk under this, and consented to a negotiation. She resigned the custody of her son to a council of peers nominated by parliament, and, stripped of her power, consented to a reconciliation with Angus, her husband, in whom, along with the chancellor Beaton, the chief power in the government now centered. A feeble effort indeed was made by Arran to destroy the influence of the united factions; but the armed force with which he advanced to Linlithgow was dispersed by the prompt attack of Douglas, and the address of this politic baron soon afterwards prevailed on Arran to join his party.

Angus ob-
tains pos-
session of
the king's
person.

The earl of Angus had now gained a complete triumph over his enemies. He possessed the person of the young king, he was assisted by the talents and experience of the chancellor Beaton, he had witnessed the gradual decay of the faction of Albany and the French monarch, and he had been joined by Arran, who, although personally a weak man, from his high birth and great estates possessed much power. His first step was wise and temperate. A pacification for three years was concluded with England; and it was hoped that this might be followed by a marriage between the young king and Henry's daughter, the princess Mary, a measure which, if guarded so as to preserve the independence of Scotland, might have been attended with the happiest results.

The country, so long distracted by border war and internal anarchy, might now, under a judicious administration, have looked forward to something like tranquillity. Had Angus been reconciled to the queen, his wife; had he been contented with his recovery of greater power than he had lost, and been willing to administer the government with justice and moderation; there was every reason to hope for the maintenance of peace, security, and good order. The French party in Scotland had completely sunk. Dr. Magnus, Henry's English minister, who, during his residence in Scotland, had been an object of great jealousy to the people, was recalled; and lord Dacre, whose money and intrigues for so many years had corrupted the Scottish nobles, and introduced disunion and treachery into all their councils, was removed by death from the scenes of his mischievous activity. All these things were favourable; and the well affected, who sighed for the blessings of peace and good government, anticipated a period of repose.

Decay of
French in-
fluence in
Scotland.

It was a vain expectation, destroyed by the precipitate Marriage of the queen-mother, and the grasping ambition of the great object, which he now deemed himself on the very point of attaining: to accomplish a reconciliation with his wife, the queen-mother, and, possessing her estates, with the custody of the young king's person, to engross the whole power of the government. At this crisis Margaret, so far from becoming less hostile to Angus, gave herself up more inconsiderately than before, to her passion for Henry Stewart, and procuring a divorce from a husband whom she hated, espoused her paramour with a precipitation which disgusted the people.

James V.
A.D. 1526.
Angus's
intrigues.
The secret
council an-
nulled.

This imprudent step determined Angus to change his ground, and a dread of some counter revolution threw him upon new and more violent courses. By a successful stroke of policy, he procured the passing of an act of Parliament which annulled the authority of the secret council, the only power which stood between him and absolute dominion. At the same moment, the parliament declared that the minority of the young king was at an end, and that having completed his fourteenth year, he was to be considered as an independent sovereign. While the youthful monarch thus nominally assumed the government, that provision which entrusted the keeping of the royal person to certain peers in rotation, remained in force; and as Angus had artfully summoned the parliament at that precise time, when it belonged to himself and the archbishop of Glasgow to assume their periodical guardianship of the king, the consequence of this state manœuvre was to place the whole power of the government in their hands.

The king's
minority
declared at
an end.

A new secret council was nominated, composed solely of the creatures of Angus; the great seal was soon after taken from Beaton, the young king was watched with the utmost jealousy, and compelled to give his consent to every thing proposed to him by his new masters. An act of parliament was passed, granting a remission to the heads and followers of this all-powerful faction for the crimes, robberies, or treasons, committed by them during the last nineteen years; every office of trust or emolument in the kingdom was disposed of to the one or other of its supporters, and the ancient tyranny of the house of Douglas once more attained a degree of strength which rivalled, or rather usurped the royal power. At this unhappy period, as has been observed in another work, "the borders became the scene of tumult and confusion, and the insolence of the numerous vassals of this great family was intolerable; murders, spoliations, and crimes of varied enormity, were committed with impunity. The arm of the law, paralysed by the power of an unprincipled faction, neglected to arrest the guilty; the sources of justice were corrupted; the highest and most sacred ecclesiastical dignities became the prey of daring intruders, or were sold to the highest bidder; and the young king, carried about through the country by Angus, apparently in great state, but merely a puppet in the hands of his masters, sighed in vain over a captivity to which there appeared no prospect of a termination."¹ An attempt indeed was made for his deliverance, first by the laird of Buccleugh, one of the most powerful of the border barons, and afterwards by the earl of Lennox, who deserted the party of the Douglasses, and to whom the young monarch was much attached. But Buccleugh was routed with considerable loss, and Lennox defeated and slain.

Angus

Henry
VIII.
General re-
marks.

These unsuccessful attempts only strengthened the power of Angus. He entered into a more strict alliance with Henry the Eighth, obtained the friendship and support of Beaton, the archbishop of St. Andrews, and unchecked by any opposition, ruled all things at his will. Nothing indeed could be more miserable than the picture presented by the country; a monarch in captivity, a nobility in thraldom, a people groaning under the most complicated oppressions, yet with their hands tied, and compelled by the miserable system under which they lived to serve their oppressors. It may be asked, what was the secret history of this enormous power, this degraded and implicit obedience? The answer is to be found in the fact, that the Douglasses were masters of the royal person; they could compel the king to affix his signature to any deeds or letters which their tyranny or their caprice might dictate. Angus, the supreme lord of all this misrule, was chancellor, and the great seal at his command; his uncle, Douglas of Kilspindie, was treasurer, and commanded the whole revenues of the country;

the law, with all its terrible feudal processes of treason and forfeiture, could be wielded by them at pleasure. So long as the king remained in their hands, this powerful machinery was all theirs; the moment he escaped, the system broke to pieces, and their power was at an end.

Scotland.
James V.
A.D. 1528.

Of all this James, who had now entered his seventeenth year, was perfectly aware; and as every hour of his captivity made the Douglasses more hateful to him, his mind became intently occupied with projects for his escape. Nor was it long ere he effected it. With an address superior to his years, the king had either succeeded in lulling the suspicions of his keepers, or a continuance of unchecked power had made them careless. James was at Falkland. Angus, Douglas his brother, and Archibald his uncle, were absent on their private affairs; only Douglas of Pathhead, the captain of the royal guard, remained. The young monarch called for the park-keeper, and, as had been his wont, proposed to hunt next morning. Therefore, says a graphic old chronicler,² he "caused him to warn all the whole tenants and gentlemen thereabouts who had the speediest dogs, that they would come to Falkland wood on the morn, to meet him at seven hours, for he was determined he would slay a fat buck or two for his pleasure; and to that effect caused warn the cooks and stewards to make his supper ready, that he might go to his bed the sooner, and to have his *desjeune* (breakfast) ready by four o'clock, and commanded James Douglas of Pathhead to pass the sooner to his bed, and caused bring his collation, and drank to James Douglas, saying to him, that he should have good hunting on the morrow, bidding him be early astir. Then the king went to his bed; and James Douglas, seeing the king in his bed, wist that all things had been sure enough, and passed in like manner to his bed. When the watch was set," continues Pitscottie, "and all things in quietness, the king called on a yeoman of the stable, and desired him bring one of his suits of apparel, hose, cloak, coat, and bonnet, and putting them on, slept forth as a yeoman of the stable, and was unperceived of the watches, till he had passed to the stables, and caused saddle a horse for himself, and one led, and took two servants with him, namely, Jocky Hart, a yeoman of the stable, and another secret chamber boy, and leapt on horse, and spurred hastily his journey to Stirling, and won there by the breaking of the day, over the bridge, which he caused to be closed behind him, that none without licence might win that passage. After this he passed to the castle, and was received there by the captain, who was very glad of his coming, and prepared the castle with all things needful. Then he caused shut the gates, and let down the portcullis, and put the king in his bed to sleep, because he had ridden all that night."

Having thus regained his liberty, James's first act was to summon a council, and issue a proclamation, interdicting the Douglasses from all approach within six miles of the court, under pain of treason. Nor did they venture to disobey it. On discovering the flight of the king, Angus, Archibald, and Sir George, had hastily assembled a few followers, thrown themselves on horseback, and were riding to Stirling, when they were met by the herald, who read the act, and commanded them in the king's name to halt. For a moment they hesitated, but it was only for a moment. Their sovereign was free; the weapons which but a day before they had wielded with such irresistible force, were now ready to be employed against themselves. A single step forward, and they were guilty of treason, their property and their lives at the mercy of the crown. All this rose rapidly and fearfully before them; and aware how vain it would be at such a moment to meet the power of their enemies, they retreated to Linlithgow.

The monarch, who now took the government into his own

¹ Tytler's History of Scotland, vol. v p. 201.

² Lindsay of Pitscottie, pp. 218, 219.

Scotland. hands, had not completed his seventeenth year; but he had been nursed in the school of difficulty, and his character had acquired a consistency and vigour far superior to his age. This was the more to his credit, because the Douglasses had neglected his education; and while they gave him no opportunities of cultivating the qualities which might have made him a blessing to his people, permitted him to indulge in that love of pleasure and tendency to dissipation which was incident to his temperament and time of life. Happily his character, although it did not escape the pollution of such a base system, survived it; and, with some great faults, the king possessed at the same time not a few of the highest qualities which became a wise and good prince. Strict and scrupulously just, unwearied in his application to business, earnest in his endeavours to remove the complicated burdens which, under the tyranny of the late oligarchy, had oppressed the people; generous, though somewhat warm in his temper, easy of access, a stranger to pride, and fond, almost to a fault, of mingling familiarly with all classes of his subjects; he soon rendered himself, young as he was, an object of respect to his nobles, and of affection to his people.

Principles of James's government. The principles which regulated his future government sprung naturally from the circumstances of his early life. The sternest resentment against Angus and the house of Douglas, was combined with a determination to assert and regain the rights of the crown, and to abridge the power of an aristocracy, which had grown intolerable during a long minority. Towards his uncle, Henry the Eighth, it was impossible that his feelings could be any other than those of resentment and suspicion. It was by this prince that there had been introduced into Scotland an organised system of corruption, of which his able and unscrupulous minister, lord Dacre, had been the author. Many Scottish nobles had become the pensioned agents of the English government; paid informers swarmed in the court and through the country. All idea of conquering Scotland by force of arms had been long since abandoned; but a more insidious expedient was adopted, by which the English king, maintaining the Douglasses in their usurped dominion, received in return their homage and fidelity, and administered the government at his pleasure.

James's great objects, which we can trace through the whole remaining period of his reign, were to put an end to this system of foreign dictation; to restore its ancient and constitutional prerogatives to the crown; to bridle the exorbitant power of the great nobles, raising up as a check upon them the large and influential body of his clergy; to encourage the mercantile and commercial classes of his people; and to facilitate the administration of the laws, and insure equal justice to the lowest orders of the community.

Proceedings against the House of Douglas. For the accomplishment of such ends, it was first necessary to exhibit a wholesome example of retributive justice upon those who had been the greatest delinquents. It was declared treason for any person to hold intercourse with Angus, and every Douglas was commanded to leave the capital on pain of death. Angus himself was commanded to remain beyond the waters of the Spey, and required to deliver his brother Sir George Douglas, and his uncle Archibald, as hostages, for his answering to his summons of treason. Having haughtily disobeyed these orders, a parliament assembled. He was proclaimed a traitor, and his lands nominally divided among those nobles to whom James owed his late success. It was easier, however, to promulgate than to execute such decrees against so powerful a baron; nor was it till after repeated attacks upon Tantallon, some of them led by the king in person, that the arch-offender was reduced, and compelled to seek an asylum in England.

James next directed his attention to the state of the borders; and in an expedition which was long remembered for the vigour, dispatch, and severity of the royal vengeance,

Scotland. inflicted punishment upon the greatest offenders, among whom was the noted freebooter, Johnnie Armstrong, and reduced the district into a state of tranquillity. Scarcely was this accomplished, when the Orkneys were threatened to be torn from the crown by the rebellion of the earl of Caithness; and the Isles became the scene of a fierce struggle between the earl of Argyll and Alexander of Isla, one of the most powerful chiefs of that remote region. The judgment and energy of the monarch were shewn in the speedy re-establishment of peace in both quarters; and the people, aware that the sceptre was once more in a firm hand, readily and gratefully co-operated with their sovereign in all his labours.

England and France were now at peace, and Henry the Eighth and Francis the First united in a strict alliance, which had for its object to bridle the increasing power of the emperor Charles the Fifth. Under these circumstances, Henry proposed a matrimonial alliance with Scotland, and the design was encouraged by France; while the emperor, jealous of the power which so near a connexion with James might give to his enemies, offered in marriage to the young prince his sister, the queen of Hungary, or his niece, the daughter of Christiern, king of Denmark, with Norway as her dowry.

For the present, however, all these offers were declined, and the monarch appeared wholly engrossed with the prosecution of his various plans for the melioration of his kingdom. Finding himself thwarted by the nobles, he was compelled to adopt decided measures, and to promote the clergy to those offices which had been filled by temporal barons. Argyll was thrown into prison, the earl of Crawford stripped of a large part of his estates; the determination that no Douglas should ever bear sway in Scotland became a more stern and obstinate principle than before; and while the archbishop of Glasgow, the abbot of Holyrood, and the bishop of Dunkeld, were principally consulted in affairs of state, many of the nobles who had hitherto enjoyed the royal confidence saw themselves treated with coldness and distrust.

It was at this time, that the king carried into effect two important measures, the one affecting the commercial interests of his kingdom, the other of still higher moment, as an endeavour to secure to all classes of his subjects an equal and speedy administration of justice. A commercial treaty between Scotland and the Netherlands had been concluded by James the First, for the period of one hundred years. It was now approaching its termination, and an embassy was dispatched to Brussels, which renewed the league for another century. His second measure was the institution of the College of Justice, a court consisting of fourteen judges, one half selected from the spiritual, the other from the temporal estate, of which the idea is commonly believed to have been suggested by the parliament of Paris. The principal design of this new judicature was to put an end to the delay and partiality arising out of the barons' courts; in other words, to remove the means of oppression out of the hands of the aristocracy; but as it was provided, that the king might at his pleasure send three or four members of his council to give their votes, it was evident that the subject was freed from one grievance, only to be exposed to the hazard of another, whenever his rights might happen to come in collision with the crown.

During these transactions, the Douglasses and their adherents were driven upon violent and discreditable courses, in proportion as their prospect of reconciliation to the king became more hopeless and remote. The earl of Bothwell, also a powerful border baron, whose excesses James had severely punished, entered into a traitorous alliance with Henry the Eighth, in which he engaged, if properly supported, to dethrone his sovereign, and to "crown the English king in the town of Edinburgh within a brief time;"

Institution of the College of Justice.

The Douglasses sell themselves to England.

Scotland. while the earl of Angus did not hesitate, in the extremity of his resentment, to sell himself to England; and in an original writing which yet remains, engaged to "make unto Henry the oath of allegiance, to recognise him as supreme lord of Scotland, as his prince and sovereign."¹

War with England. A.D. 1532. Henry VIII. and the Douglasses invaded the country. In consequence of these base engagements, war was once more kindled on the borders, and carried on by the Douglasses and Henry's captains with such desolating fury, that James was compelled to call out the whole body of the fighting men in the country. These he divided into four armies, to each of which in rotation the defence of the marches was entrusted. The measure effectually checked the power of the English, and there was little prospect of Bothwell fulfilling his threat, of crowning Henry in the capital; but peace seemed more distant than ever, and nothing could be more deplorable than the picture presented by the country. The flames of villages and granges, the destruction of the fruits, and the cessation of the labour of the husbandman, the stoppage put to the enterprise of the merchant, the increase among the people of the spirit of national antipathy, the corruption of the nobles by the money of England, the loss among such pensioned adventurers of all affection for the sovereign, and the decay of the healthy feelings of national independence; all these lamentable consequences sprung out of the continuance of the war, and made the king desirous of securing peace, even if it should be at some sacrifice.

Peace with England. This he at length accomplished. James agreed that the Douglasses, by which was meant Angus, his brother George, and his uncle Archibald, should remain unmolested in England, supported by Henry as his subjects, on condition that Edrington castle, the only spot which they held in Scotland, should be surrendered, and reparation made for any expedition which they or the English king might hereafter conduct against Scotland. On these conditions a pacification was concluded, for the period of the lives of Henry and James, and a year after the death of him who first deceased; and soon after its ratification, the young monarch, whose firmness and talent in the management of his government made him an object of respect to the European princes, received the Garter from England, the order of St. Michael from France, and the Golden Fleece from the emperor.²

James was now in his twenty-second year, and his marriage was earnestly desired by the country; but he had hitherto shewn little inclination to gratify the wishes of his people. With all his good qualities, he unhappily inherited from his father an extreme devotedness to pleasure, which had been rather encouraged than restrained by the Douglasses; and his passions getting the better of his prudence and principle, sought their gratification in low intrigues, carried on in disguise, and in pursuit of which he not unfrequently exposed his life to the attacks and revenge of his rivals. It was now full time that he should renounce these disreputable excesses; and having evaded an offer made by the Spanish ambassador, of the hand of the princess Mary of Portugal, and declined a similar proposal of Henry the Eighth, who pointed to his daughter the princess Mary, he dispatched an embassy to France, for the purpose of concluding a matrimonial alliance with that crown.

The Reformation. It now becomes necessary to attend to a great subject, (the rise of the Reformation in Scotland,) the principles of which had been for some time silently making their progress among the people, but which from this period exercised a marked and increasing influence over the history of the government and of the country. It was now nearly six years since Patrick Hamilton, abbot of Ferne, the friend and disciple of Luther and Melancthon, having renounced the errors of the Roman Catholic church, and embraced the doctrines of these leading reformers, had been delated

of heresy, and condemned to the flames. The cruel sentence was carried into effect at St. Andrews in 1528, under the minority of James, and while the supreme power was in the hands of the earl of Angus. On taking the government into his own hand, James, although decidedly inimical to the principles of Angus in all other things, unhappily followed his determination to persecute those whom he esteemed the enemies of the truth. David Straiton and Norman Gourlay, who were disciples of the reformation, were tried for heresy, condemned, and brought to the stake, on the 27th of August 1534; and the intolerant and cruel conduct of the king compelled some who had embraced the same opinions to fly for safety to England.

About this time Henry the Eighth exerted himself to the utmost to prevail upon the Scottish king to imitate his own conduct, and shake off the yoke of Rome. He endeavoured to open his eyes to the tyranny of the pope's usurpations, sent to him the treatise entitled the "Doctrine of a Christian Man," and dispatched Dr. Barlow and Lord William Howard to request a conference with his royal nephew at York; but the remembrance of the injuries he had sustained, resentment for Henry's intrigues with his discontented subjects, and an attachment to the faith of his fathers, indisposed James to listen to these overtures; and when Paul the Third deputed his legate Campeggio to visit Scotland, the embassy found it no difficult matter to confirm the Scottish monarch in his attachment to the Catholic church. At the same time he addressed him by the title of which Henry had proved himself unworthy, Defender of the Faith, and presented to him a cap and sword which had been consecrated by the pope upon the feast of the nativity.

A parliament which assembled about this time, made two provisions which deserve attention. The importation of the works of Luther, which had been proscribed by a former act, was again strictly forbidden; any discussion of his opinions, unless for the purpose of proving their falsehood, was prohibited; and all persons who possessed any treatises of the reformer, were enjoined, under the penalty of confiscation and imprisonment, to deliver them up to the ordinary within forty days. The second act, which is well worthy of notice, related to the boroughs, in this dark age the best nurseries of industry and freedom. Hitherto feudal barons had been elected to the offices of magistrates and superintendents over the privileges of these corporations; an unwise practice, by which the provosts, aldermen, or bailies, instead of being industrious citizens, interested in the protection of trade, and the security of property, were little else than idle and factious tyrants, who consumed the substance and invaded the corporate privileges of the burghesses. A law was now made, that no person should be elected to fill any office in the magistracy of the borough, but such as themselves were honest and substantial burghesses, and although not immediately or strictly carried into effect, the enactment evinced the dawning of a better spirit.

War still continued between Francis the First and the emperor, a circumstance which induced the French king to continue an amicable correspondence with England; and being aware that Henry the Eighth was intent upon accomplishing a marriage with Scotland, Francis did not care to disgust this passionate monarch by any very speedy attention to James's desires to unite himself to a French princess. To obviate this, the Scottish king himself took a voyage to France, and landing at Dieppe, proceeded from thence in disguise to the palace of the duke of Vendôme. Here, being received only as a noble stranger, he saw, for the first time, but did not approve of his affianced bride, Marie de Bourbon, the duke's daughter, and transferred his affections to Madeleine, the youngest daughter of the French king, to

¹ MS. British Museum, Calig. B. I. 128.

² Diurnal of Occurrents in Scotland, p. 19

Scotland. whom he was soon after married in the church of Notre Dame. In the circumstances in which Scotland was then placed, the church of Rome was inclined to consider this union as one of great importance; and it has been noted that seven cardinals surrounded the altar. Nor were these anticipations disappointed. James remained for nine months in France, and having returned to his own kingdom, it was soon evident that some great changes were on the eve of taking place.

Rupture between Francis I. and Henry VIII. Francis the First, although still nominally at peace with Henry, had become alienated from him by the violent and dictatorial tone which he assumed. The pope, who considered his own existence as involved in the contest with England, had neglected no method by which he might first terminate the disputes between the emperor and the French king, and then unite them in a coalition against Henry, as the common enemy. We have already noticed the success of the court of Rome in flattering the vanity of James; and it appears that, in 1537, these intrigues were so far successful, that a pacification was concluded between Francis and the emperor. From this moment the cordiality between France and England was completely at an end, while every argument which could have weight in a young and ardent mind was addressed to James, to induce him to join the projected league against Henry.

Mission of Sir Ralph Sadler to Scotland. Nor had the conduct of Henry, during James's absence in France, been calculated to allay those resentful feelings which already existed between them. He had sent into Scotland Sir Ralph Sadler, a crafty and able diplomatist, for the express purpose of completing the system of secret intelligence introduced, as we have seen, with pernicious success by lord Dacre. This minister was instructed to gain an influence over the nobility, to attach the queen-mother to his interest, to sound the inclinations of the body of the people on the subject of peace or war, an adoption of the reformed opinions, or an adherence to the ancient faith. The Douglasses were still maintained with high favour in England. Their power, although nominally extinct, was far from being destroyed; their spies penetrated into every quarter, and had even followed the young king to France, whence they gave information of his most private motions; finally, those feudal covenants, termed bonds of manrent, still bound to their interest many of the most potent of the nobles, whom the vigour of the king's government had disgusted or estranged.

From this description we may gather the state of parties at the return of James to his dominions after his marriage. On the one hand was seen Henry the Eighth, the head of the protestant reformation in England, supported in Scotland not only by the still formidable power and unceasing intrigues of the Douglasses, but by a large proportion of the nobles, and the talents of his sister, the queen-mother. On the other hand stood the king of Scotland, assisted by the united talent, zeal, and wealth of the Roman Catholic clergy, the loyalty of some of the most potent peers, the co-operation of France, the approval of the emperor, the affection of the great body of his people, upon whose minds the doctrines of Luther had not yet made any very general impression, and the cordial support of the papal court. The course of events, into which we cannot enter minutely, but which we shall touch in their principal consequences, illustrated strikingly these opposing interests.

James's second marriage. In the mean time, scarcely had the rejoicings ceased for James's return to his dominions with his youthful queen, when it was apparent that she was sinking under a consumption, which in a short time carried her to the grave. Although depressed by this calamity, the king did not permit it to divert his mind from that system of policy on which he had resolved to act: and an embassy to France,

Scotland. was entrusted to David Beaton, afterwards the celebrated cardinal, who requested for his master the hand of Mary of Guise, the widow of the duke of Longueville, and sister to James V. the cardinal of Lorraine. To this second union, the court of France joyfully assented and the marriage took place at St. Andrews, within a year after the death of the former queen. At this moment the life of the king was twice endangered by conspiracy; and although much obscurity hangs over the subject, both plots were probably connected with the intrigues of the house of Douglas. At the head of the first was the master of Forbes, a brother-in-law of Angus. The chief actor in the second was the lady Glamis, his sister, who, only two days after the execution of Forbes, was accused of an attempt to poison her sovereign, found guilty and condemned to be burned; a dreadful sentence, the execution of which she bore with the hereditary courage of her house.

An event now happened, which drew after it important consequences. James Beaton, archbishop of St Andrews, died, and was succeeded in the primacy by his nephew, cardinal Beaton; a man far his uncle's superior in talent, and still more devotedly attached to the interests of the Roman Catholic church. It was to him, as we have seen, that James had committed the negotiation for his second marriage; and so great appears to have been the influence which he acquired over the royal mind, that the king henceforth selected him as his principal adviser.

Beaton's accession to additional power was marked by a renewed persecution of the reformers; and it is worthy of observation, that most of the converts to the reformed faith belonged to the order of the inferior clergy. Keillor, Forret, Simson, and Beveridge, were arraigned before an ecclesiastical tribunal, and soon afterwards Kennedy and Russell, out of which number three, Kennedy, Forret, and Russell, suffered at the stake with great meekness and courage. There can be little doubt that such inhuman executions operated in favour, rather than against the progress of the reformation.

The coalition between Francis the First and the emperor was now completed under the auspices of the papal court; and Henry the Eighth, aware of the great efforts made to induce James to join the league against him, dispatched Sir Ralph Sadler into Scotland. The object of this able negotiator was to rouse James's jealousy against the increasing power of the clergy, to prevail upon him to throw off his allegiance to the pope, to imitate his example by suppressing the monasteries, and to urge him to maintain the peace with England. To the last request the Scottish king replied, that if Henry's conduct was pacific, nothing should induce him to join any hostile league against him; but he assured Sadler that he found his clergy his most loyal and useful subjects; and although he would be anxious to see a reformation in the general morals of this body, he did not exactly see how that could best be effected by renouncing the authority of his holy father the pope, the terrestrial head of the church, and thus setting an example of rebellion and confusion.

James had for some time meditated an important enterprise, which he now executed; a voyage to the most northern parts of his dominions conducted by himself, and on a scale such as had not been attempted by any of his predecessors. His fleet consisted of twelve ships, fully armed and provisioned. He was attended by Beaton, and the earls of Huntly, Arran, and Angus; and these barons bringing with them their armed vassals, formed a force which, united to the royal suite and attendants, was equal to a little army. Lindsay, a skilful hydrographer, accompanied the expedition, and his maps and charts, the first rude essays in this science ever attempted in Scotland, are preserved at the present day.¹ The king first coasted Fife, Angus, and

¹ In the Harleian Collection, British Museum.

Scotland. Buchan; he next visited Caithness, crossed the Pentland frith to the Orkneys, doubled Cape Wrath, steered for the Lewis, crossed over to Skye, circumnavigated Mull, swept along the shores of Argyle, and passing Kintyre, inspected Arran and Bute, whence he sailed up the Clyde to Dunbarton, where he concluded his labours.

The effects of this royal progress were salutary and decisive. The force with which James was accompanied secured a prompt submission to his commands, and inspired these remote districts with a wholesome dread of the royal name. Some of the fiercer and more independent chiefs, who affected a show of resistance, were seized and confined in irons on board the fleet; others, more gently treated, were yet compelled to accompany the monarch as hostages for the pacific behaviour of their followers; and all were convinced that any attempt to brave the power of the crown, must for the present be vain and ruinous.

Conspiracy against the king's life. This exhibition of increasing energy in the king only exposed him the more to the jealousy of those nobles whose power had been nourished by long intervals of license, and who now clearly perceived, that unless they were prepared to resign their rights, a struggle between them and their sovereign could hardly be averted. A proof of this was shown on James's return to court from his northern voyage, when a conspiracy against his life was detected, the third which had occurred within no very long period. Like the rest it is involved in obscurity; but the proof was considered as sufficient, and its author, Sir James Hamilton, commonly called the bastard of Arran, was tried, convicted and executed. It is said that the king was thrown into a state of great despondency and gloom by the discovery of this plot; that it opened his eyes to the manifold dangers which surrounded a prince at variance with his nobles; and that he began to feel that he was engaged in a contest in which they might prove too strong for him.

A parliament. James's decided measures. Whatever credit we may attach to these reports, the conduct of James gave decided proofs that he was determined to continue the struggle; and in a Parliament which soon afterwards assembled in the capital, he strengthened his own hands by annexing to the crown the whole of the Hebrides, by which we are to understand the isles north and south of the two Kintyres. But this was not all. To these new acquisitions were added the Orkney and Zetland isles, many extensive lordships, Jedburgh forest, and the demesnes of Angus, Glamis, Liddaldale, and Evandale.

In the want of contemporary evidence, it is difficult to decide upon the strict justice of this sweeping measure. It is possible that, by rigidly investigating the history of former rebellions, and present treasons, James may have persuaded himself that he was entitled to the forfeiture of all these large estates and principalities; but in such circumstances it had been the practice of former monarchs to parcel out the forfeited lands among his nobles who had preserved their loyalty; and in the measure now adopted, of annexing the whole to the crown, the aristocracy saw little else than their own intended ruin. It was in vain that the measure was followed by the publication of a general act of amnesty for all former treasons. The earl of Angus, Sir George Douglas, and the whole of their adherents were excepted; and men observed that while the king's generosity was vague and capricious, his aversion to those who had once injured him, was stern and immutable.

The king's conduct regarding the Reformation. It is not easy to discover James's exact opinions regarding the progress of the reformed doctrines, which now began to create great alarm in the Roman Catholic clergy. On the one hand he seems to have become convinced of the necessity for a reform in the church, and to have looked with a severe eye upon the idleness, corruption, and ignorance of a large portion of the clergy. He encouraged Sir David Lindsay, whose satire upon the three estates contained a bitter attack upon the prelates; and being himself much in-

involved in debt, there is reason to believe he regarded the Scotland. overgrown possessions and extraordinary wealth of the clergy with certain longings to appropriate some portion of it towards the exigencies of the state. Yet, in the Parliament to which we have just alluded, it was made a capital offence to argue against the supreme authority, or the spiritual infallibility of the pope; the discussion of religious questions in private meetings was interdicted; a law was passed against the demolition of the shrines and images of saints; and it was evidently the opinion of the king that the reformation should be made by the church itself, within itself, and under the sanction of its head the pope.

Such seems to have been the feelings and the policy of the sovereign. Those of another influential body in the state, the clergy, are easily detected. To counteract the intrigues of Henry the Eighth, and to check any incipient feelings of favour towards the reformation, the great reliance of cardinal Beaton and the Roman Catholic party was in the prospect of a war with England. To accomplish this, they had unfortunately ample materials to work upon. Henry the Eighth was violent and dictatorial; James proud, and jealous of his independence. The English king had espoused the interests of the banished house of Douglas, and fomented discontent among the rest of the Scottish nobles. James was animated by an unrelenting animosity to the earl of Angus, the head of the house of Douglas, and to all who bore the name. Henry, instigated by the utmost hostility to the Roman see, eagerly desired that his royal nephew should imitate his example, suppress the religious houses, and proclaim his independence; but the instructions to his ambassador, Sadler, upon this subject, contained expressions so personally insolent to James, that if obeyed, his mission must have occasioned disgust rather than conciliation. The English king requested a personal interview at York; and James, after a promise to meet him, broke the appointment with Henry, who had proceeded to that city in expectation of his arrival.

At this crisis, the Scottish king evidently dreaded being prematurely hurried into war. He was in debt, he suspected the fidelity of his nobles, he was well aware that a feudal monarch at variance with his barons, the sinews of his strength, was likely to be dishonoured and defeated. He had lately lost his only children, Arthur and James, and he believed that Beaton's anxiety for war was dictated by selfish motives, and influenced by his intrigues with Rome. Under these circumstances, public policy and personal feeling alike made him dread any immediate hostilities with England, and he endeavoured by an embassy to avert the rupture; but Henry, from the moment of his disappointment at York, would listen to no message of conciliation. War was resolved on, the east and middle marches were put into a state of defence, Berwick inspected, musters raised in the north, and soon afterwards Sir James Bowes, with the force of the east marches, marched across the border. The banished Angus, his brother Sir George Douglas, and a large body of the retainers of the Douglasses, had joined him; but they were encountered, and completely defeated by Huntly and Home.

This, however, was merely a preliminary outbreak; and as such border outrages had frequently occurred without drawing after them more serious consequences, James made a last effort to avert the storm, by sending commissioners first to York, and afterwards to meet the duke of Norfolk, who, at the head of an army of forty thousand men, had crossed the Tweed, and already given many of the granges and villages to the flames. It was in vain, however, to attempt negotiation; and aware that the crisis had arrived, the Scottish king commanded Huntly and Home, upon whose fidelity he had most reliance, to watch the progress of Norfolk, while he himself assembled the main force of his kingdom on the Borough-moor near Edinburgh.

Scotland.

James V.
A.D. 1542.
James resolves on war.

The nobles refuse to invade England.

With this army, which mustered thirty thousand strong, he advanced to Fala-moor, and when encamped there, received the welcome intelligence that Norfolk, compelled by the want of supplies and the severity of the winter, was in full retreat. It was now the time to retaliate, and James issued orders for an immediate invasion of England. But the nobles felt their own strength. They had long regarded the measures of the court with distrust, some even with indignation and a desire of revenge; they recalled to mind the proceedings of the monarch, the threatening attitude lately assumed by the crown towards the whole body of the aristocracy; and when commanded to cross the borders, they haughtily and unanimously refused. It was in vain that James, stung with such an indignity, threatened, remonstrated, and even entreated them, as they valued their own honour and his, to proceed against the English. The feeling of attachment to their prince, or revenge against the enemy seemed to be completely extinguished in a resolution to assert their power, and procure a redress of their grievances; and the sovereign was at last compelled to disband the army, and return outbraved and defeated to his capital.

He assembles a second army. The Scots entirely routed by the English.

A.D. 1542.

There can be no doubt that so mortifying a reverse sunk deep into the heart of James, but his pride, and the natural vigour of his character supported him. Though deserted by the majority, he had still some powerful friends among the nobles, the clergy were unanimously in his favour, and it was resolved to make a second effort to re-assemble the army for the invasion of England. Its success, though partial, once more gave a gleam of hope to the monarch. A force of ten thousand men was collected chiefly by the exertions of Lord Maxwell; with this it was resolved to break across the western marches, and the king took his station at Caerlaverock, where he eagerly awaited the result of the expedition. A distrust of his nobles, however, still haunted him; and secret orders were issued, that as soon as the army reached the river Esk, his favourite, Oliver Sinclair, should be intrusted with the chief command. Nothing could be more unwise than this resolution. It was received with murmurs of discontent; and when the new general exhibited himself to the camp, and a herald attempted to read the royal commission by which he was appointed, the whole army became agitated, disorderly, and almost mutinous. At this crisis, Dacre and Musgrave, two English officers, advanced to reconnoitre at the head of three hundred horse, and approaching near enough to perceive the condition of the Scots, boldly charged them. The effect of this surprise was instantaneous and fatal. Ten thousand Scots fled from three hundred English cavalry, with scarcely a momentary resistance. In the panic the greater number escaped, but a thousand prisoners were taken, and among them many of the leading nobles, Cassillis, Glencairn, Maxwell, Somerville, Gray, Oliphant, and Fleming.

The king dies of a broken heart.

This second calamity completely overwhelmed the king. He had eagerly awaited at Caerlaverock the first news from the army, and he anticipated a victory which should efface the late dishonour, and restore the feelings of cordiality between himself and his barons. In an instant the hope was blasted, and gave place to the most gloomy despondency. For their unheard-of conduct, James could find no solution but in the persuasion that his nobles had secretly conspired to betray him to England, and to sacrifice the independence of the kingdom to the gratification of their personal revenge. This idea preyed upon his mind. The feeling that his army had exposed themselves, their sovereign, and the Scottish name to contempt, took entire possession of him. He became the victim of a low fever, which had its seat in a wounded heart, and from a proud monarch, lately in the vigour of his strength and the prime of his age, he sunk into a state of silent melancholy. When in this hopeless condition, the news arrived that his queen had given birth to a daughter.

He had already lost his two sons, and clung to the hope that his next might be a boy. But here too he was met by disappointment; and wandering back in thought to the time when the daughter of Bruce brought to his ancestor, the steward of Scotland, the dowry of the kingdom, he received the intelligence with the melancholy remark, "It cam wi' a lass, it will gang wi' a lass." "It came by a girl, and will go with a girl." As he said this, a few of the most faithful of his nobles and councillors stood round his bed; and as they strove to comfort him, he stretched out his hand for them to kiss, and regarding them with great affection, closed his eyes, and placidly expired. He died in the thirty-fifth year of his age, and the twenty-ninth of his reign.

Somewhat more than two centuries and a half had elapsed since the death of Alexander the Third had left the country under circumstances of calamity and danger strikingly similar to those in which it now found itself in losing James the Fifth. Alexander had been bereft of all his sons, and the crown descended to an only grand-daughter, the Maiden of Norway. James had been visited by a like bereavement. His sons, Arthur and James, had been cut off, and his only daughter, Mary, an infant eight days old, was now queen. On the death of Alexander, the kingdom saw itself exposed to the ambitious designs of Edward the First, who immediately conceived the project of marrying the queen of Scotland to his eldest son. On the death of James, Henry the Eighth, a monarch far inferior in talent to Edward, but equally ambitious, and, where the rights of others were concerned, still more unscrupulous, at once embraced the design of marrying his son the prince of Wales to the infant Mary. Edward, when disappointed of his first object by the death of the infant queen, resorted to intrigue and force to accomplish his purpose; and Henry having been baffled in his ambition, not indeed by the death, but by the betrothment of Mary to the dauphin, resorted to the same weapons to effect his designs. One point of the parallel, and that the most mortifying of all, remains. In the days of Edward, Scotland was basely deserted by her leading nobility, and owed her liberty to the inherent love of freedom and the persevering courage of her people. It was the same under Henry the Eighth and Edward the Sixth. The lapse of two centuries and a half found the great majority of the Scottish nobles as selfish, wavering, and unprincipled as their ancestors in the days of Edward,—supported by the money of England, ready to sacrifice the independence of their country to their individual ambition; and if Scotland preserved her liberty as a separate kingdom, which, by the blessing of God, she did, the agents selected for her deliverance were the great body of her people, and the numerous and influential classes of the clergy. From these general remarks let us return to our historical sketch.

The rout at the Solway Moss, followed, as we have seen it, by the death of the king, gave an alarming advantage to Henry the Eighth. The earl of Angus, Sir George Douglas, and the numerous supporters of this house, still powerful though in banishment, had been long devoted to his interests, in the support of which they saw the only sure hope of their own restoration. To these were added the prisoners of highest rank who were taken in the late disgraceful flight. To them the English monarch now proposed an alternative, trying indeed, but in the choice of which no citizen of a free country ought to have hesitated. On the one hand, they were threatened with imprisonment in the Tower, to which they had been conducted immediately after their being taken. On the other, they were promised freedom, and a return to their native country, but coupled with extraordinary conditions. A bond was drawn up which they were required to sign. By it they acknowledged Henry as lord superior of the kingdom of Scotland; they promised to exert their influence to procure for him the government of the kingdom, and the

Scotland. resignation into his hands of all its fortresses ; they engaged to have their infant queen delivered to his keeping ; and they solemnly stipulated, that if the parliament of Scotland resisted such demands, they would employ their whole feudal strength to co-operate with England in completing the conquest of the country. To this engagement they were required to swear fidelity ; and if they failed in accomplishing the wishes of the king, the penalty was to be their immediate return to their prisons in England. It must have been apparent to the Scottish prisoners that such an engagement virtually annihilated the existence of their country as a separate kingdom ; and yet it is mortifying to add that it was embraced by the earls of Glencairn and Cassillis, with the lords Maxwell, Somerville, and Oliphant. These were among the chief prisoners taken in the rout of Solway Moss ; the rest were of inferior rank, and remained in captivity, while Angus, Sir George Douglas, and the strength of their house, cordially co-operated with Henry.¹

A.D 1542. It was the policy of these lords on their return to Scotland, to conceal the full extent of their engagements, and to proceed with great caution. On their arrival they found the country divided into two factions. On the one side, was cardinal Beaton the chancellor, supported by the queen-mother Mary of Guise, the whole body of the clergy, the Roman Catholic nobility, and the interest of France. On the other stood the earl of Arran, nearest heir to the crown, a weak and indolent man, who leaned to the reformed opinions ; all the nobles who had forsaken the ancient faith, the adherents of the house of Douglas, and many who, ignorant of the unjust and degrading demands of Henry, considered a marriage with England, under due safeguards, as a wise and politic step. As to the great body of the people, by which we must chiefly understand the middle and commercial classes, their feelings, as far as they can be detected, were somewhat discordant. Many favoured the reformation, and from hostility to the cardinal, gave a virtual support to Henry the Eighth and the English faction ; but their feeling of national independence was so strong, that on the slightest assumption of superiority, it was ready to exhibit itself in determined hostility.

Arrival of the Douglases and the Solway prisoners. Into the details of the struggles between these opposite factions, it belongs not to our plan to enter. We must touch only the great leading events ; but these, even in their most general form, are full of interest. On the death of the king, Beaton produced a will which appointed him chief governor of the realm, and guardian to the infant queen ; but the paper was thrown aside as a forged instrument ; Arran, the nearest heir to the crown, was chosen governor ; and the cardinal having contented himself with securing the interest and support of France, prepared for a determined struggle with his opponents. At this moment, the Douglasses and the Solway prisoners arrived, of which party Sir George Douglas, brother to Angus, and father of the celebrated regent Morton, was the leader. Their first act was bold and successful. Beaton was arraigned of a treasonable correspondence with France, and hurried to prison ; a parliament was summoned for the discussion of the proposed alliance with England ; and as the governor, Arran, appeared to be completely under English influence, it was confidently expected that Henry's schemes of ambition were not far from their accomplishment. But they were defeated by his own violent and intolerant conduct. He insisted on having the cardinal delivered up to be imprisoned in England ; he upbraided the Douglasses for their delay to surrender the fortresses of the kingdom ; and instead of being contented with the proceedings of the parliament, which agreed to the marriage between the Scottish queen and his son, he expressed the most violent resentment, because the estates

Imprisonment of Cardinal Beaton.

insisted that their country should preserve its liberties as a separate and independent kingdom.

Amidst these collisions the secret treachery of the Douglasses and the Solway lords began to transpire. Beaton nearly about the same time recovered his liberty, and after an ineffectual attempt to secure a matrimonial alliance with England on just and equal grounds, he placed himself and the great party of which he became the leader in determined hostility to Henry. A last effort, however, was made, and a Scottish embassy sought the English court. In a personal interview, the ambassadors explained to the king the conditions on which the country would agree to the marriage. To their astonishment, the monarch, overcome by passion, proclaimed himself lord paramount of Scotland, and insisted that the government of that kingdom, and the custody of its infant sovereign, belonged of right to him. This disclosure, which was made in a moment of passion, and against the earnest entreaties of the English faction, produced an instantaneous effect. It was received in Scotland, as had been predicted, with a universal burst of indignation. It gave the cardinal and the French party an immediate ascendancy ; the governor, Arran, and his friends joined their ranks ; and the people became so exasperated, that Sadler, the English ambassador, could not safely shew himself in the capital.

To counteract all these effects, Sir George Douglas exerted himself with indefatigable activity. Henry was prevailed upon to renounce the most obnoxious part of his demands, Arran, with his characteristic caprice, deserted his new friends ; and in a convention of the nobles, which was not attended by the opposite faction, the treaties of marriage and pacification with England were finally arranged. Yet although, as far as it was promulgated to the people, the negotiation now concluded, preserved entire the rights and liberties of Scotland, a paper has lately been discovered, drawn up at the same time, and entitled a *secret De-vice*, in which the earls of Angus and Glencairn, with lord Maxwell, Sir George Douglas, and the rest of their party, once more tied themselves to the service of the English king, and promised that, if he did not accomplish the full extent of his designs, he should at least have the dominion on this side the Forth.²

To fulfil this treaty, however, was found no easy matter. Treachery It was averred by the opposite faction, that it had been of the earl carried through by private influence, unsanctioned by the highest nobles, unauthorized by any parliament, contrary to the wishes of the people ; and at this very crisis the cardinal obtained possession of the person of the infant queen, who had hitherto been strictly guarded by the governor and the Hamiltons. To balance this success, Arran, whose character had hitherto been only weak, became alarmed at the success of the cardinal ; and, flattered by a proposal of the English king to make him sovereign of Scotland beyond the Forth, declared his readiness to co-operate with an English army for the entire subjugation of the country. In the mean time, he held a convention of the nobles in the abbey church of Holyrood, and in his character of governor of the realm, ratified the marriage treaty with England, unmindful of the protestations of Beaton and his party, that they were no parties to such a transaction, and would not hold themselves bound by a decision contrary to the opinion of the majority of the nobles and the wishes of the people.

Henry the Eighth, enraged by this opposition, acted with his wonted impetuosity and want of principle. He intrigued against the life and liberty of the cardinal, but his plots to get possession of the prelate were unsuccessful ; he seized the ships of the Scottish merchants which were in English ports, a measure which was deeply resented ; and he assumed that tone of haughty defiance, which, when united to his

Scotland. hostile preparations, made it apparent that war could not be long averted. France now offered her assistance to her ancient ally. The earl of Arran, ever wavering and irresolute, once more threw his whole influence into Beaton's hands; and this minister, availing himself of an accession of strength, proceeded with a vigorous hand to suppress heresy, and to inculcate determined resistance to England.

Henry encourages an attempt to assassinate Beaton. Invasion by Henry. Henry, who was thoroughly unprincipled, and cared not what means he used to rid himself of his opponents, attempted to remove the cardinal, by hiring Brunston, Grange, Rothies, and some of the opposite faction, to seize or assassinate him; but he once more failed in this nefarious project, and, foiled and irritated, let loose his vengeance in the shape of a naval invasion. An English fleet of a hundred sail, under lord Lisle, high admiral, appeared suddenly in the Forth, and disembarked a force which plundered Leith, sacked Edinburgh, which had been deserted by its inhabitants, ravaged the adjoining country with merciless cruelty, and left upon land a considerable force, which, in its retreat, was as remorseless in its devastations as the fleet had been in its attack. Such was Henry's mode of wooing, of which it was well observed by lord Herbert, that he did too much for a suitor, and too little for a conqueror.

It might have been expected that the rival leaders and factions in the state, all of whom had suffered by this invasion, would have had their eyes opened to the necessity of saving the country, by uniting their strength; but in vain the cardinal strained every effort to effect so desirable a result. Mutual jealousies, feudal quarrels, renewed intrigues with England, private bonds or covenants among themselves, all co-operated to destroy any cordial union; and the earls of Lennox and Glencairn, two of the most powerful of the Scottish barons, seized this opportunity to sell themselves to Henry, and to conduct a hostile expedition into the heart of Scotland.

Battle of Ancrum Muir. A.D. 1544. It was at this moment, when all was gloom and despondency, that the earl of Angus, who, with his brother, had been lately restored to his estates, and absolved in Parliament from the sentence of treason, encountered and totally defeated Sir Ralph Evre and Sir Brian Layton at Ancrum Muir. These English leaders had procured from Henry a grant of all they could conquer in Teviotdale and the Merse, where Angus's estates chiefly lay; and penetrating at the head of five thousand men to Melrose, they not only ravaged that district, but plundered the abbey, and wantonly defaced the tombs of the house of Douglas; an insult which Angus revenged in the most signal manner, by attacking the English in their retreat, dispersing their force, with the slaughter of eight hundred men, leaving Evre and Layton dead on the field, and making a capture of one thousand prisoners.

This victory, although resulting not from patriotic principle, but personal revenge, had a good effect in restoring confidence to the people; and it was followed up by the resolution of Francis the First to equip a fleet for the invasion of England, and to assist Scotland by an auxiliary force. Beaton, encouraged by this expected aid, having concentrated his party, prevailed upon the majority of the nobles, in a convention held in the capital, to refuse every advance of the English monarch, and to declare the treaty of peace and marriage at an end; while Henry, enraged to the utmost pitch by this success, eagerly encouraged a second plot of the earls of Cassillis, Angus, and Glencairn, for the murder of the cardinal. The king, however, enjoined Sir Ralph Sadler to propose the assassination, as coming from himself, and the conspirators

at this moment would not act without Henry's direct approval.¹

In the midst of these dark plots, a French fleet arrived in Scotland with three thousand men. This led to decisive measures. A Scottish army was assembled; but torn as usual by internal dissensions, and betrayed by the Douglasses, who held a principal command, its operations were insignificant, and its retreat almost immediate. This was followed by a cruel invasion of the English, in which the earl of Hertford, at the head of an army, whose numbers rendered opposition fruitless, invaded Scotland, and after a desolating progress, sent word to his master, that for three hundred years there had not been such ravages committed. Seven monasteries and religious houses, sixteen castles and towns, five market towns, two hundred and forty-three villages, thirteen mills and three hospitals, were burned down during this atrocious expedition; and there still exists a characteristic letter, in which Henry, on receiving some French deserters into his service, enjoins them to show their attachment by some notable exploit, such as the "trapping or slaying the cardinal." He, at the same time, engaged the earl of Lennox, and Donald, lord of the Isles, to attack Scotland on the west coasts; and having heard that Beaton, his able and indefatigable enemy, meditated a visit to France for the purpose of subsidising a large auxiliary force for the continuance of the war, he determined to make a last effort to cut him off, and with this view, resumed with the laird of Brunston the plot for his assassination.

Into the details of this remarkable conspiracy, and the various parties whom Henry contrived to bring together for the execution of his sanguinary purpose, we cannot here enter.² Fanaticism of the sternest kind, which had been worked up into action by the cardinal's cruel execution of George Wishart, commonly called the martyr, united itself to more mercenary motives with some of the conspirators, and with others, to the desire of private revenge; and on the morning of the 28th of May, a band of desperate men, who are now known to have been in the pay of England, and some of whom had been on former occasions urged by the English king to the commission of the murder, broke into the cardinal's apartments in the castle of St. Andrews, beat down the barricades with which the miserable man had attempted to defend the door, and putting him instantly to death, hung out his naked and mangled body over the window of his bed-chamber, in savage and brutal triumph. They then seized the castle, dismissed unharmed the household servants of the cardinal, sent off a messenger to the English court to inform Henry of their success; and being soon afterwards joined by John Knox, and a considerable band of his friends, who considered the death of Beaton as favourable to the reformation, they determined to defend the castle for Henry against any force which might be brought against them.

These confident anticipations were, for a time, overthrown by the death of Henry the Eighth, an event soon followed by that of his rival Francis the First; but the accession of Edward the Sixth in England, and that of Henry the Second in France, did not materially alter the policy of either kingdom towards Scotland. In England, the protector Somerset, who was placed at the head of the government during the minority of his royal nephew, considered himself bound to enforce the observation of the marriage treaty between Edward and the young queen of Scots; while in France, Henry the Second, devoted to the cause of the Catholic church, and directed in his affairs by the Guises, foresaw at once the necessity of an intimate union with Mary of

¹ Tytler's History of Scotland, vol. v. pp. 388, 389.

² The whole of the plot, as it is to be traced in authentic letters in the State Paper-Office, will be found detailed in Tytler's History of Scotland, vol. v. p. 387—391, and in an Appendix to that volume, entitled, "Historical Remarks on the Assassination of Cardinal Beaton."

Scotland. Guise the queen-dowager, and the governor Arran; his policy being to arrest the spread of the reformed opinions, and to weaken England in the quarter to which Somerset looked for an easy triumph.

Arrival of
a French
fleet in
Scotland.

For nine years after the assassination of Beaton, the earl of Arran continued at the head of the government; and during that period some events took place which drew after them important effects. The warlike preparations of Somerset induced the French government to anticipate his motions; and a French fleet of sixteen armed galleons having entered the Frith, bombarded and carried the castle of St. Andrews, in which the conspirators against Beaton, and Knox the Scottish reformer, had deemed themselves secure.

Knox called to the ministry.
A.D. 1546.

It was when shut up in St. Andrews, that this extraordinary man first assumed the office of a minister of the reformed religion; but having capitulated with the rest, he was embarked with his associates for France, and on his arrival there, kept a prisoner in chains on board the galleys. He remained on the continent till 1550, when he returned not to Scotland, but to England, and became one of the chaplains to Edward the Sixth.

Somerset invades Scotland.
Battle of Pinkey
A.D. 1547.

Immediately after the siege of St. Andrews, the protector Somerset invaded Scotland at the head of an army of fourteen thousand strong, and supported by a fleet of thirty-four ships of war. He was met by Arran, the governor, at Musselburgh, or Pinkey-cleugh, within about six miles distance from the capital, where an army considerably more than double the number of the English had encamped in so strong a position on the banks of the Esk, that with proper military skill on their part, any attempt to dislodge them might have brought ruin on their assailants. The inexperience and folly of Arran, the governor, threw away this advantage. He mistook a movement of Somerset, in which the English leader meant to possess himself of an adjoining height, for an intention to communicate with his fleet and re-embark his army; and contrary to the remonstrances of his best officers, he gave orders for the whole army to strike their tents and cross the river on which he had encamped. The order was at first resisted, at last unwillingly and imperfectly obeyed; and in the midst of the confusion which ensued, the English attacked the Scottish divisions in detail, and after a sanguinary conflict, gained a complete victory. Fourteen thousand were slain in the battle and in the chase, while the English loss was comparatively trifling.

Since the fatal day of Floddon, Scotland had sustained no defeat in the least degree approaching to this at Pinkey, and had it been followed up by the Protector, the consequences must have been of the most serious kind, perhaps fatal to the liberty of the country. But happily Somerset, at the very moment of his victory, received accounts of a conspiracy which his enemies at the English court had organized against him; and impatient to confront them in person, his measures were hurried, confused, and ill-digested. After a brief stay in the capital, he commenced his retreat through Teviotdale, and the fleet at the same time weighed anchor and returned to England.

Mary sent to France, and betrothed to the Dauphin.

The consequences of the defeat at Pinkey, and the effects of a subsequent and cruel inroad into Annandale by Lord Wharton and the earl of Lennox, were to exasperate the feelings of national antipathy, and to throw the governor and the queen-mother more decidedly into the arms of France. A convention was held at Stirling, in which it was determined to request the immediate assistance of a French force, and to send Mary, the young queen of Scots, to be educated at the court of Henry the Second. Soon afterwards, the Sieur Montalembert, commonly called Monsieur d'Esse, one of the ablest officers in the service of that country, arrived in Scotland with six thousand men. In a parliament held at Haddington, the marriage of the French dauphin to the queen of Scots was finally determined; and the infant Mary,

then in her sixth year, took her voyage to France, accompanied by lords Erskine and Livingston, her governors, and arrived in safety at the court of St. Germain, in August 1548.

Scotland.
Mary
A.D. 1548.

It belongs not to an historical sketch of this kind, to enter into the details of that sanguinary and obstinate war which now took place between England and the united strength of France and Scotland. The slaughter at Pinkey, the burning of their sea-ports and shipping, and the pitiless severity with which the repeated invasions of their country were accompanied, had at length animated the Scots with a common feeling of revenge, which gave to the contest a character of peculiar ferocity, and manifested itself in shocking excesses. Happily the struggle did not continue long. The peace of Boulogne, between France and England, led, in 1550, to a cessation of hostilities in Scotland, where for some time before, the tide of success had run in favour of the governor and his foreign auxiliaries; and thus, after a war which had lasted for seven years, dating it from the year 1543, when Henry the Eighth determined to enforce the observation of the treaty, the English saw themselves obliged to abandon the extravagant project of compelling the Scots into a matrimonial alliance.

This war, for the accomplishment of the marriage, was not long afterwards followed by the still more important and eventful struggle for the establishment of the reformation, the history of which may properly be divided into the war of opinion, which extended from the arrival of Knox in Scotland in 1555, to the attack upon Perth in 1559; and the actual war between the Congregation and their opponents, which was comparatively of short duration, and concluded in the treaty of Edinburgh and the triumph of the party of the Congregation, in 1561. How difficult is it, in the narrow compass allowed us for this picture, to do justice even to its prominent outlines? The queen-dowager, Mary of Guise, a woman, by the confession of her enemies, of good judgment, and sincere and upright principles, succeeded in procuring the retirement of Arran and her own nomination to the regency, (April 1554). She was enabled to accomplish this chiefly by the influence of France, then high in Scotland; but she was assisted also by the leaders of the protestant party, whom she courted and attached to her interest. Her possession of the supreme power was soon followed by the death of Edward the Sixth and the accession of Mary, a princess, as is well known, sincerely devoted to the ancient faith; but these changes were not accompanied by any important political events. The queen-dowager, indeed, when she saw England and Spain engaged in Italy in a struggle with France and the pope, deemed it her duty to support her country and attack England; but although the Scottish barons assembled an army, it was only to act on the defensive; they refused to cross the border, and the Regent, hitherto on the most amicable terms with the nobles, dismissed them with undissembled resentment.

To make up for this disappointment, the marriage between the young queen of Scots and the dauphin was concluded with much solemnity at Notre Dame; and in a parliament held at Edinburgh, it was agreed that the youthful husband should bear the title of king of Scotland during the continuance of the marriage, that all letters in Scotland should run in the joint names of Francis and Mary, and that the arms of both kingdoms should be quartered in the great seal and the current coin of the realm. These transactions had not been long concluded, when Mary of England, broken-hearted by the loss of Calais and the neglect of Philip, sunk into the grave; and Elizabeth's accession to the throne was hailed with universal delight by the protestant party in Europe.

When the English queen placed herself at the head of the reformation, this great moral revolution had made no inconsiderable progress in Scotland. The return of Knox to his native country in 1555, and the influence which his

This bond was little less than an open declaration of war against the established religion; and lest it should be misunderstood, the lords of the Congregation at the same time passed a resolution, declaring, that in all parishes the common prayer, by which was meant the service book of Edward the Sixth, should be read in the churches by the curates, if qualified to perform this service, if not, by others in the parish who were qualified. It was resolved at the same time, that doctrine, preaching, and the interpretation of Scripture should be used privately, until it pleased God to move the prince to grant public preaching by faithful ministers.

Burning of
Walter
Mill.
A.D. 1558. The Roman Catholic clergy received such a denunciation of the national faith with alarm and indignation; and resorting once more to those weapons which had already so deeply injured their cause, they deemed it expedient to hold up an example which should strike terror into the new converts. Walter Mill, a priest who had embraced the reformation, was seized, tried, delivered over to the secular arm and burned at St. Andrews. The people, however, only execrated the cruelty of which he was the victim, and his last words were never forgotten. "I am now fourscore and two years old, and could not have lived long by the course of nature; but a hundred better shall rise out of the ashes of my bones, and I trust in God I am the last who shall suffer death in Scotland for this cause." A pathetic declaration, and happily prophetic.

Remonstrance of
the Congregation.
A.D. 1558. Against this cruel execution, the lords of the Congregation, Glencarn, Argyll, Morton, Erskine of Dun, and others, presented a remonstrance to the queen-dowager. It was impossible, they said, that her Grace could be ignorant of the controversy which had arisen between them and the popish clergy, concerning the true religion and the right worshiping of God. They denounced the power which was claimed by these priests of dictating their creed under the penalty of fire and faggot, and declared, that although hitherto they had remained quiescent under such abuses, they now were persuaded, that they, "as part of that power which God had established in the land," were bound to defend their persecuted brethren. They proceeded still more boldly to state, that a reformation of abuses was necessary, not only in religion, but in the temporal government of the state; and after claiming for themselves the free right of assembling in public or private, hearing common prayers, and having the sacrament of the Lord's Supper administered in the vulgar tongue, they concluded by declaring that they were willing that the controversy between themselves and the Catholic priesthood should be determined by a reference to the New Testament, the writings of the fathers, and the laws of the emperor Justinian. This declaration was soon after followed by a supplication to parliament, in which they requested that all statutes by which churchmen were empowered to proceed against heretics, should be suspended until the controversies in religion were determined by a general council of the church.

Proceedings of the
queen-dowager. This petition was received by the queen-regent with concealed dissatisfaction, by the great body of the Roman Catholic clergy with undisguised scorn and reprobation. It suited however the regent at this moment to dissemble. She required the aid of the protestant lords to carry her favourite measures in this parliament, the obtaining the crown-

matrimonial and the title of king of Scots for the dauphin; and intreating the lords of the Congregation to withdraw their petition and articles for a season, she promised them her protection, and a favourable consideration of their demands. To this they agreed, but under a protestation which was publicly read in parliament. It proved by the manner in which it was worded that they knew their own strength; and, in the event of a refusal, were prepared to enforce their demand for liberty of conscience and a thorough reformation of the church.

It was at this crisis, when the lords of the Congregation had taken their stand on the ground which they never afterwards deserted, and when the queen-regent, having obtained her wishes, considered herself independent of their support, that Elizabeth succeeded to the throne, and Knox, who soon after his first return had left Scotland, again arrived in his native country. Both events produced the most important effects. It was one of the great principles of Elizabeth's policy to increase her own security by weakening her neighbours; to accomplish which, she invariably fomented a secret faction which opposed itself to the existing government. We have already seen how lightly the feudal nobility of Scotland were accustomed to regard the power of the crown or the laws of the realm, if they interfered in any prominent manner with their personal freedom or privileges; and the history of the country, from the rebellion in the reign of James the Third, to the moment when they so recently refused to lead their forces against England, had exhibited little else than the total destruction of any balance between the fierce unbridled license of the aristocracy, and the decreasing influence of the crown and the laws.

Of those nobles who had been ready, without any feelings of shame, to renounce their allegiance to their country, and to be bought over by England, many had embraced the principles of the reformation. To men so long accustomed to make their personal interest the measure of their duty, and to think and act as they pleased, a revolution which contended for liberty of conscience and the license of private judgment, must have warmly recommended itself; and when they considered the history of the English reformation, and the appropriation of the church lands by Henry and Edward, they could not, we may believe, be totally dead to the lesson. The church of Rome in Scotland was comparatively as rich as her sister had been across the border; and if the reformation was to be as complete in their own country as in England, it was not difficult for these shrewd barons to persuade themselves that they might imitate, perhaps improve the example.

Over an aristocracy of such a character, Elizabeth and her ministers at once perceived how easy it would be to acquire an influence. Her policy at home was to avoid war, and to enforce in every department of the state the most rigid economy. Her policy abroad, as already observed, was to give her neighbours full employment within their own realm, by secretly encouraging every faction which rose against the government. From the first moment of her accession, therefore, she favoured the leaders of the Congregation, directed their measures, supported them with money, and received from them in return a respect and deference superior to that which they paid to their own sovereign.

But if the effects of the accession of Elizabeth upon the body of the Scottish nobles, were important in reference to the reformation, the consequences of Knox's re-appearance were not less momentous upon the character of the people. Hitherto the healthy patriotic feeling, the resolution to defend their independence as a separate kingdom from foreign domination and attack, had existed almost exclusively in the middle and lower orders, the commercial classes, and the labourers of the soil. But among these, the principles of the reformation had taken a deep root. They had adopted

them, not like many of the nobles, from interest, but from conviction; and upon their minds the popular eloquence of Knox, his fiery zeal, his denunciations of superstition, his sarcastic attacks upon the ignorance and the vices of his opponents, produced a powerful impression. Till this period they had been wont to regard France as their ancient ally, and England as their ancient enemy. But France was now held forth to them, in the discourses of their favourite preacher, as their bitterest foe, because the enemy of their soul's health; while England was the land of gospel light, and its queen the princess to whom, as the bulwark of the truth, they ought to look with affection and admiration.

Such were the feelings of the Scottish nobles, and the great body of the people, with reference to the momentous struggle between the reformation and the Roman Catholic faith, which was now about to convulse the country. Had the queen-dowager continued to act with the same judgment and caution which had distinguished the commencement of her government, it is possible that the struggle might have been for a time averted; but at this moment the powerful princes of the house of Guise deemed it expedient to join the league which had been concluded between the pope, the king of Spain, and the emperor, for the destruction of the protestants, and the re-establishment of the catholic faith in Europe. They immediately communicated with their sister, the regent, in Scotland; and such was unfortunately their influence over her mind, that after a feeble resistance she joined the papal coalition.

A.D. 1558.
Collision
between
the Catho-
lics and the
Protest-
ants.

This fatal step was followed, as might have been expected, by an immediate collision between the two parties. In a convention of the clergy which was held at Edinburgh, in March 1559, the lords of the Congregation, in addition to the demands which they had already presented, insisted that bishops should not henceforward be elected without the consent of the gentlemen of the diocese, nor parish priests except by the votes of the parishioners. These proposals were met by the queen with a determined refusal. A proclamation was issued, commanding all persons to resort daily to mass and confession. It was declared that no language but the Latin could be used in public prayers, without violating the most sacred decrees of the church; and the protestant ministers who had acted in defiance of these injunctions, were summoned to appear at Stirling, and there answer to the accusations which should be brought against them.

They accordingly did appear; but it was with Knox at their head, and surrounded by crowds of their devoted followers, who were led by the principal barons of Angus and Mearns. On reaching Perth, however, it was judged expedient to attempt a measure of conciliation; and Erskine of Dun, a gentleman of ancient family, and grave experience, leaving his brethren, proceeded to the court at Stirling, where he was admitted to an interview with the regent. He assured her that their single demand was to be allowed to worship God according to their conscience, and to secure liberty for their preachers. She replied, that if he would prevail on the Congregation to disperse, their preachers should be unmolested, the summons discharged, and their grievances redressed.

Duplicity
and severity
of the
queen-re-
gent.

To this Erskine consented. He communicated the agreement to his brethren; the people were disbanded; and when the reformers looked for toleration and redress, the queen-dowager, with a perfidy which was as base as it was unwise, reiterated the summons, and on their failure to appear, denounced the ministers as rebels. Such conduct inflamed the resentment of the Congregation to the utmost degree; and Knox having seized the moment to deliver a stern and impassioned sermon against idolatry, the people were wrought up to a state of high excitement. Observing a priest about to celebrate mass, after the preacher had retired, they burst in upon the altar, tore down its ornaments, shivered

the shrines and relics, and speedily demolished every monument which seemed to savour of idolatry. From that moment the fate of the Roman Catholic church in Scotland was decided. Having once broken through restraint, and found their own strength, the multitude rushed to the religious houses of the Black and Grey friars, and inflicted on them an equally summary vengeance. They then attacked the charter-house or Carthusian monastery, which experienced a similar fate; and the infection of tumult and destruction spreading throughout the country, many excesses of the same kind were committed in the provincial towns. That Knox or his disciples directly advised such spoliation cannot be proved; that the principles which he laid down, and his stern denunciations of his opponents as idolaters, led to these excesses, is certain.

The effects of such scenes on the queen-dowager, were to rouse her to instant activity, and to array the two parties in determined opposition to each other; for although some of the protestant leaders, disclaiming all intentions of rebellion, disapproved of the late violence, and still acted with the regent, their neutrality was so short-lived that it scarcely demands attention. It had the effect, however, of producing a momentary spirit of conciliation. The protestants presented an address to the queen, to the nobility, and to the Roman Catholic clergy. In the first they professed their loyalty, deprecated her injustice, and demanded liberty of conscience, and the right of hearing their own preachers. In the second they vindicated their conduct to their brethren of the Roman Catholic nobility from the charge of heresy and sedition, while they upbraided those who first espoused and now deserted their cause. The third epistle to the Roman Catholic clergy, whom they broadly stigmatized as the generation of antichrist, was a denunciation of war, composed in that spirit of coarse and abusive railing which unfortunately marks the style of the early reformers. Such accusations were little calculated to produce pacific feelings; but the queen-regent, who had assembled her army, finding it inferior in strength to the Congregation, proposed an armistice, which on certain conditions was accepted. The Congregation having bound themselves to each other in a new covenant, disbanded their forces, and for the second time, as they allege, were overreached by the treachery of the dowager, who, against a solemn stipulation, occupied Perth with a body of French soldiers, expelled the magistrates who favoured the reformation, and garrisoned the town with troops in the pay of France, though in reality Scots.

This unwise and unjustifiable duplicity had the worst effects. The lord James, afterwards the regent Murray, a young man of great talents and ambition, who had hitherto adhered to the regent, though professing reformed opinions, deserted her. Argyll, a powerful and influential nobleman, followed his example; and, faithful to their renewed covenant, the army of the Congregation assembled in strength at St. Andrews. Knox in the mean time, whose voice, Sadler, the English ambassador, compares in his letters to the sound of a thousand trumpets, set out on a preaching tour through the country. Directing his powerful and popular eloquence against the evils of superstition, and the misery of the thralldom which, by means of foreign mercenaries, the house of Guise were attempting to fix upon their country, he so powerfully excited the people, that they determined to take the reformation into their own hands, and levelled with the ground the monasteries of the Franciscan and Dominican orders. It was in vain that the regent exerted herself to check these popular outrages. The phrensy gained strength; the nobles and leaders of the Congregation felt proportionally encouraged, and advancing with their forces upon Perth, they opened a cannonade, and in a short time made themselves masters of the town. Stimulated to a high pitch of excitement by such success, the

Scotland. multitude, contrary to the entreaties of Knox, attacked and destroyed the abbey church and palace of Scone; after which, a portion of the army of the Congregation, under the lord James and Argyll, made a rapid march upon Stirling, which they occupied, hastened afterwards to Linlithgow, and having in both towns pulled down the altars, destroyed the shrines, and, as they said, purged the places of idolatry, they compelled the regent to make a rapid retreat to Dunbar, and entered the capital in triumph, in June 1559.

The queen-regent calls for French assistance. This last success, while it gave the highest courage to the party of the reformation, convinced the queen-regent that every hope to avoid a civil war must be abandoned, and that the crisis called for her most determined exertions. She instantly communicated her dangerous situation to France, and received in return a large reinforcement of French troops, whose discipline, skill, and equipment, being superior to the common feudal militia which the Congregation brought into the field, at once gave her a superiority. The reformers, on the other hand, threw themselves upon the protection of England; and Elizabeth, although she scrupled to send them either money or troops, encouraged them with general promises of approval, and, in case of extreme danger, with some hopes of support. In addition to this, her minister Cecil hinted in his letters the expediency of using their present power to "strip the Romish church of its pomp and wealth," and, as he termed it, "to apply good things to good uses;" while the terms in which the Congregation replied, seem to point to a more secret communication, in which this unscrupulous politician had advised the deposition of the regent, and a change of the government. It is certain that the necessity of such a measure had been for some time contemplated by the Congregation, but it was to be resorted to as the last extremity. In a letter from Kirkcaldy of Grange, one of their principal leaders, addressed to Sir Henry Percy, (1st of July 1559), and explanatory of their intentions, he declared that if the regent would consent to a reformation conformable to the pure word of God, cleanse the popish churches of all monuments of idolatry, suffer the book of common prayer published by Edward the Sixth to be read, and send away the French troops, they were ready to obey and serve her, and to annex the whole revenues of the abbeys to the crown.

Deposition of the queen-regent. For the queen-dowager to have agreed to this would have been equivalent to the giving up of the whole question, and would have been to establish protestantism on the ruins of what she esteemed the true church. She accordingly met the demands of the Congregation by a peremptory denial. In return they withdrew from her their allegiance, and in the name of their sovereign, whose authority they unscrupulously assumed, suspended her from the high office which she had abused.

The war now broke out with a violence proportioned to the exasperated feelings of either faction. The Congregation, at first intimidated by the superiority in the discipline of the French troops, began to dread a calamitous result; but they soon saw themselves strengthened by the arrival of an English fleet, while a land force under the duke of Norfolk advanced to Berwick, and after a negotiation with the reformed leaders, pushed forward into Scotland, and was joined at Preston by the army of the reformers.

The war is of brief duration. Treaty of Peace at Edinburgh, A.D. 1560. It belongs not to this sketch to enter into details of hostilities, and happily for both countries the war was of brief duration. The queen-dowager, sinking under a broken constitution, died at Edinburgh, on the 10th of June 1560. The Congregation, disheartened by some reverses, and weakened by disunion among their principal leaders, felt no inclination to prolong the struggle; and Elizabeth having offered her services as a mediatrix between the two parties, a meeting of the English, French, and Scottish commissioners

took place at Edinburgh, by whom a treaty of peace was concluded, having for its basis the withdrawal of the French troops from Scotland, and a recognition of the validity of the treaty of Berwick between Elizabeth and the party of the congregation. Into this last proviso the French commissioners sent over by the young queen of Scots and her husband the dauphin, were entrapped by the diplomatic skill of Sir William Cecil, one of the English commissioners, contrary to their express instructions; and its validity was never admitted by the Scottish queen; but in the mean time it greatly strengthened the hands of the Congregation. At the same moment the leaders of this party presented to the commissioners certain "articles" concerning religion; but Elizabeth had directed Cecil and Woolton to decline all discussion upon the subject; and the reformers, who looked to the convention of Estates for the settlement of the question, did not press the point.

A parliament accordingly assembled at Edinburgh, on the 10th of July 1560. The lesser barons who had for some time suffered their rights of sitting in the convention of estates to fall into disuse, were mostly attached to the doctrines of the reformers, and looked with deep interest to the debates which were about to take place on the subject of religion. They accordingly met, claimed their right, and after some opposition, were allowed to take their place. This threw a preponderating weight into the party of the Congregation; and the "Confession of Faith," together with a "Book of Confession Discipline," which embodied the great principles of a reformed church, and protested against the errors, abuses, and superstitions of the Roman Catholic faith, was submitted to Parliament. The Confession of Faith passed with little opposition. This remarkable paper, or rather treatise, professes to be a summary of Christian doctrine founded on the word of God; and although drawn up by Knox and his brethren in a very short space, embodied the result of much previous study and consultation. It is worthy of observation, that at this early period, the church of Scotland, in explaining the articles of its faith, approaches indefinitely near to the Apostles' creed, and the articles of Edward the Sixth; and that where it differs, it leans more to the side of catholicism than ultra-protestantism.

Three acts followed the adoption of this Confession of Faith. The first abolished for ever in Scotland, the power and jurisdiction of the Pope; the second repealed all former statutes passed in favour of the Catholic church; the third inflicted the highest penalties upon any who thenceforward should dare to say or to hear mass.

All this met with little opposition; but the Book of Discipline, by which the future government of the church was to be determined, gave rise to the keenest debates. "Some of the nobles and barons at once refused to sign it; others did sign, but eluded its injunctions; others mocked at its provisions, and called them devout imaginations."¹ The cause of this is attributed by Knox to its interfering with the privileges and property of many powerful barons who had already "gripped the possessions of the church." It also discouraged other expectants, "who thought they would not lack their part of Christ's coat."² The first class, according to the same authority, had no remorse of conscience, nor intended to restore any thing of that which they had long stolen or reft. The second were no doubt afraid, that if the ministers were first provided for, little or nothing would be left for them.

In considering its provisions it is material to notice, that it committed the election of ministers solely to the people, using, however, the precaution that the minister so chosen before he was admitted to the holy office, should be examined and approved of by the ministers and elders, upon all points of controversy between the church of Rome and the

¹ Tytler's History of Scotland, vol. vi. p. 219.

² Knox's History, p. 276.

Scotland. Congregation; after which he was to be considered an ordained minister, without any further solemnity, it being observed that although the apostles used the imposition of hands, it was intended to impart, and did impart miraculous powers, and "the miracle having ceased, the using the ceremony was judged henceforth unnecessary." The country was divided by it into ten dioceses, over which ten ministers, named Superintendents, were appointed, whose duty it was to be ambulatory preachers, and to inquire, in the course of their progress, into the lives of the clergy, the provision for the poor, and the proper instruction of youth. It is in this last clause that we meet with the first proposal of that admirable institution of parish schools, to which Scotland has since owed so much of her prosperity. Having thus established their reformation, the Parliament appointed an interim provisional government, confirmed the treaty of Berwick which had been entered into between Elizabeth and the Congregation, and proposed that as a basis of perpetual amity between England and Scotland, there should be a marriage between queen Elizabeth and the earl of Arran, heir apparent to the crown. In conclusion, they dispatched Sir James Sandilands of Calder to carry an account of their proceedings to their sovereigns in France, while Sir William Maitland of Lethington, with the earls of Morton and Glencairn, were sent on a similar mission to Elizabeth.

Mary's feelings towards the Congregation. She refuses to ratify the treaty of Edinburgh. A.D. 1560. It was not to be expected that their youthful sovereign, educated in the bosom of the Roman Catholic church, and accustomed to look for direction and guidance to the advice of her uncles the Guises, could possibly ratify the extraordinary proceedings of this parliament. It had, by a few sweeping acts, abolished the national faith, confirmed the treaty which a faction of her subjects whom she had all along treated as rebels, had entered into with England; and by sending an embassy to Elizabeth, composed of men of higher rank and greater influence than Sandilands, who was deputed to wait upon their sovereign, it was intimated pretty significantly, that the Congregation were determined to treat the English princess with equal if not superior deference to that with which they regarded their own queen. She accordingly received the Scottish envoy with coldness, and peremptorily refused to ratify the treaty of Edinburgh.

Death of Francis the Second. At this moment Mary had the misfortune to lose her husband, Francis the Second, the young king of France; an event which made it necessary for her to return to her own kingdom, and at once threw her from a condition of much contentment and prosperity into circumstances of extraordinary trial and embarrassment. She had been educated in the most brilliant and accomplished, but, it must be added, one of the most profligate courts in Europe. From her infancy, as queen of Scotland, and presumptive queen of France, she had been flattered and caressed; and as she was extremely beautiful, possessed of amiable manners, highly accomplished, generous, and kind-hearted, she had received from every class of her French subjects the unaffected homage of their admiration and regard. All was now to be changed; and on turning her eyes from France to her own country a melancholy contrast soon presented itself.

Parliament at Edinburgh. Character of the Lord James. As soon as the king's death was known in Scotland, a parliament assembled at Edinburgh, of which the proceedings appear to have been overruled by the Congregation. It was resolved to invite their sovereign to return to her kingdom, and for this purpose to send the lord James to France, while the Roman Catholic party dispatched Lesley, afterwards the celebrated bishop of Ross, on the same errand. The lord James, afterwards the regent Murray, was the natural son of James the Fifth by lady Margaret Erskine, who afterwards married the laird of Lochleven. From his earliest years he had exhibited marks of an extraordinary

ambition, and a genius for affairs of state. His apparently blunt and careless manner, disposed men to treat him with confidence, and enabled him, when he was least suspected, to carry on the most deep-laid and ambitious designs. At this moment he was regarded as the leader of the reformed party; and it is a remarkable proof of his talents, that, on his arrival in France, although at first suspected by Mary, he acquired an extraordinary influence over her character.

Scotland. Mary. A.D. 1560. It was the misfortune of the queen of Scots, who was now only eighteen, that she was surrounded by difficulties which would have required to meet them a matured experience, and the most attached and faithful councillors. Elizabeth, who saw her opportunity, and was determined not to lose it, dispatched the earl of Bedford to demand the confirmation of the treaty of Edinburgh; and when this was refused, she exhibited her resentment by declaring that Mary, who had at first intended to pass through England into her own realm, should receive no safeconduct; a circumstance which made her resolve to sail at once from Dieppe to Leith. But Elizabeth was at least an open opponent, and the young queen, aware of her enmity, could secure herself against it. Murray, on the other hand, to whom she too heedlessly gave her confidence, had already visited the English court on his passage to France, communicated his plans to Elizabeth, and received his instructions from Cecil, her prime minister. On his return from Paris he again passed through England, consulted with the English queen on the best methods of detaining Mary in France, and actually carried his double dealing so far as to devise means for intercepting her, should she persist in her determination and set sail. This she at last determined to do at all risks; and having had the good fortune to escape the English cruisers, which were directed to be on the look out, she arrived at Leith, and was received with the utmost enthusiasm by all classes of her subjects, (August 19, 1561).

Difficulties of her situation. These happy indications were of short duration; and when the young queen considered the state of parties in Scotland, the difficulties of her situation appeared complicated and disheartening. She was herself a conscientious Roman Catholic, warmly attached to France and the Guises her uncles. This of itself rendered her an object of suspicion and aversion to Knox, the great leader of the protestant clergy, and to the powerful nobles who had espoused the reformation. She had already peremptorily refused to sanction the proceedings of the Parliament, which had confirmed the treaty of Berwick, abolished the papal supremacy, and substituted the protestant doctrines and worship for the ancient faith. This drew upon her the enmity of England, and the English party in Scotland, led by Murray and Lethington; and as the influence of Knox and the preachers over their congregations was strong and universal, the feelings of the ministers were communicated to the great body of the people, and checked those sentiments of loyalty which manifested themselves upon her arrival. If, from such opponents, Mary turned to the body of her Roman Catholic nobles, among whom the most powerful and influential was the earl of Huntly, she found them animated indeed upon one great subject, by a community of sentiment; but then they, in common with all the nobles, had been so long accustomed to independence, and looked so constantly to the preservation and increase of their own power that, as a party, they were extremely difficult to manage. Lastly, looking to the great body of the Roman Catholic clergy, there was no one who, since the death of Beaton, had possessed that vigour of character and talent for state affairs, which were absolutely necessary in any minister to whom the queen should give her confidence, if we except Lesley, afterwards bishop of Ross.

It was necessary for her, however, to decide upon a line of policy; and after deliberate consideration, the queen determined to make the lord James her chief minister, and to secure the friendship and good offices of Elizabeth. In this

Conduct of Elizabeth and the Lord James.

Difficulties of her situation.

Lord James made chief minister.

Scotland. way she hoped to attach to herself the great body of her people, who were mostly protestants; and as from France, torn at this moment by civil and religious dissensions, she could expect little assistance, she deemed it the more necessary to preserve peace with England. Events of much interest now succeeded each other with a startling rapidity, and the history of Mary, in the brief circle of six years, presented an appalling tragedy, of which we can only give the outline.

Mary's intended marriage A.D. 1561. The first point on which the two queens came into collision was on the delicate subject of marriage. Mary's subjects wished her to marry, and she considered it wise and necessary that she should gratify their wishes. She was in the bloom of youth, extremely beautiful, and of manners so engaging and attractive, that few could see her without sentiments of admiration and regard. She was queen of Scotland, and, after Elizabeth, undoubted heir to the English throne; though this queen, from her morbid jealousy upon the subject of the succession, had never recognised her right. Mary's great object, at this moment, was to marry with her approbation, and to procure a declaration of her right of succession to the throne, failing Elizabeth's issue. She accordingly declared that she would regard her advice upon this subject as that of a mother, and consulted her sister of England with an openness and devotion which, if not perfectly prudent, appears to have been perfectly sincere.

Elizabeth's duplicity. A.D. 1562, 1563. In return for this confidence, the conduct of the queen of England was marked by that insincerity, selfishness, and want of truth which too frequently characterised her policy. She was determined that, if Mary did marry, she should lower herself by the alliance; but she would have been still better pleased could she have so ordered matters that she should not marry at all; and, guided by this ungenerous object, Elizabeth commenced a system of intrigue, the sole object of which was mystification and delay, and in which she enjoyed the satisfaction, not only of deceiving Mary and her councillors, but of setting her own ministers at fault, and rendering it impossible for them to decipher her real intentions. In the course of these negotiations, after objecting to every foreign alliance, the English queen at last proposed her own favourite, Leicester, and held out as a bait to Mary, who justly deemed such an alliance beneath her rank, the promise that the issue, if any, of this marriage should succeed to the English throne. Nothing can be more certain than that she had no such intention; but the farce was so well acted, that not only Mary and the lord James, now earl of Murray, but Randolph, the English ambassador at the Scottish court, were deceived; and when at last the bubble broke, and it was discovered that, from first to last, Elizabeth had been playing her usual dark and double game under the mask of friendship, the indignation of the sufferers was roused, as might have been expected, to the highest pitch.

Mary is incensed, and acts with precipitation. An almost immediate and violent re-action took place. Mary had hitherto confided in Elizabeth, and consulted her upon the marriage. She now trusted her no longer, and determined, without delay, to follow her own inclination. Since her arrival in her dominions, she had favoured the protestants and rather repressed the Roman Catholics. She was now disposed to reverse the system. She had hitherto chosen Murray and Lethington as her chief ministers, had entrusted to the first almost regal power, loaded him with estates and honours, and placed him at the head of her nobility; and it was by Murray and Lethington's advice that she had shaped her policy towards England; but the road they marked out for her had led to insult, mortification, and defeat. Was it possible then, that she could continue to those two men, or to the protestant party, whom they represented, the confidence with which she had regarded them? or rather, was it not natural that, when she discovered their devotedness to Elizabeth, who had deceived and injured her, she should regard them with suspicion and distrust?

Scotland. Under these circumstances, and when agitated by such feelings, Mary saw the lord Darnley, the eldest son of the earl of Lennox, who, with his father, had lately returned to Scotland. This young nobleman could boast of a royal descent, his grandmother being a sister of Henry the Eighth, and he himself, next to Mary, the nearest heir to the English throne. He was now in his twenty-first year, and had not yet discovered that weak intellect and propensity to low vices which betrayed themselves soon after his marriage. It was the misfortune of the Scottish queen that she acted under impulses. She had been deceived by Elizabeth, and she determined to shew her that she could choose for herself. Without giving herself time to study his disposition, and purposely abstaining from any previous communication of her intentions to England, she selected Darnley as her future husband, and dispatched Lethington to Elizabeth, not, as before, to ask her counsel, but to inform her of her resolution.

The consequences of this step were extraordinary. Darnley and his father were strongly suspected of being Roman Catholics. Murray and Lethington saw in this alliance little else than the demolition of their own power; the party of Knox and the kirk anticipated the restoration of the ancient religion; and Elizabeth not only declared herself hostile to the alliance, but bitterly accused the Scottish queen, insisted that Lennox and Darnley were English, not Scottish subjects, and sent them orders to repair instantly to her court. It was hardly to be expected that so ridiculous a command should be obeyed, and the opposition of England only rendered Mary more determined upon the marriage. A convention of her nobility was held at Stirling; it was numerous attended; the queen communicated to them her intention of marrying Darnley; the measure was approved without a dissentient voice; and although Murray, Darnley and the faction with whom he acted, attempted to instigate the people to opposition and rebellion, the endeavour was signally unsuccessful, and the queen carried her wishes into effect. She was married to Darnley in the chapel of Holyrood, on the 29th of July 1565.

Previously to the queen's marriage, Murray, Argyll, Lethington, and the party of the kirk had been encouraged by Murray and Elizabeth to rise against their sovereign; and had they received from the English queen the substantial assistance which she promised, the result might have led to the dethronement of her whom they represented as the oppressor of her nobility, and the bitter enemy of the truth. But their schemes were defeated by the energy and promptitude of the Scottish queen and the timid parsimony of her sister of England. It was in vain that Murray and his brother insurgents reminded Cecil of their desperate situation, and the necessity of speedy assistance both in money and in soldiers. Neither the one nor the other could be wrung from Elizabeth. They were proclaimed traitors, driven from one position to another by the queen of Scots, who herself headed the forces which she led against them, and were at last compelled to fly to England and throw themselves upon the protection of Elizabeth. To their dismay she disowned and repulsed them; upbraided Murray as a traitor to his royal mistress; and, although herself the encourager of their revolt, compelled them publicly to declare that she knew nothing of the matter. They were then dismissed from the queen's presence, and permitted to retire to Carlisle, where the earl of Bedford received secret instructions to supply their wants during their banishment.

While such was the course of events in England, Mary's satisfaction in the triumph over her rebels was grievously diminished by discovering that her husband was weak and profligate, the dupe of every artful companion whom he met, and unworthy of the confidence and affection with which she had treated him in the first ardour of her passion. To entrust him with any responsible share in the government

Scotland. was impossible; and Murray's friends who remained at court, and watched the increasing estrangement between the Queen and her husband, determined to turn it to their advantage.

Mary promotes Riccio. Murder of Riccio. A.D. 1565. It was the misfortune of the Scottish queen that she had few or no servants whom she could trust. Her secretary, Maitland of Lethington, had betrayed her interests to Elizabeth, and was in disgrace, and, in the mean time, the queen had availed herself of the services of Riccio, her foreign secretary. This person had entered her service at first as a singer in her band, but afterwards, by his skill and fidelity, he raised himself to this confidential employment, much to the annoyance of the young king, who regarded him with peculiar aversion; and, incredible as it may appear, Darnley having persuaded himself that he had stolen from him the affection of the young queen, resolved to assassinate him. Nor was it difficult, among a fierce and unscrupulous nobility, to find associates in his flagitious schemes. His father the earl of Lennox, Morton the lord chancellor, Lethington the ex-secretary, Murray and his friends who were in banishment, and many of the stern supporters of the reformation, who suspected Riccio of intriguing with the papal court, willingly joined in the conspiracy. The parliament was at hand in which it was intended to pronounce sentence against the banished lords: it had been reported that measures were in preparation for the establishment of the Roman Catholic faith; and it was determined to arrest both the one and the other by striking the blow against Riccio. Accordingly, when Mary, who was then six months gone with child, sat at supper in a small cabinet adjoining to her bed-room in the palace of Holyrood, the king led the conspirators up a secret stair which communicated with the apartment, while the earl of Morton and a band of armed soldiers seized the gates of the palace. The countess of Argyll, Erskine, captain of her guard, the comptroller of her household, Riccio her secretary, and one or two domestic servants formed the queen's party, some sitting at table and others being in attendance. Indeed, the little closet or cabinet was so small that three or four persons could with difficulty have seated themselves. But its narrow dimensions prevented escape and favoured the ferocious purposes of the conspirators. Led by the king they burst into the cabinet, overturned the table, and threw themselves upon Riccio, who sprung for protection behind the queen. In a moment his fate was decided. One ruffian threatened Mary with his dagger, another held a pistol to her breast, a third, snatching the king's dagger, stabbed Riccio over her shoulder; and at last tearing him from the closet, amidst the shrieks of the women, and the shouts and execrations of the conspirators, they dispatched him, or rather cut him to pieces in an adjoining apartment, with fifty-six wounds.¹

Mary escapes, and drives the conspirators out of the kingdom. After this atrocious murder, which, considering the situation of the queen, might have cost her and her infant their lives, the conspirators detained her as a prisoner in her palace, permitted no one but the king and their own party to hold any communication with her; and having been joined next morning by the earl of Murray and the exiles from Carlisle, it was determined to make a complete change in the government. Darnley, weak and profligate as he was, they rewarded by placing at the head of their new system, being well aware that he would soon be their tool. The queen was to be confined in Stirling till she should consent to the full establishment of the reformed religion; and the earl of Murray and his associates were to be restored to their former favour and power. In a single day all these intentions were overturned. Mary, left alone with her husband, regained her ascendancy over him; she convinced him of the perfidy of Morton, Ruthven, and his associates,

Scotland. obtained from him a confession of all the secrets of the conspiracy, escaped with him to Dunbar, and being instantly joined by eight thousand men, advanced with such rapidity against the conspirators, that they fled in dismay to Berwick, and solicited the protection of Elizabeth.

Mary's difficulties. Darnley, in his confessions to Mary, had betrayed his brother conspirators, whilst he solemnly asserted his own innocence; but Morton and his associates produced in their own defence various bonds and letters, which were signed by the king, and fully established his guilt; and Mary saw, to her inexpressible grief and disgust, that the cruel outrage was planned by her husband. From this moment this miserable prince became an object of contempt and aversion to all. His conduct had been a tissue of cowardice, cruelty, falsehood, and weakness: to treat him with confidence, or to entrust to him any share in the government was impossible; and the unhappy queen, without a stay to rest on, fell into a state of the deepest despondency. Whom indeed could she trust? Murray and his party had but recently been rebels; Morton and his associates were stained by the blood of her confidential servant, murdered at her knees; the king was the chief conspirator, the queen of England had deceived her, the party of Knox and the Scottish church regarded her with avowed aversion; and even the Roman Catholics were somewhat estranged by the preference which at first she had given to their opponents. Under these complicated difficulties, the queen pursued the course which she deemed most likely to ensure success. She broke with none, pardoned some of the conspirators, affected to believe her husband, hoping even against hope, and restored Murray to some portion of the power of which he had been deprived. Such was the state of things, when, the period for her confinement having arrived, she gave birth to a son in the castle of Edinburgh. The child was named James Charles, and on the death of Elizabeth succeeded to the English throne.

Parties in the state. When her recovery permitted Mary to attend to the affairs of the country, it was apparent that unless immediate steps were taken to establish something like a strong government, the kingdom would fall to pieces; and yet such was the weakness and treacherous nature of the king, that to admit him to a share in it was impossible. She next turned to her nobles. Of these the most powerful were Murray, Bothwell, Huntly, Argyll, Lennox, Morton, and Lethington; but there had long existed a feud between Murray and Bothwell, while Morton, Lethington, Lennox, and their partizans were still in disgrace for the murder of Riccio. It was necessary to make an effort, and the queen succeeded in reconciling Murray to Bothwell: Huntly was made chancellor, Lethington was pardoned and restored to his office of secretary; while Murray, Argyll his brother-in-law, and Bothwell, were entrusted with the chief management of affairs.

Murderous courses. Enraged at his exclusion from power, the king sullenly retired from court, threatened to murder the earl of Murray, and at last declared he would leave the kingdom. It was in vain that his father remonstrated against his resolution; in vain that the queen herself, leading him before her council, conjured him to detail his grievances, and if she had injured him in any respect, to accuse her without reserve. He declared she had herself given him no cause of complaint; but afterwards, in a letter, he complained that he had no power in the state, that he was neglected by the nobility, and would bear it no longer. Soon after this the unhappy princess was seized by a fever at Jedburgh, during which her life was despaired of. Her enemies ascribed it to the injurious effects of a rapid ride which she took from Jedburgh to visit Bothwell, who had been wounded in a skirmish with some border thieves; it had more probably its origin in that anxiety which followed the conduct of Darnley; but he

¹ Keith's History of Scotland, p. 283.

Scotland. this as it may, she recovered only to be the victim of more aggravated sufferings. Partial reconciliations were followed by no revival of affection or confidence; and in the anguish of a wounded spirit, she sometimes lamented that she had not died at Jedburgh.

A divorce proposed. It was in this season of depression and despair that Murray and Maitland proposed to her a divorce from the king. They had previously confided their project to Huntly, Argyll, and Bothwell; and at first Mary seemed inclined to follow their advice, provided the divorce could be lawfully procured, and without prejudice to her child. But after weighing the whole matter her opinion changed, and when Maitland urged that means could be found to free her of Darnley without injury to her son, declaring that Murray would look on and say nothing against it, she broke off the conference. "I will," said she, "that ye do nothing through which any spot may be laid to my honour or conscience; let the matter be in the state it is, abiding till God of his goodness put remedy thereto."

Conspiracy for the murder of Darnley. Having failed in this device, a conspiracy for the murder of the king was entered into by Maitland, Bothwell, Huntly, Argyll, and Sir James Balfour. It has been disputed whether Murray was, or was not, a party to this atrocious design. It is certain that he did not sign the bond, by which, according to the custom of this age, the conspirators bound themselves to each other. There is a strong presumption, however, that he knew of its existence; and the deed was communicated to Morton and his associates, who signed it, and agreed to support the conspirators in the execution of their purpose. Such was the state of matters when the baptism of the young prince took place at Stirling. From this ceremony the king obstinately absented himself, alleging in excuse the neglect and rigour with which he was treated. Soon afterwards he left the court and retired to Glasgow, where he was seized with the small-pox, and appeared in imminent danger. His situation appeared to awaken the tenderness of the queen. She sent her own physician to wait on him, and soon after visited him herself, and ministered to his wants. When his convalescence permitted him to be removed, she returned with him to Edinburgh, and placed him, for the benefit of the air, in a house in the suburbs called the Kirk-of-Field. It was here that the conspirators determined to carry their dreadful purpose into effect. At the solicitation of Elizabeth and the French king, Morton had been pardoned and permitted to return; and in a secret interview between him, Maitland, and Bothwell, the particulars of the murder were arranged. Bothwell undertook the chief part, and his men having obtained access to the cellars of the Kirk-of-Field, undermined the foundation, and placed gunpowder in the cavities which they had formed. According to another account, they deposited it in the queen's bed-chamber, which was immediately under that of the king. While all this had been secretly carrying into effect, Mary continued her attendance upon Darnley: their reconciliation appeared to be perfect, she often slept in the house, and on the evening of the 9th of February, when she took leave of him to attend a marriage of one of her servants, which was to be held at the palace, it was remarked that she embraced him tenderly, took a ring from her finger, and placed it on his. On that night, after she had retired to her chamber in the palace, a sudden and terrific explosion was heard, which shook the city, and it was soon discovered that the Kirk-of-Field was blown up. The dead bodies of the king and his page were found at a little distance in the garden. It is well known that this miserable catastrophe has given rise to a celebrated historical controversy, in which authors of great name

and talents have taken different sides; some insisting that the queen was cognizant of the plot for the murder of her husband, and others as positively asserting the contrary. The limits of this historical sketch render it impossible that we should enter into its details.¹ In the preceding narrative we have carefully avoided the introduction of a single controverted fact; in the sequel we shall as sedulously follow the same rule.

Scarcely were the citizens of the capital recovered from the horror and dismay which was incident to such a calamity, when bills appeared on the walls of the Tolbooth, which accused Bothwell of the murder, and added that the queen had assented to it. Soon afterwards, the earl of Lennox, the unhappy father of the late king, earnestly required the imprisonment of the persons named in the anonymous handbills, and Bothwell declaring his innocence, demanded an instant trial. It was granted, and Lennox received due notice of it; but on the day of trial Bothwell appeared surrounded by upwards of four thousand of his friends and adherents; and Lennox, intimidated by the array, or finding it impossible to collect sufficient proof, requested an adjournment. This, however, was peremptorily refused, and the accused was acquitted by the jury, who considered it established by sufficient evidence that Bothwell could not have been at the Kirk-of-Field when the explosion took place.

Soon after this acquittal the Parliament assembled, and the majority of the nobility prevailed upon the queen to consent to an act by which all the grants of crown property which had been made during the present reign were confirmed, and herself and her successors deprived of all power of revocation. In the same assembly of the estates, the verdict passed upon Bothwell, which many accused as informal, was declared just and legal, and soon afterwards a bond was drawn up by twenty-four of the principal peers. It affirmed in solemn terms the innocence of this profligate baron, whom the public clamour still denounced as the murderer of the king; recommended him as a proper husband for the queen; and bound its authors, as they should answer to God, to defend him from all danger, and to promote this unhallowed marriage to the utmost of their power and ability. The tragedy now hurried on to its conclusion. Bothwell, at the head of a thousand men, intercepted the queen on her way from Stirling to Edinburgh, and carried her captive, with the slender suite by whom she was accompanied, to Dunbar castle. Among her attendants were Huntly, Maitland, and Melville, but the first two were in Bothwell's interest, and had signed the bond. The last was completely in his power, and so was the unfortunate queen. He proposed marriage, and on her refusal exhibited the bond signed by her nobles. She still, it is said, resisted his request, and hoped for a rescue; but it was a vain expectation. He became more peremptory, and if we may trust the expressions of Mary, corroborated by Melville and her enemies, he compelled her by fear, force, and other unlawful means, to yield to his wishes, and admit him to her bed. From Dunbar he now carried his victim to Edinburgh. A divorce was procured from his wife on the ground of adultery, and the process having been hurried through the court, and the sentence passed, Bothwell was married to the queen at Holyrood, within a month after his acquittal of the murder of her husband, (May 15, 1567.)

Events of the deepest and most tragic interest now crowded on each other. The nobles who had advised the marriage, who had acquitted Bothwell, and abetted him in his career of ambition and outrage, at once dropped the mask, assembled their forces, and declared their determination to separate the queen from the murderer of her husband. As

¹ The reader who wishes to make himself master of the controversy should consult for the Queen's innocence, the work of Goodall, and that of William Tytler, with the volumes of Stuart, Whitaker, and Chalmers; against her, the Histories of Hume and Robertson, with the Dissertation by Mr. Malcolm Laing.

Scotland. they advanced and occupied Edinburgh, the earl and the queen retired; but in a few days they found themselves strong enough to confront their enemy on Carberry hill, near Mary. Musselburgh. Both factions, however, seemed anxious to avoid a battle, and an extraordinary agreement took place. Bothwell, whom they had declared their determination to seize and punish as the murderer of his sovereign, was permitted, without molestation, to ride off the field. The queen was assured of their unshaken fidelity; and so completely did she credit their asseverations, that she gave her hand to Grange, and suffering him to lead her to his associates, was conducted by them to the capital.

Mary confined in Lochleven castle.

Within an hour she discovered that she had surrendered herself to her mortal enemies. On her entering the city, a furious mob assailed her with execrations, and displayed before her a broad banner bearing the figure of her murdered husband. Amidst these indignities she was carried to a house, where she was so strictly guarded, that not even her maids were allowed access. And on the succeeding evening she was conveyed by the lords Lindsay and Ruthven a prisoner to Lochleven, a strong castle in the middle of a lake, from which all escape seemed hopeless.

Mary signs her abdication.

A.D. 1567. From those who had thus shamelessly broken their solemn engagement, little else could be looked for but additional indignity and outrage. Mary was soon visited in her prison by lord Lindsay of the Byres, whose fierce temper and brutal manners peculiarly fitted him for the mission on which he was sent. He presented to her three written instruments. By the first she was made to resign the crown in favour of her son; by the second, the earl of Murray was nominated regent during the king's minority; by the third, a temporary regency was appointed to act until Murray returned from the continent. When Lindsay threw these deeds on the table, he plainly informed the queen that no alternative was left, but either to sign them without delay, or prepare for death, as the murderer of her husband. We are not to wonder that, aware that her life was in the hands of her bitterest enemies, Mary instantly obeyed.

Coronation of the young king.

The young king was now crowned, and Murray having arrived from France, assumed the regency, and entered upon the cares of government. He had not, however, for many months enjoyed the sweets of power, when the queen, by the assistance and ingenuity of a youth of sixteen, named Douglas, escaped in the night from Lochleven, and riding first to Seaton, and next day to Hamilton, soon found herself surrounded by a band of her nobles, and at the head of six thousand men. Mary was desirous to avoid war, and addressed repeated pacific proposals to the regent, who was then at Glasgow. She offered to call a free parliament; she was ready to deliver up to justice all whom he accused as guilty of the murder, provided those whom she arraigned of the same crime were also delivered up. This was peremptorily refused, her messengers were arrested, her adherents denounced as traitors; and the queen, aware that it must come to the decision of the sword, determined to await the arrival of additional forces, when she was hurried into an engagement with the regent, who threw himself in her way at Langside, as she was on her march from Hamilton to Dunbar. The result was calamitous. Her army was completely defeated, and she herself compelled to fly from the field with a slender train, who rode to Dundrennan, a distance of sixty miles, before they drew bridle. Next day she intimated her resolution of throwing herself on the protection of Elizabeth. From this step her friends passionately dissuaded her; but she declared she would trust to the assurances which she had received from her good sister; and crossing the Solway, she proceeded through Cockermouth to Carlisle. The return for this act of generous confidence and devotedness is well known. Elizabeth refused to see her, gave orders that she should be detained, kept her in

A.D. 1568.

prison a miserable and heart-broken captive for fourteen years; and at last brought her to the scaffold.

From the imprisonment of Mary, (1568,) till the accession of James the Sixth to the English throne (1603,) there is an interval of thirty-five years. It is occupied by the successive regencies of Murray, Lennox, Mar, and Morton, after whose execution we have that portion of the reign of James which extends from 1581 to 1603. With a rapid review of the most interesting and influential events during this period, we shall conclude our labours.

The imprisonment of Mary left Murray the undisturbed Regent of Scotland; but the queen strenuously and indignantly asserted her innocence of the atrocious crimes of which she was accused; and as the English queen could bring forward no possible justification of her conduct in detaining Mary, except her alleged accession to the murder, it was evident that an investigation of the circumstances, if demanded by the accused party, could not in justice be refused. Mary offered to hear the accusation of her enemies in the presence of Elizabeth, and in the same presence to undertake her defence; but this was denied her. It was then proposed by the English ministers that she should consent to a public trial; but this she rejected as beneath the dignity of an independent sovereign. It was lastly suggested that her enemies should be summoned to produce their proofs before certain English and Scottish commissioners, and that the cause should be left to their decision.

A commission was accordingly held at York, but it led to political intrigues rather than judicial investigation. After some interval Murray was summoned to hold a private interview with Elizabeth at Westminster; and Mary again demanded to be admitted to the same presence, and conducted with her accuser. This was denied, while the English queen permitted Murray to bring forward his charge, and to attempt to substantiate it by letters, affirmed to be in the queen's hand-writing, addressed to Bothwell, and conclusive, as he contended, of her guilt. Again Mary demanded by her commissioners to be heard personally in her defence; and this being refused, they protested against further proceedings, and declared the conference at an end. Cecil, however, insisted that the inquiry should proceed; and having procured all the evidence which he judged necessary, he attempted to persuade the Scottish queen, as the only way of avoiding an ignominious exposure, to resign her crown. Her reply disconcerted him. "They have accused me," said she, "of the murder of my husband. It is a false and calumnious lie. It was themselves that counselled and contrived the murder, some of them were even its executioners. Give me what I am justly entitled to, copies of the letters they have produced; let me see and examine the originals, and I pledge myself, in presence of the queen, to convict them of the atrocious crime they have had the audacity to impute to me." This bold and unexpected tone embarrassed Elizabeth; and Mary having repeated her charge, insisted on having copies of the letters produced against her. The English queen evaded the request, and advised her to resign her crown. To this she declared that no persuasion would ever induce her; and under such circumstances the conferences were abruptly terminated. Murray, with his associates, received permission to return to Scotland. He carried away with him those alleged original letters, which the party whom they inculpated was never permitted to examine; and he left behind him copies, which were also concealed from Mary and her commissioners. It is from these copies, which the accused was never permitted to compare with the originals, that future authors have been obliged to infer the guilt or innocence of the queen; and certainly, if the opinion of Elizabeth is entitled to weight, it is clear that she considered the proof as defective. She and Murray shrunk from a public challenge of Mary; and however suspicious or inexplicable some of the

Scotland. steps taken by this unfortunate princess may have been, her friends alleged that victory in the conferences at York and Westminster was on her side. Yet was she detained a captive by the very princess who had virtually declared her guiltless. All this might however have been anticipated; and no one who knew any thing of the unscrupulous policy of Elizabeth could have dreamed, that having once possession of the queen, she would ever permit her to return to her dominions. In her detention, she possessed the means of rendering Murray subservient to her wishes, of checking the Roman Catholic party, confirming the ascendancy of the protestants, and destroying the French interest and intrigues in Scotland. These were advantages with which no considerations of the individual guilt or innocence of her royal captive were likely to interfere.

Intrigues of Norfolk and Maitland.

The subsequent career of Murray was bold and brief. He found himself called to a contest with a party, headed by the duke of Norfolk in England, and by Maitland and Grange in Scotland, whose object was, the restoration of the Scottish queen, and her marriage to Norfolk. The project had been encouraged by the Regent, whether at first sincerely or for selfish and ambitious purposes, is not clear; but in the end he betrayed the plot to Elizabeth, and was the main instrument in bringing this unfortunate nobleman to the scaffold.

Murray's subsequent career.

The principles upon which his government was conducted were entirely protestant and English; and Elizabeth, who knew well and valued so able an assistant, cordially co-operated with him to overwhelm the queen's friends, and to extinguish all hopes of the Roman Catholic party in either country. But the task was more difficult than had been anticipated. She succeeded indeed in extinguishing the great rebellion, led by the earls of Westmoreland and Northumberland; but Murray found it impossible to prevent the intrigues of such men as Maitland, Grange, and their associates, who had known him long, and having assisted to raise him to the supreme power, were indignant to find themselves treated with severity or neglect. It was in the midst of this struggle between the regent and his former associates in ambition and guilt, that he was assassinated in the streets of Linlithgow, by Hamilton of Bothwellhaugh, who was incited to this act of revenge by a private injury, of which Murray was only the remote cause.

Murray is assassinated.

A.D. 1570.

State of parties in Scotland. Lennox chosen regent.

A.D. 1570.

His death found Scotland divided between two parties. On the one side were the Protestants who adhered to the young king, and regarded Elizabeth as their protector; on the other the queen's friends, who, being animated with the utmost rancour against their opponents, prepared instantly to appeal to the sword. Previously to this, however, they assembled a parliament at Edinburgh, and fulminated denunciations of treason against their enemies; while the protestants in their turn having chosen the earl of Lennox regent, convoked the estates at Stirling, and soon afterwards having made themselves masters of Dunbarton by a successful night attack, they took prisoner the archbishop of St. Andrews, who had shut himself up in the fortress, and executed him on the instant, without even the semblance of a trial. This outrage led to retaliation, and a civil war, remarkable for its ferocity, began to spread havoc through the country. On Mary's side were the duke of Chastelherault, the earls of Argyll, Athole, Huntly, Crawford, Rothes, and Cassilis, the lords Seton, Boyd, Gray, Livingston, Fleming, with the lairds of Buccleugh, Fernihirst, and many others; to whom we must add the able and crafty secretary Maitland, and the experienced soldier Kirkaldy of Grange. Of the king's party the nobles were neither so numerous nor so powerful. Lennox, Morton, Mar, and Glencarn, lords Lindsay, Glamis, Semple, Methven, Ochiltree, Cathcart, Ruthven, and some others, espoused this side; but if inferior in numbers, they were confident in the assistance of England, and in the support of the church, the commons, and the boroughs.

Such was the general comparative strength of each faction. Into the details of the contest we cannot enter; and indeed it had lasted but for a short time, when Lennox was slain in a skirmish at Stirling, and the earl of Mar, one of the most upright-minded and honourable noblemen in Scotland, was chosen to supply the vacant regency. To promote a reconciliation between the two factions, and to restore peace, order, and security of property, to a country distracted by intestine war, was the single purpose to which the new governor devoted himself; but he was thwarted by the ambition of Morton, and many of the higher nobles. These had so long been accustomed to derive individual advantage from public misery, that they laboured as earnestly to increase the contentions of the two parties, as Mar to remove them; and the governor, at last worn out by the struggle, and hopeless of effecting a reconciliation, sank into the grave.

He was succeeded in the regency by the earl of Morton, a man who has been justly described as possessing all the faults, some of the talents, but none of the good qualities of the regent Murray, of whom he was an old and tried ally. Sordid and selfish, implicitly devoted to the service of Elizabeth, whose countenance and support he felt necessary to enable him to retain his power, a venal judge, a cruel unrelenting soldier, a hypocrite in religion, and a profligate in private life, it is difficult to find a single virtue to relieve the dark monotony of his vices. Yet Morton had some of the great qualities which distinguished the house of Douglas. He was brave, decisive, politic; and he possessed that rapid power of discerning the instant to act with success, and that deep insight into human character which is commonly acquired by men of talent, bred up in scenes of civil commotion.

On his accession to the supreme power, the regent found the friends of the imprisoned queen still able to make head against him. The duke of Norfolk, who had been pardoned by Elizabeth, resumed his project of marrying Mary, and engaged in a correspondence with her. The duke of Chastelherault, and the earl of Huntly, lord Claud Hamilton, the lairds of Buccleugh and Fernihirst, with the indefatigable Maitland, and Grange, who was reputed the best soldier in Scotland, still supported her cause. Morton, however, strong in his own resources, and supported by Elizabeth, continued the war with success, and at last triumphed over opposition. Norfolk was brought to the scaffold, and the earl of Northumberland, treacherously delivered up by the Scottish regent, shared a similar fate. At last the castle of Edinburgh was invested by Sir William Drury, who joined the Scottish army with a formidable battering train. In this fortress, the single remaining hope of the queen of Scots, Kirkaldy of Grange commanded; and he held it bravely till the walls were destroyed, his guns silenced, and his provisions exhausted. Under these circumstances he surrendered, with his companion Maitland. To this step, Drury had induced him by a promise of favourable terms; but the English queen disregarded the stipulation, and handed over the prisoners to Morton. Kirkaldy and his brother were immediately executed, and Maitland only escaped the same scaffold by taking poison.

Morton now deemed himself so strong as to be independent of all parties, and his avarice and spoliations knew no bounds. He oppressed the church, of whom he had formerly affected to be the steadiest patron; and treated the young king and the nobles with so much haughtiness and severity, that he soon became an object of universal dread and hatred. James was now twelve years old, and it was not difficult for a faction of the nobles, who detested the regent, to persuade the young monarch that he ought no longer to be treated as a child. Acting by their advice, he accordingly summoned a parliament. It was numerous attended; and Morton, to the astonishment of all, the moment he learned the king's wishes, declared his willingness

Scotland. This ready and implicit submission was rewarded by the passing of an act of indemnity, which included a general pardon for any alleged transgressions, and ratified his whole conduct as regent. It is in his anxiety to procure this, that we are to find the secret of his sudden relinquishment of the supreme power; and scarcely was it procured when this extraordinary man, by means of a successful intrigue with a portion of the family of Mar, found means again to become master of the king's person, and re-emerged into as great power and ascendancy as before. His usurpation, however, was this time more short lived. Atholl, Argyll, and some of the most powerful nobles, assembled their forces, and declared their resolution to liberate the sovereign from his ignominious captivity. Instead of a battle, however, the opposite factions came to a compromise, by which the veteran tyrant was shorn of a large part of his power, and the young king recovered something of his independence.

James began now to show that strong propensity to favouritism which marked his future career; and the effects of this weakness were seen in the sudden rise into power of Esmé Stewart, duke of Lennox, and captain Stewart, second son of lord Ochiltree, and afterwards the notorious earl of Arran. Of these, the first was a high-born nobleman, of graceful address, amiable feelings, and common-place understanding; but the second, of birth and connections much inferior to Lennox, was ambitious, intriguing, daring, and unprincipled, and soon managed to gain an influence over both the young king, and the duke his favourite. With these advantages, an overwhelming opposition was soon raised against Morton; and as his exactions and cruelty had made him universally odious, it was in vain that his steady friend, the English queen, interposed to save him. Her interference indeed rather accelerated his fate, and the news that she meditated an invasion, roused the spirit of the young king and of his people to instant opposition. When Elizabeth, however, received intelligence that a Scottish army was assembled, she prudently withdrew from the contest; and Morton abandoned to his fate, was arraigned as an accomplice in the king's murder, at the instance of captain Stewart, who had recently been created earl of Arran. Of his guilt there can be little doubt, and he himself, after the jury brought in their verdict, and he had received sentence of death, acknowledged that he was privy to the intended murder. But his trial was conducted, even in those days of prostituted justice, with a reckless disregard of every form of law; and all were aware that the jury, of whom many were his bitter enemies, would, under any circumstances, have found him guilty. He died as he had lived, boldly, expressing a calm contempt of death, and exhibiting all the outward marks of repentance.

The death of Morton was followed by the nominal accession of the young king to the supreme power, but by the actual transmission of that power into the hands of his favourites, Lennox and Arran. This last nobleman, owing to the weak and flexible character of Lennox, soon came to rule all, and his rapacity, profligacy, and open defiance of public opinion, completely disgusted the nation. The result was a conspiracy for his ruin, headed by the earl of Gowrie. This nobleman and his associates having contrived to make themselves masters of the king's person, at the castle of Ruthven, and having removed Lennox and Arran from all authority in the state, directed the government as they judged best for their own interests. But the character of the king, although full of many strange contradictions, began now to exhibit a greater degree of talent and energy than his opponents were aware of; and although compelled to dissemble, and showing no symptoms of discontent with this change of masters, James was really disgusted with the durance in which he was held by Gowrie and his faction. With an ability which proved the more successful, because his

adversaries were unprepared for it, he contrived to organize a party, and free himself from his servitude; but it happened unfortunately that at this crisis the earl of Arran regained his liberty, and returning to court, soon resumed his baneful influence over the fond and facile monarch. It was by his advice that the king, who had first been inclined to use his victory over the faction of Gowrie with moderation, exchanged this wise resolution for vindictive measures; and although Elizabeth strongly remonstrated against it, he brought Gowrie to the scaffold, and drove his associates into banishment.

Arran was now supremely powerful; but the venality, Arran tyranny, and abuses of his government, soon became intolerable, and worked their own cure by producing a counter-revolution, in which the despotic favourite, after having first courted, and then quarrelled with the Scottish church, in vain attempted to recover his influence by means of the English queen, and was at last chased from court by the associated lords, who made themselves masters of the king's person. A government, upon a model which admitted the principal nobility to a share in the councils of the state, was now established; and Arran, deserted by all parties, sank into insignificance.

It was impossible that Mary, who had been detained a captive by Elizabeth, contrary to every principle of honour and justice, should not have exerted herself to regain her freedom; and the Roman Catholic party in England were not only interested in her success, but regarded her as their best security against Elizabeth and the Protestant faith. This led to a succession of intrigues, which were discovered by the penetration and activity of Elizabeth's ministers, the discovery only serving to increase the rigour of her confinement. At last the Scottish queen having been arraigned (unjustly as afterwards appeared) of an accession to the conspiracy of Babington, the object of which was the assassination of Elizabeth, and the restoration of the ancient religion, she was brought to trial before a commission, whose jurisdiction she at first peremptorily declined as an independent and sovereign princess. It was unfortunate for Mary that she did not continue in this resolution; but in the idea that a refusal might be construed into an admission of guilt, at last condescended to plead. The consequence was, what might have been expected from the nature of the evidence, the constitution of the court, and the supreme authority of Elizabeth. Mary was found guilty of having compassed divers matters tending to the death of the queen; and after many affected delays, and an atrocious attempt to induce her keeper, Paulet, to dispatch her secretly, Elizabeth signed the warrant for her execution, which was carried into effect on the 7th of February 1587. The meekness with which she received the intimation of her sentence, and the admirable and saintly fortitude with which she suffered, formed a striking contrast to the despair and agony which not long afterwards darkened the death-bed of the English queen.

It might have been expected that if any thing could have roused the king of Scots, it would have been the cruelty and injustice to which his mother had fallen a sacrifice; and for a moment there was an ebullition of indignant feeling. But Elizabeth sent him an artful apology. The blame of the execution was laid upon Davison, her secretary, an innocent and upright man, who simply obeyed her orders; and with that unscrupulous falsehood which this princess seldom hesitated to employ when necessary to carry through her designs, the unfortunate statesman was sacrificed, that his royal mistress might escape. But the English queen had still a firmer hold over the young king of Scots. He regarded the succession to her throne as his undoubted right, and dreaded to irritate her personal feelings, or alienate her Protestant subjects, by appearing to place himself at the head of the Roman Catholic party, who burned to avenge the death of their royal mistress. In vain, therefore, they

Scotland. looked to the king, who, after a short interval, relapsed into his usual pacific frame of mind, and celebrated his entrance upon majority, by an attempt to abolish those sanguinary feuds amongst his nobility, which had increased to an alarming height, and threatened to pull the country to pieces.

James VI. A.D. 1567. This laudable endeavour, which did not meet with the success it merited, was followed by James's marriage to the princess Anne of Denmark; an alliance which Elizabeth, with her usual jealous and capricious policy, endeavoured to prevent. But the Scottish king, with unwonted spirit and energy, sought his bride in person in her father's court, and having solemnised his marriage at Upslo, returned with her to Scotland.

The earl of Bothwell's attempt to seize the king. During his absence the kingdom had been unusually prosperous and happy; but it was soon afterwards embroiled by the intrigues and ambition of the earl of Bothwell, who, leaguings with the Roman Catholic faction, attacked the palace of Holyrood with the design of seizing the king's person, and placing himself at the head of the government. A second attempt of the same kind at Falkland was not more successful; and yet such was at this time the impotent state of the law, and the weakness of the royal authority, that these repeated treasons escaped unpunished, and Bothwell lived not only to defend but to repeat them.

State of Scotland. Scotland at this moment presented a melancholy picture. The intrigues of Philip the Second had encouraged the Roman Catholic faction, which was led by the earls of Huntly, Errol, and Angus; and James, aware of the great power possessed by the Romanists, both in Scotland and England, was fearful of treating them with severity, lest he should raise a formidable opposition to his right of succession, which must open on the death of Elizabeth. But this was not the only source of disquiet. The excessive lenity of the king had fostered the feudal quarrels among his nobles, impunity led to new excesses, and the turbulent and audacious Bothwell once more appeared upon the scene, and made repeated attempts to seize the royal person, and administer the government at his pleasure. To these sources of disquiet, were added the interference of Elizabeth, which roused the jealousy of the king, and the intolerant spirit of the protestant ministers, who, horror-struck by the discovery of the intrigues of the Roman Catholic lords, recommended their being treated with the utmost severity.

James attacks the Catholic Lords. Violence of the ministers. These combined causes transformed the kingdom into a scene of almost perpetual tumult and bloodshed; but the monarch at last becoming convinced of the treasonable purposes of the popish earls, assembled an army, and reduced them to the last extremity of distress. Bothwell, too, was driven into exile, and the country began to breathe anew, when James found himself involved in a contest with the protestant ministers. The cause of this dispute was the king's wish to lean to the side of mercy in his conduct to the popish lords. It was reported that Huntly, their leader, had been admitted to a secret interview. The clergy, alarmed to the utmost, appealed to their congregations; they defended the conduct of Black, a minister who had openly attacked the court and the queen, in a seditious harangue; they haughtily declined the authority of the privy council; and by their violence, they excited a tumult in Edinburgh, which compelled the monarch to retire to Linlithgow. Under these trying circumstances, the king acted with extraordinary energy, and jealous of so bold an interference with his prerogative, restored tranquillity to the capital, punished the insurgent citizens, compelled the ministers to fly to England, and, according to his original intentions, extended his forgiveness to the popish lords who made a recantation of their errors.

James's plan for introducing Episcopacy. James, who had been alarmed at the late violence exhibited by the presbyterian clergy, now became intent upon

a plan for new-modelling the church, but aware, that if the measure originated in any other quarter than that of the clergy themselves, it would inevitably miscarry, he artfully prevailed on the General Assembly to second his views. The commission appointed by this ecclesiastical council were induced to complain that the church was the only body not represented; and the king, whose object it was to restore episcopacy, procured an act to be passed, by which those ministers upon whom he had conferred the vacant bishoprics and abbeys were entitled to sit in parliament. When this measure came again to be debated in the General Assembly, it encountered great opposition. "Deck these intruders as you will," exclaimed one of the most zealous presbyterians, "under all their disguise I see the horns of the mitre." Yet after a long debate, a majority of the General Assembly declared in its favour; and it was resolved that ministers might lawfully accept a seat in parliament, and that fifty-one members should be chosen as representatives of the church in the supreme court of the country. When, however, the question arose regarding the spiritual jurisdiction which should belong to these persons, the General Assembly so effectually shackled and abridged their powers, that they remained wholly dependant upon this great ecclesiastical council, and exercised no separate spiritual jurisdiction. It was James's hope, that, in the course of time, they would shake off these fetters, but, in the mean time, they could claim none of the privileges belonging to the episcopal order.

When the monarch was thus employed, and his kingdom was enjoying a degree of tranquillity to which it had been long a stranger, the minds of the people were suddenly agitated by a sudden and mysterious attempt made at Perth upon the life of the king by the earl of Gowrie and his brother, Alexander Ruthven. These young men were the sons of that earl of Gowrie who had been executed for treason, and it is probable that a desire to revenge their father's death led to their miserable and ill-concerted enterprise; but much obscurity hangs over the whole transaction. It is certain that Ruthven induced the king, by a feigned story, to accompany him with a slender train from Falkland to his brother's house at Perth. Here he contrived to separate James from his attendants, and leading him into a remote apartment, threw himself upon him, seized him by the throat, and drew his dagger. The king struggled to get to the window, and calling out treason, alarmed his nobles, who rushed into the room, stabbed Ruthven to the heart, and when Gowrie attempted a rescue, put him also to death on the spot. Both these unfortunate men being slain, the utmost pains were taken to detect their associates, to unravel the plot, and to ascertain their precise object, but with so little success, that to this day the mystery is not solved.

The queen of England, now in her seventieth year, began soon after this to droop, and her constitution, hitherto uncommonly vigorous and unimpaired, was evidently breaking up. Of all this James was well aware. He had secured the friendship and good offices of Sir Robert Cecil, her chief minister, who, unknown to his mistress, carried on a secret correspondence with the Scottish king; and acting by his advice, he had employed every effort to conciliate the affections of the English people, and to acquire the support of the most powerful of the English nobility. These judicious precautions were attended with the wished-for result. James was Elizabeth's undoubted heir; and on the death of this princess, an event which took place on the 23d of March 1603, he succeeded, with the unanimous consent of the nation, to the throne of England. This great and auspicious event closes the history of Scotland as a separate kingdom.

(P. F. T.)

STATISTICS.

Statistics.

Physical
features
and geo-
logy.

The mainland of Scotland lies between 54. 38. and 58. 41. N. Lat., its extreme points being the Mull of Galloway in the south and Dunnet Head in the north. It extends from 1. 46. to 6. 14. W. Long., from Peterhead on the east to Ardnamurchan Point on the west coast. Its greatest length, nearly due north and south, in 5. W. Long., from the Mull of Galloway to Cape Wrath, is about 280 miles; its greatest breadth, from Buchanness to the coast of Applecross, above 150 miles. From the Firth of Forth to the Clyde, and from the Dornoch Firth to Loch Broom, the distance is scarcely 30 miles. The extent of sea-coast, from the numerous indentations on the western shore, is very great, or probably above 3000 miles. Its area is still very uncertain, the mainland being estimated at from 25,500 to 26,400 square miles; of which about 500 are occupied by fresh-water lakes. Including the islands, the total extent is 29,600; or in round numbers, 30,000 square miles. St Kilda, the most remote of the Hebrides, lies in 8. 35. W. Long.; Lanbaness, the most northern point of Unst in Shetland, in 60. 49. N. Lat.

The physical features of this country, as of other regions of the earth, are intimately connected with its geological structure. In this respect Scotland forms three very strongly marked divisions, which are better described separately. These are, *first*, the Southern Division, or region of the older Palæozoic or Silurian formations; *second*, the Central Division, or region of newer Palæozoic, or Devonian and carboniferous formations; and *third*, the Northern Division, or region of the crystalline and metamorphic formations. The islands on the west and north form a portion, or rather a kind of appendix, to the last division. Each of these we shall notice in the order now indicated.

I. The Southern, or older Palæozoic region, extends from the border of England to an irregular line running E.N.E. from the Firth of Clyde, near Girvan, by Dalmellington, Crawfordjohn, Skirling, and the north base of the Moorfoot Hills, to the east coast near the Siccar Point. It consists predominantly of a great formation of Lower Silurian strata, broken through at intervals by felspar-porphyrtes, trap-rocks, and, in Kirkcudbright, by large masses of granite and syenite. The strata have been forced up in various anticlinals and convolutions; but the lowest beds occur along a line from the vale of the Teviot to the vicinity of Dumfries; the newer deposits, chiefly near the northern margin. These strata form an extensive mountain range, known as the Southern Highlands, and crossing the island in a series of connected chains from St Abb's Head to Stranraer and Loch Ryan. Taken generally, the mountains show broad flattened forms, intersected by deep, pastoral glens, widening out into broader valleys or dales along the course of the principal rivers. The mountains are rarely rocky or precipitous, but covered by grass and moss to their summits, which seldom rise above 1500 to 2000 feet. The greatest elevations are found in Peeblesshire and Dumfriesshire, near the sources of the Tweed, Clyde, and Annan, where Dollar Law (2680 ft.), Broad Law (2754 ft.), White Comb Edge (2695 ft.), Hartfell (2638 ft.), and Ettrick Pen (2268 ft.), are some of the culminating points. Farther east, Dundreich (2004 ft.), Windlestraw Law and Blackhope Scar (2130 ft.), are among the highest summits. On the west, the Lowther Hills (2522 ft.) and Queensberry Hill (2279 ft.), between the Annan and Nith; the Black Larg (2890 ft.), and Cairns Muir of Deugh (2597 ft.), between the latter river and the Dee; and beyond the latter, Merrick Hill (2764 ft.), are worthy of note. Criffel (1867 ft.) is conspicuous from its position. The Cheviots, on the border of England, with Cheviot (2668 ft.) and Carter Fell (1502 ft.), are a parallel group, but of very distinct formation, consisting of felspar-porphyrty, and trap-rocks, breaking through

Statistics.

and elevating the lower carboniferous strata. Connecting these two chains some isolated mountains range along between the sources of the Teviot and Liddel, including the Wisp Hill (1950 ft.), the Maiden Paps, and Great Moor Fell.

The valleys are best noticed in connection with their respective rivers. Of these the most important is the Tweed, with a length of 100 miles, and draining a basin of 1800 square miles in Scotland alone. The upper part of its course is chiefly in longitudinal valleys, parallel to the Silurian mountain-ridges. Below the junction of the Lyne, it intersects the main chain by a series of transverse hollows; and receiving on the left the Leithen, Gala, and Leader; on the right, the Manor, Quair, Yarrow, and Ettrick, it enters the lower valley near Melrose. Here it is joined by the Whitadder from the north, the Teviot on the south, and flows along the fertile plains of the Merse to the sea, at Berwick. This district, with the connected portions of Roxburghshire, forms some of the most fertile land in Scotland, resting on the upper old red and carboniferous formations, broken up by craggy knolls of trap, the sites of many of those ancient keeps famed in Border story.

Farther west are the vales of the Liddel, Esk, and Annan; wild and pastoral in their higher portions; more cultivated where they traverse the carboniferous and new red or Permian strata, forming the shore of the Solway Firth. The low ground in this district is in many places covered with deep accumulations of peat (Solway Moss and Lochar Moss), concealing the remains of ancient forests, but now rapidly being converted into arable fields under the progress of modern improvements. The Nith, 58 miles long, rises on the north side of the Southern Highlands, and traversing them by a deep valley, partially filled with carboniferous and Permian deposits, has few important tributaries. Its valley, too, is comparatively narrow, but in many places beautifully wooded and fertile. The Dee, 45 miles long, has its sources in the wild granite mountains south of Loch Doon, and is joined by the Ken, where they expand into the long narrow lochs of the same names. Beyond the granite eruptions of the Cairnsmuir and Loch Doon mountains the country rapidly declines into low undulating moors, and the rivers Cree, Luce, and Stincher, have no peculiarities worthy of notice.

Loch Doon, 6 miles long by 1 broad, Loch Ken in Kirkcudbright, already mentioned, and St Mary's Loch in Selkirkshire, more celebrated for poetic associations than for its magnitude, are the only lakes in this district deserving mention. The others are mere mountain tarns; and the rarity or absence of these accumulations of water is one of the most striking contrasts between the southern and northern divisions of the country. Springs are everywhere common in the mountain districts, but rarely remarkable either for their size or other properties. The mineral springs of Moffat and Innerleithen are the only ones celebrated for their medicinal qualities.

Notwithstanding its mountainous character, this region produces very little mineral wealth. Lead ore has been mined for centuries at Leadhills in Lanarkshire and Wanlockhead in Dumfriesshire, and very recently with considerable success. The ores contain a considerable proportion of silver, which is extracted from them at Wanlockhead, and gold was formerly gathered from the alluvial deposits in that vicinity. Attempts to work lead have been made in various other places; antimony ore occurs near Langholm and New Cumnock, and copper mines have been opened in several localities in Kirkcudbright. Coal is only wrought near Canonbie, in Dumfriesshire; and lime, except in connection with the carboniferous strata in Roxburgh and Dumfries, only in some thin beds on the Stincher, in Ayrshire.

Statistics.

II. The central or newer Palæozoic region of Scotland contains only about 5000 square miles of extent, or less than one-fifth of the mainland, but is by far the richest and most important in a political point of view. It embraces the basins of the Firths of Clyde, Forth, and Tay; the upper sources of these rivers lying in the southern and northern divisions. On the south it is bounded by the line already mentioned, and on the north by another nearly parallel line, from the mouth of the Gare Loch on the Firth of Clyde, to Stonehaven on the east coast, passing near Aberfoyle, Callander, Comrie, south of Dunkeld, Cortachy, and Fettercairn. Geologically, this region consists of the Devonian, or old red sandstone, and the carboniferous formations, broken through or covered over by extensive trap-rocks. The old red sandstone is chiefly seen on the sides of the valley, being concealed in the centre by the carboniferous beds. The most extensive mass is on the north, where it runs continuously from the Clyde and lower end of Loch Lomond, through Stirling, Perth, and Forfar shires, to the shores of Kincardineshire on the east. The lower beds, or Forfarshire flagstones, marked by their characteristic fossils (*Cephalaspis*, *Pterygotus*, &c.), are extensively quarried and exported, as the well-known Arbroath pavement. Near the mountains a coarse conglomerate or pudding-stone prevails, which, in the gorges cut by the rivers in their descent, forms some of the most picturesque scenery in Scotland, as Brack Linn, near Callander; Monzie; Craighall, on the Erich; Lintrathen, on the Isla; Cortachy, on the South Esk; and the Burn, on the North Esk. On the Tay, below Perth, higher beds of the old red occur with peculiar fossil-fishes (*Holoptychius*, &c.), as at Clashbennie and Balrudery. The carboniferous formation consists of two divisions, the Lower, including the mountain limestone, with thick masses of sandstone and shale, and the Upper or Coal Measures, containing the chief beds of workable coal. The whole formation covers an area of 1500 square miles, of which, however, less than two-thirds, or 600,000 acres, contain workable coal. The beds wrought are generally one to two or three yards in thickness; those of greater dimensions, like the Dysart main coal, seven yards thick, being made up of several beds of coal, alternating with shale. Besides the coal, clay ironstone in vast abundance, and especially the valuable black-band, occurs in most portions of the formation. Less important are the beds of fire-clay used for bricks and crucibles; and the alum shales, from which alum and other chemical products are manufactured. The annual value of the mineral products of this part of Scotland cannot be estimated at less than—

Iron, two and a half to three millions sterling.
Coal, three to three and a half do.
Lime, &c., one and a half to two do.

or, on the whole, from L.7,000,000 to L.8,000,000 sterling.

The larger masses of igneous rocks in this district are generally found forming the hills; but where they occur in the low grounds, as in East Lothian, from their varied composition, add much to the fertility of the soil. The high grounds can scarcely be designated mountains; the chief group south of the Forth being the Pentland Hills, with Carnethy (1881 ft.), the Kipp Hills (1806 ft.), and W. Cairn (1859 ft.), as their highest summits. Beyond the Clyde, Tinto Hill (2308 ft.) connects this range with Cairn Table, and other summits, in Ayrshire. North of the Forth, the Kilpatrick, Campsie, Ochil, and Sidlaw Hills, from an almost continuous range of trap-rocks, interposed between the old red sandstone and coal formation. The Kilpatrick Hills, commencing near Dumbarton, on the Clyde, are a low but picturesque group. The Campsie Fells are also little elevated (King's Seat, 1510 ft.), and more undulating and uniform in outline. The western portion of the Ochils attains greater heights, as in Dun Myat (1345 ft.), Ben

Statistics.

Cleugh (2352 ft.), and the King's Seat (2100 ft.); but the eastern portion along the Tay falls to 300 or 400 feet. The Sidlaws, in Forfarshire, are composed principally of lower old red, elevated by trap, with Dunsinnan Hill (1114 ft.) and Cairn Owl (1100 ft.), as remarkable points. Some of the lower trap-hills in this district, as North Berwick-Law (612 ft.), Arthur Seat (823 ft.), the Lomond Hills (1471 ft.); and the rocks on which Edinburgh, Stirling, and Dumbarton Castles are built, are conspicuous objects from their isolation.

This district is drained by three of the chief rivers of Scotland,—the Clyde, Forth, and Tay, with others of less importance. The first of these, the Clyde, is the only large river flowing to the Western Sea. Rising in the centre of the southern Highlands, and flowing first N. and N.E., till near Biggar, it then bends round the base of Tinto, and joined by the Douglas and other tributaries, runs N.W. to the Firth, below Greenock. The well-known falls occur near Lanark, where the river is changing its course, the first, that of Bonnington, being about 30 feet high; the second, Coira Linn, about 70 feet, and the third, Stonebyres, not less than 76 feet, but broken into three falls. Above the Falls the valley is often bleak and moory, but lower down becomes more fertile, richly wooded, and adorned with numerous orchards and thriving towns and villages. At Glasgow, the river becomes navigable, the shoals and other obstructions being removed by dredging, and the water straightened and confined by artificial banks. The total length of the Clyde is about 90 miles, and its basin under 1500 square miles. The Firth into which it falls is rather one of the great indentations of the western coast, than a portion of the river; but is very important as conveying commerce and wealth into the centre of the richest mineral district in the country.

The Forth rises near Ben Lomond, and is joined above Stirling by the Teith, a larger and longer stream. In their upper course, amidst the Highland mountains, they are wild and rapid rivers; but after entering this district their course is slow and winding. The total length of the Forth above Alloa is about 50 miles; of the Teith, to the same town, about 65 miles. The banks of the river are formed by low alluvial plains or *carses*, remarkable for their fertility, and producing rich crops of wheat and other grains. They have evidently been submerged by the sea till a recent geological period; and from Blairdrummond westwards are often covered by peat, a still more recent accumulation, apparently formed in some cases since the island was first invaded by the Romans. The tide flows to Stirling; but the Firth is considered as beginning at Alloa, from which it extends for 50 miles to the Isle of May. The Carse lands continue to Borrowstounness, whilst the lower shores in Fife and the Lothians comprise some of the most fertile and best cultivated land in the kingdom. The Firth, too, expanding from 2 miles wide at Queensferry to 6 at Leith, and 15 to 10 lower down, is one of the best natural harbours of refuge on the east coast of Britain, and consequently, from an early period, one of the chief seats of Scottish commerce.

The Tay, the monarch of Scottish, and in size of basin and amount of water carried to the sea, probably also of British rivers, rises in the northern region. The main stream has a length of 100 miles above Perth, or 130 miles to the opening of the Firth at Buddon-Ness. Its basin comprises about 2400 square miles, or one-eleventh of the mainland, about three-fourths belonging to the river above Perth. It is also remarkable for the number and size of its tributaries,—the Garry, Tummel, Lyon, Earn, Isla, and Erich, and the wide range of country from which they draw their waters. We shall notice the upper portion in connection with the northern district, to which it naturally belongs. Its lower basin falls chiefly in the valley of

Statistics.

Strathmore, inclosed between the Grampians on the north, and the Ochils and Sidlaw Hills on the south. This great valley, including Strathearn, has an undulating surface, but nowhere rises far above the sea-level. It is thickly covered with alluvial matter, resting on the old red sandstone, and the soil, consequently, is highly fertile. The Carse of Gowrie, between the Sidlaws and the Firth of Tay, has long had the reputation of possessing the richest and most productive soil in Scotland, derived probably from the decomposing trap-hills which shelter it on the north. The South Esk, 40 miles long, and terminating in the wide but shallow bay of Montrose, nearly dry at low water, and the North Esk, traverse the northern part of this district. In physical features and capabilities, this tract is a mere continuation of the valley of Strathmore, the most marked peculiarity of the plains of Kincardine being the deep red tint of the soil. The precipitous character of the coast, well seen at the Red Head, and north from Bervie to Dunnottar, is interesting as proving the waste which the conglomerate and other hard beds of the red sandstone have undergone from the action of the sea.

Like the southern region, the centre of Scotland is remarkable for the rarity and small size of its lakes. Loch Leven, in Kinross, 4 miles long by 2 broad, is scarce an exception, and is best known for the picturesque ruins of its island-castle, the scene of Queen Mary's imprisonment and romantic escape (1568) previous to the battle of Langside, and her ill-fated flight into England. It produces abundance of excellent trout, the fishery being let for a considerable sum, and was long remarkable as the only Scottish lake that yielded any revenue to its proprietors. The springs in this district also have little interest. Some in the coal formation are strongly impregnated with iron; and a few near the intrusive igneous rocks contain so much mineral matter as to be used for medicinal purposes. The best known of the latter are, Airthrey, Pitcaithley, and St Bernard's, near Edinburgh.

III. The northern division, or the region of the crystalline and metamorphic rocks, comprises the whole country north and west of the boundary line of the central division, drawn from the Firth of Clyde to Stonehaven. It contains above 19,000 square miles, or fully two-thirds of the whole country; and though generally far inferior in fertility and population to the other divisions, is in many respects more interesting in its structure and physical features. The western portion is usually named the Highlands, occupied by a people chiefly of Celtic descent, and still retaining their old language, and many peculiarities of habits and modes of life. No well-defined limit separates the north Highlands from the Lowlands on the east coast. After crossing the Spey, however, near Charlestown, the boundary line between the Celtic and Lowland population almost coincides with that dividing the crystalline rocks from the districts coloured in the geological map as belonging to the old red sandstone and newer formations. We may also mention that, though named Highlands, this term is only applicable to the elevation of the mountains, the inhabited and cultivated ground along the river-valleys and sea-coasts, being usually, at a lower level than many of the dales in the southern division.

The geological structure of this vast region, and the boundaries of the formations, can only be understood by reference to a geological map,¹ and we here chiefly notice the points bearing on its physical characteristics. Its southern boundary is formed by a narrow zone of clay-slate, commencing in Arran and running along the foot of the Grampians to near Stonehaven. In many places it is quarried for roofing-slates, and might be in many others, if required for the wants of the country. This rock again

Statistics.

appears in the north of Aberdeen and Banff shires, and on the west coast, in a thin band from Islay to Fort-William. In all these localities it is also wrought for economic purposes, particularly at Easdale and Balahulish, and is everywhere distinguished from the similar rock in the south by its distinct cleavage. The next formation to the north is the micaslate, which, commencing in the lofty cliffs of the Mull of Cantyre, forms the greater part of that curious peninsula in a series of low, rounded hills. It extends along the west coast to Loch Melfort, where it meets the trap-hills of Lorn, and thence N.E., in loftier and more picturesque ridges, through the upper part of Perthshire to Glen Prosen, in Forfarshire. There it contracts greatly, but still forms a continuous band, on the southern declivity of the Grampians, to the east coast. A less extensive mass forms the east side of Loch Linnhe and the Great Glen from Loch Etive to Fort-Augustus, including the lower parts of Glencoe, the valley of the Spean, and Glenroy, with its singular parallel roads. Other portions of mica-slate occur in Banff and Aberdeenshire, and again in the north of Sutherland. It is often, especially near Loch Fyne, associated with chlorite and talc slates. It is rarely turned to any other use than as a coarse building stone and imperfect roofing slate; but its lofty mountains, with ridged and serrated summits, and its valleys fringed with natural wood and adorned with long winding lakes, form some of the finest and most romantic scenery in Scotland.

The next formation is the gneiss, covering about 10,000 square miles, or fully one-third of the whole country. One great mass, commencing on the outskirts of Ben Cruachan, stretches N.E. along the Grampians to the shores of Kincardine and Aberdeen, from Stonehaven to Fraserburgh, and north through Inverness to the higher parts of Nairn and Elgin. This tract, especially on the N.E. line, is everywhere broken by granite, in some places in mere veins, in others in mountain masses. Another equally extensive gneiss region extends on the west of the Great Glen, from Morven and the Sound of Mull, through Inverness, Ross, and Sutherland to the extreme northern coast of Scotland, between Cape Wrath and Caithness. The Long Island, or outer Hebrides, is a third corresponding mass, once perhaps equally wide-spread, though now only the scattered fragments forming these islands remain. In the two latter tracts, granite in large masses is less common than in the first, but still abounds in veins, especially in the Hebrides and on the western shore of Sutherland and Ross. In mineral character the gneiss varies greatly from coarse crystalline varieties, scarce distinguishable from true granite, to fine-grained, distinctly schistose and stratified rocks. The general dip of the beds is at moderate angles to the S.E.; but in Sutherland and Ross, particularly on the west coast, S.W. dips with a N.W. strike prevail. Different parts of this vast formation may not improbably be of diverse age. On the N.W. coast it underlies all the other formations; in the centre of Sutherland a newer gneiss has been supposed to occur; whilst in the Southern Grampians this rock is apparently superior to the mica slate. Except as a building stone the gneiss has no economic value, and in this country is singularly devoid of mineral wealth. As a general rule, too, the regions formed of this rock are far from picturesque,—wide moory straths, rounded lumpish hills, and dark, irregularly winding lakes, with treeless shores, are the characteristic features.

The other primary rocks in this region require no notice, except quartzite, found in considerable abundance, as subordinate or superior to gneiss, in the Grampians of Perth, Aberdeen, and Banff. The range of the granite has been already noticed, forming some of the highest summits of the Grampians, Ben Macdui, Cairngorm, Loch-na-Gar, and

¹ See *Geological Map of Scotland*, by Professor Nicol, Edinburgh, 1858.

Statistics.

Mount Battock; but often also seen in the low grounds, as in the Moor of Rannoch and the plains of Aberdeenshire. Porphyry is the most important of the other igneous rocks, occurring in large mass near Inverary, composing the wild buttressed mountains of the dark Glencoe, and in the summit of Ben Nevis (4406 ft.) forming the culminating point of the whole British isles.

The next formation in the ascending series, is the red sandstone of the west coast, with the superposed quartzite and limestone, till lately regarded as equivalent to the old red sandstone on the east side of the island, but now as a much older formation. Fossil shells of species found also in the Lower Silurian strata of North America, occur in the limestone of Duirness; and this rock, with the quartzite, is now classed by Sir R. I. Murchison as Lower Silurian, and the inferior red sandstone as Cambrian.¹ The red sandstone, resting in nearly horizontal beds on a great water-worn plateau of gneiss, and covered in the interior by quartzite, forms a series of most peculiar and majestic mountains, almost from Cape Wrath down to Applecross and Skye. First in order, from the north, are Foinaven (3015 ft.) and Arkle, their summits of dazzling white quartzite, mistaken by Pennant for marble. The isolated conical Stack was proposed by Macculloch as favourable for repeating the Schiehallien experiment on the density of the earth, but is in too close proximity to some more gigantic neighbours. Ben More Assynt (3281 ft.) is the chief of another noble group, with Queennag, Canisp, and Sulven as outlying members. Sulven, or the Sugar Loaf, named from its conical appearance from the sea, but in reality a long serrated ridge, is a well-known landmark on the western coasts. Coul More, Coul Beg, and Ben More Coygach, north of Loch Broom, with Ben Goolish and Kea Cloch, on the south, are also remarkable mountains. Ben Lair, Sleugach, and Ben Ey, on Loch Maree; Leagach and Ben Alligin (3015 ft.) in Gairloch, with some less known summits between Loch Torridon and Loch Carron, may complete this enumeration. Carved out, as it were, by denudation, from the solid mass of sandstone and quartzite, these mountains show the waste which the land has undergone more strikingly than any other part of the British islands.

The old red sandstone, or Devonian formation, covering most of Caithness, on the mainland, and spreading north over the Orkneys and part of Zetland, again appears south of the Scarabins and Ord, bordering the Dornoch and Moray Firths on the west. It then fills the Great Glen to Meal-fourvonie and Foyers, and stretches by Culloden and the plains of Nairn and Moray to the east side of the Spey, reappearing in patches in Banff and near Aberdeen. The great conglomerate is regarded as the lowest portion; the Caithness flags, with their singular extinct fishes, and extensively quarried, are the central group; whilst the light red sandstones of Duncansby, Dunnet Head, and Hoy Head, in Orkney, are the upper division. The fine yellow sandstone of Elgin, remarkable for its numerous reptilian remains (*Telerpeton*, *Stagonolepis*, *Hyperodapedon*), is still included in this formation, though probably a newer group.

The newer secondary deposits occur in such limited extent that they exert no influence on the physical aspect of the country. The most important on the east coast are the patches of lias and oolite found in the north of Aberdeenshire, at Elgin, near Cromarty, and along the Sutherland coast from Dunrobin to Helmsdale, where, at Brora, they contain workable coal. The greensand and chalk flints found in Aberdeenshire, though curious, are of less importance. On the west coast, lias and oolite beds are widely

dispersed round the shores of Skye, Mull, and some other of the islands, and in Morven, Arisaig, and Applecross on the mainland, but now form no continuous tract. The trap-rocks covering them in Skye, Mull, and Morven, and also wide-spread on the mainland in Lorn, show that this part of Scotland has been for a long period the seat of a powerful volcanic action. Like the connected trap formations in the north of Ireland, some portions, as those overlying the Ardtun Leaf-beds in Mull, cannot be more ancient than the Eocene tertiary.

The country formed of these various rock masses may be described generally as a great plateau, deeply cut into valleys, and crowned with mountains rising to 2000 or 3000, and occasionally even 4000 feet of elevation. The distribution of these mountains in chains or other groups is often very obscure, especially on the west side of the Great Glen. The Grampians, from Argyle to Aberdeenshire, show the most marked linear arrangement, often, however, rather indicated by the river-valleys and lakes than by the mountains themselves. In Argyle, on the west, the mountains are by no means high, but attain greater elevations near the head of Loch Long and Loch Fyne, where Ben Una, the fantastic Cobbler (2863 ft.), Ben Ima (3300 ft.), Ben Vorlich (3160 ft.), with Ben Lomond (3192 ft.), east of the lake, form a most picturesque group, as seen from many points on the Clyde. Ben Lui (3651 ft.), at the sources of the Tay; Ben More (3819 ft.), rising from Loch Dochart; and Ben Lawers (3984 ft.), near Killin, with many other hardly lower hills, belong to a higher, though less conspicuous, range, than Ben Venue (2800 ft.), Ben Ledi (3009 ft.), and Ben Vorlich (3180 ft.), which dominate over the whole valley of the Firth as far even as Edinburgh. In the southern Grampians, east of the Tay, there are few remarkable summits except Mount Battock (2554 ft.), well seen from the plains of Kincardineshire. Beyond this mountain the chain rapidly descends; and where it terminates in the German Ocean is a mere undulating moorland, over which cultivation is fast spreading. The marked elevations now belong rather to a more interior range connected with the gneiss and granite. This series, beginning with the double-peaked Ben Cruachan (3670 ft.), sinks down in the wild moor of Rannoch (1000 ft. high), bounded on the north-west by the beautifully conical Buachaille Etive (2537 ft.), but again rises in Ben Alder and Ben Vollich on Loch Erich. Schiehallien (3533 ft.), celebrated for Maskelyne's experiment, rendered possible by its isolation, is rivalled by the Ben-y-Gloe and other mountains between the Garry and Upper Dee; of which it is enough to name Cairn Gowar (3725 ft.), Ben Uarn More (3589 ft.), Ben Darg (3550 ft.), Cairn Eelar (3356 ft.), and Scarsoch (3402 ft.). North of this is the granite group round the sources of the Dee, including Ben Macdhui (4296 ft.), 110 feet lower than Ben Nevis, Ben Vrochan (3825 ft.), Benna-Buird, Ben Avon (3968 ft.), and Cairn Gorm (4095 ft.). A similar granite group, but separated by the valley of the Dee, attains its greatest elevation in the "dark Loch-na-Gar" (3800 ft.), with its rugged corry and lake, and is connected through Mount Keen (3180 ft.) with the Eastern Grampians, already noticed.

North of these mountains, in Aberdeen and Banff, there are no hills deserving notice from their elevation. Ben-nachie (1440 ft.), on the borders of the high ground, and conspicuous through the whole of Buchan, the Knock Hill on the coast, and Ben Rinnes (2747 ft.) on the Spey, are the best known. West of the Spey, the Monadhliath Mountains are wild, but tame in outline; and we find no marked

Statistics.

¹ See for the history of this change, and the relation of these strata to the central gneiss of Sutherland, which is still under discussion, papers by Sir R. I. Murchison and Professor Nicol in the *Journal of the Geological Society* and *Proceedings of the British Association for 1855*, &c. Also Murchison's *Siluria*, 2d edition, and Nicol's *Geol. Map of Scotland*, in which the red sandstone of the west coast was first distinguished from the Old Red or Devonian.

Statistics.

summits till we reach the Great Glen. This singular line of depression now regulates the direction of the mountain-ridges, though the massive Ben Nevis (4406 ft.), with its dependants, and the rugged quartzite ridges on Loch Leven and Glencoe, form almost isolated groups.

Beyond the Glenmore-na' Albin, or great valley of the Caledonian canal, though a direction parallel to its course still prevails in the ridges, it is more difficult to trace out. It seems to have been obscured by subsequent geological revolutions; and the most marked valleys and depressions run from east to west. South of Loch Aikaig and Arisaig the country, though wild, is not remarkable for elevation; but the region north is a mass of mountains, with scarce an intervening valley, rivalling those of any other part of Scotland. Scuri Ouran, Ben Line, Ben Serian, Ben Attow (4000 ft.), Scuri-na-Cairnan, Mam Sui (3861 ft.), and Scuri-na-Lapich (3772 ft.), are a few among many lofty but almost unknown summits. Scuri-na-Vertach and Scuri Vullin lead us on to Ben Wyvis (3422 ft.), more marked from its proximity to the east coast than for its height or beauty of form. The Durrie More, with Ben Deig (3550 ft.), are the last group worth noting in central Ross. The interior of Sutherland, too, is a flat undulating table-land; the most marked mountains lying towards the eastern and western shores. The quartzite hills on the latter were already noticed; and we shall only name Ben Leod, at the upper end of Loch Shin, Ben Hee (2858 ft.), and Ben Hope (3061 ft.), as an inner range; and Ben Laoghall, south of the Kyle of Tongue, as a singularly picturesque syenitic mass. Ben Clibrig (3157 ft.) is the most noted of the eastern mountains; Ben Blragie, Ben Horn, and others, being conspicuous only from their position on the coast. So, too, the Ord, the Scarabins (2054 ft.), and other hills on the border of Caithness, are prominent chiefly from contrast with the low plains on the north. No eminence of note breaks the monotony of these plains of undulating flagstones, deeply encumbered with arctic drift. The characteristic scenery of Caithness must, however, be sought in the long line of sea-worn cliffs and bold headlands, crowned by the ruined keeps of the northern vikings, whilst the bleak moors and stagnating waters of the interior are fast yielding to the industry of their descendants.

In the western isles there are a few mountains rivalling those on the mainland, and well known from their position. Such are the Paps (North, 2556 ft.), rising from the quartz ridges of Jura; Ben More (3168 ft.), the chief among the dark trap mountains of Mull; Ben More (2130 ft.), in Rum; the jagged and gloomy Cuchullins, in Skye, with the regular conical Red Hills in the same vicinity, and Suid Thum (2000 ft.); the fractured Storr (2341 ft.); and many more in the north of that island. In the outer Hebrides, Mount Heckla (2940 ft.) in South Uist, and some mountains in Harris Forest, are alone noticeable; the greater part of Lewis being a mere table-land of mingled moor and lochs.

The most important river in this division is the Tay, draining the southern declivities of the Grampians, but already noticed. The Dee, 70 miles long, on the north side of this chain, is a marked contrast to the Tay, in its direct course and its few short tributaries. The Don, Ythan, and Doveran drain the low peninsula of Buchan east of the Spey. This river, 96 miles long, with a basin of 1300 square miles, is the largest flowing to the north sea; and, like its neighbour the Findhorn, is a wild and rapid stream, especially in its upper and mountain portion. North of the Moray Firth there are no important rivers, the Beauly and Conan, each about 40 miles long, and the Oikel, 30 miles long, being the largest on the east coast; the Thurso river and the Naver, on the north. On the west coast, the Lochy, draining the Great Glen, with its main branch, the Spean, alone deserve mention.

One of the marked features of this region is the number

Statistics.

and picturesque features of its lakes. Foremost among them is Loch Lomond, about 20 miles long, and 5 miles broad at the lower end, but narrowing above Luss to a mile or less. In the north, its depth exceeds 100 fathoms; but it is shallower in the south, where its surface is studded with numerous richly-wooded islands. Loch Katterin and Loch Achray are well known from the "Lady of the Lake," though scarce distinguished from many yet unsung. Loch Awe, 25 miles long, chiefly known for the beauty of its northern extremity, but more remarkable for the deep transverse gorge through which its waters flow to Loch Etive; and Loch Tay, with its winding wooded shores, are the largest lakes in this portion of the Highlands. In the wild moor and mountain region to the north-west there are many lakes; as Loch Lydoch, Loch Rannoch, Loch Erich, and Loch Laggan, which, in other situations, would attract more notice. Of the chain of lakes in the valley of the Caledonian Canal, perhaps only separated from each other by detrital matter, Loch Lochy and Loch Ness are the chief; the latter above 20 miles long, and, in part, more than 800 feet deep. It is enough to name Loch Arkaig and Loch Morar, in Inverness; Loch Leuchart and Loch Fannich, in Ross. But Loch Maree, in the latter county, 12 miles long and about 3 wide, though little known, is surpassed by no Scottish lake in picturesque scenery—in the beauty of the labyrinth of wooded islands in the middle, and the magnificence of the rugged mountains at the upper end. Of the innumerable lakes in Western Sutherland, Loch Assynt alone deserves notice for its beauty, though Loch More, Loch Hope, Loch Laoghal, and Loch Naver may be named. Loch Shin, 16 miles long and about a mile broad, with low moory banks, is nearly devoid of beauty; but remarkable as forming, with Lochs Grian, Merkland, More, and Stack, a chain of lakes from the Laxford to the Dornoch Firth, rivalling those of the Glenmore in number, continuity, and slight elevation above the sea-level.

The most marked and characteristic feature of this northern region is, however, the number and extent of its sea-lochs or firths (*fjords* of the Norsemen). Of these the Moray Firth is the most extensive on the east coast; but its interior, including the Beauly Firth, is shallow and encumbered with banks of mud and sand. Its shores, however, are rich and fertile; and the scenery, with the fine mountain outlines in the back-ground, highly beautiful. Cromarty Firth, to the north, even exceeds it in the richness and cultivation of its shores, and the beauty of its more distant landscapes, while as a harbour of refuge it scarcely can be surpassed. The bold headlands of the Sutors mark the entrance in the darkest night, and within there is depth of water and room sufficient for the largest of fleets. The Dornoch Firth is, again, encumbered with shoals in the upper part; and the Fleet, even far below the Mound, almost changed into marshland. On the north coast, Loch Eriboll is the chief indentation, with good anchorage, though open to the north. Rounding Cape Wrath, we find Loch Laxford, still meriting its Norse name from the abundance of its salmon; Badcoul Bay, with innumerable picturesque islands, like a half-submerged portion of the mainland; and the Kyle Sku, with its deep lonely arms, still a favourite resort of the herring. Farther south are the great inlets of the two Lochs Broom, with innumerable islets at their mouth, and deep and safe anchorage within. Loch Greinord is a wide exposed bay, with wild and rocky shores. Loch Ewe, a capacious and safe harbour, less used, however, than the more open Gairloch. Loch Torridon is one of the most magnificent of these Highland lochs, but almost unvisited and thinly peopled since the decline of the western herring fishery. It is divided into three spacious basins; the two interior ones with narrow entrances, and shut in by lofty mountains. Loch Carron, with Loch

Statistics.

Kishorn branching from it on the north, is again a very deep inlet, with more than usual population and cultivation on its shores. Loch Alsh, separating Skye from the mainland, is a safe harbour, with a double opening through the two Kyles; whilst Loch Duich, its southern arm, is celebrated for romantic beauty even on this coast. Loch Hourn is another deep inlet, narrow, rocky, and adorned with natural wood in the upper part, but almost unvisited; and, like the wider but less picturesque Loch Nevis, formerly a great resort of the herring. Loch Sunart, a splendid inlet, 30 miles deep, leads only to the Strontian mines, but, it is said, still shows on its shores some remnants of the old Caledonian oak-forests. Loch Linnhe surpasses in extent and utility any of the western lochs yet named. Its branches, Loch Eil, Loch Leven, Loch Creran, and Loch Etive, are themselves noble bays; and the latter remarkable for the rich beauty of its lower reaches and the rugged grandeur of its upper half, below the granite summits of Cruachan. Among the many lochs between this and Cantyre we need only mention Loch Craignish for the beauty of its wooded islets, and Loch Tarbert, almost separating that peninsula from the mainland. The Firth of Clyde is the last and noblest of these remarkable inlets. Next to the river itself, Loch Fyne, 40 miles long, and still a favourite resort of the herring, and Loch Long, are the more important of its many branches.

Climate.

The climate of Scotland is remarkably equable throughout the year, as the heats of summer and the colds of winter are alike mitigated by winds from the adjacent seas. The mean temperature of the year is about 47°, and the thermometer rarely rises above 80° in summer, and still more rarely does it sink to zero in winter. Such an intense cold as this only occurs once or twice in the course of twenty years in land-locked inland situations, where radiation takes place freely. The thermometer never sinks below 20°, when the wind is blowing with much strength; and it is seldom that it snows when much below 32°. Owing to the physical features of the country, the elements of climate over its surface vary very considerably. The western counties, at equal elevations, have a higher mean temperature than the eastern. This is chiefly due, however, to the higher temperature during the winter in the west, and to the more cloudy state of the sky, which hinders terrestrial radiation. On the other hand, this cloudy state of the sky intercepts the rays of the sun during summer, which renders the heats more moderate, and the climate less suited for the ripening of fruit and grain. This state of things will be rendered more apparent by comparing the mean maximum and minimum temperatures at Rothesay, in Bute, and at Dunino, in Fife:—

Districts.	SPRING.		SUMMER.		AUTUMN.		WINTER.	
	Mean max. temp.	Mean min. temp.	Mean max. temp.	Mean min. temp.	Mean max. temp.	Mean min. temp.	Mean max. temp.	Mean min. temp.
Rothesay.....	52.30	41.0	64.35	51.68	52.97	44.17	42.76	36.54
Dunino	50.30	36.8	64.79	49.53	54.22	41.70	39.62	32.02

The relative intensity of solar and terrestrial radiation is pretty well brought out in these figures, when it is remembered that Dunino is about 300 feet above the level of the sea, and situated in an open and unsheltered district. So, also, the range of the thermometer being greater in the east, it follows that the evaporative or drying powers of the air is greater—a fact well known from other considerations. Besides this, much more rain falls on the west coast, in consequence of the moisture which the south-west winds bring from the ocean.

The prevailing winds in Scotland are from a westerly quarter. Observations show that the wind, on an average, blows from between the south-west and north-west points of the compass more than two-thirds of the whole year.

Statistics.

The wind never remains long either due south or due west. During the westerly gales the wind usually begins to blow from the south-east or south-west, and veers round to west and north-west. These winds, in passing over the hills, let fall a great deal of rain, which renders the climate in these districts exceedingly moist. Nearly a hundred inches of rain fall annually in some of the mountainous parts; whereas, along the southern shores of the Firth of Forth, the annual fall is considerably under 30 inches. In Rothesay, the amount is about 40 inches yearly; while at Musselburgh it is only 24 inches. So long as the south-west winds continue to blow, in winter, the temperature remains high, and the pastures continue green. When the wind goes round to the north, in winter, the temperature is lowered and frost sets in; and continues until it goes round again to the south-west. During rainy periods the winds usually blow from an easterly quarter, and the barometer falls considerably. The rainy east winds, with low barometer, however, have invariably an upper current from the south-west, which brings the moisture to maintain the rains. In the latter part of spring and beginning of summer, east winds often prevail, and have somewhat of a periodical character. They are then usually cold and dry, and accompanied with considerable atmospheric pressure.

Botany.

The flora of Great Britain has been divided geographically by H. C. Watson, into—1. Agrarian, including those plants which are found within the limits of *Pteris aquilina* or the common bracken, the elevation or climate of which would not forbid successful corn cultivation. In the Highlands the region may be said to extend as high, at least, as 1200 feet. 2. Arctic, including the plants above these limits, the region being characterized by the absence of corn cultivation. The agrarian region has been subdivided into three climatic zones. 1. Super-agrarian, characterized by the presence of *Clematis vitalba* or traveller's joy, *Rubra peregrina* or wild madder, and *Cyperus longus* or large galingale. 2. Mid-agrarian, in which *Rhamnus catharticus* or buckthorn occurs without *Clematis*. 3. Super-agrarian, characterized by the presence of *Pteris aquilina* or bracken, without *Rhamnus*. The Arctic region has also been subdivided into three zones—1. Super-arctic, in which *Erica tetralix* or cross-leaved heath, occurs without *Pteris*. 2. Mid-arctic, in which *Calluna vulgaris* or common heather is seen without *Erica*. 3. Super-arctic, indicated by the presence of *Salix herbacea* or the dwarf willow, without *Calluna*.

In Scotland, the super- and mid-agrarian zones are not truly represented. We commence with the super-agrarian, and proceed as far as the super-arctic. In the region of the plains, the common weeds and wild-flowers of Britain are seen with ordinary trees, such as the oak and the ash. An upland region succeeds this, in which certain northern forms occur, such as *Trientalis europæa*, *Linnæa borealis*, *Corallorhiza innata*, *Goodyera repens*, *Vaccinium vitis-idaea*, *Arctostaphylos Uva-ursi*, and *Lobelia Dortmanna*. Some trees, such as *Pinus sylvestris* or Scotch fir, *Betula alba* or common birch, and *Pyrus aucuparia* or mountain ash, extend into a sub-alpine region. This region reaches to about 2400 feet, and extends beyond the limit of trees. It is characterized by such plants as *Thalictrum alpinum*, *Arabis petraea*, *Juncus trifidus*, and *Gnaphalium supinum*. Beyond this a true alpine region is seen, containing such plants as *Draba rupestris*, *Alsine rubella*, *Astragalus alpinus*, *Saxifraga cernua*, and *S. rivularis*, *Erigeron alpinus*, *Veronica alpina*, *Luzula arcuata*, *Luzula spicata*, *Sibbaldia procumbens*, *Gentiana nivalis*, *Azalea procumbens*, and various alpine willows, grasses, ferns, and cryptogamic plants.

There are many plants in Scotland which are restricted to very limited localities. Thus, *Oxytropis campestris* is found only on one rock in Clova, and nowhere else in Bri-

Statistics. tain. The flora of the eastern parts of Scotland differs considerably from that of the western districts.

The best districts in Scotland for alpine species are the Grampian range, more particularly in Clova, Glen Isla, Braemar, the Breadalbane Mountains near Loch Tay, and Loch Lomond—the mountains ranging from 3000 to 4100 feet above the level of the sea. On the summit of Ben-na-Muic Dhu, which is about 100 feet lower than Ben Nevis, we meet with *Luzula arcuata*, *L. spicata*, *Carex rigida*, *Silene acaulis*, *Festuca vivipara*, *Salix herbacea*, *Saxifraga stellaris*, *Juncus trifidus*, *Empetrum nigrum*, *Aira alpina*, *Lycopodium selago*, and some mosses and lichens. Close to the summit of Ben Lawers, *Saxifraga cernua* and *Draba rupestris* occur.

The number of flowering plants and ferns in Scotland amounts to about 1200. They belong to the following types, as given by Watson:—1. British type, including species commonly distributed over Great Britain, such as the alder, hazel, dog-rose, daisy, heather, chickweed, dandelion, nettle, male fern. 2. Scottish type, comprising such species as the globe-flower, crowberry, *Trientalis europæa*, *Primula farinosa*, *Haloscium scoticum*, and *Mertensia maritima*. To this type are referred some very local plants, as *Arenaria norvegica*, *Primula scotica*, and *Ajuga pyramidalis*. 3. Highland type, seen in the plants of the Scottish Highlands, as already noticed. 4. Atlantic type, species chiefly confined to the western district of Scotland, as *Sinapis Monensis*, *Cotyledon Umbilicus*, and *Euphorbia portlandica*. 5. Local type, such as *Eriocaulon septangulare*, found in the Isle of Skye.

Zoology.

The animal kingdom of Scotland differs little from that of England, there being comparatively few species of animals that are not common to both countries. Several of the wild

Statistics. animals that were common in Scotland, even within the historic period, as the bear, wolf, and beaver, have become extinct. In 1057 a Gordon, for his valour in killing a bear, was authorized to carry three bears' heads upon his banner; and so late as 1680 the last wolf in Scotland is said to have been killed by Sir Ewen Cameron of Lochiel. Of the native wild cattle (*Bos urus*) there are in Scotland now only a few preserved in the Duke of Hamilton's park, near Hamilton. Of land quadrupeds there are only about 37 species indigenous to Scotland, among which are the red, fallow, and roe deer, the hare, rabbit, fox, badger, otter, wild-cat, weasel, and hedgehog. Some of these exist in great numbers, but others are becoming scarce. The birds of Scotland number about 270 species, about equally divided between land and water birds. Aquatic birds in great numbers frequent the coast; while, inland, the pheasant, ptarmigan, black-cock, grouse, and partridge abound. The golden eagle and other birds of prey are found in the lofty rocky districts. Attempts have recently been made by the Marquis of Breadalbane and others to re-introduce the capercaillie, or cock of the wood, which was formerly very common in the country, but which appears to have been exterminated about 1760. In the order of reptiles Scotland is fortunately very deficient. The coasts and rivers abound in fish of various kinds. Whales are occasionally seen on the coast, but they were formerly much more common than at present. Shell-fish are plentiful and in great variety. In several of the rivers a species of mussel occurs in which are sometimes found pearls of considerable size.

As regards the agriculture of Scotland, our space only admits of our giving the merest outline of it, in the form of a few remarks on the statistics collected by the Highland and Agricultural Society of Scotland, and given below.

Table of Acreage of principal Crops (1857).

COUNTIES.	Number of Occupants.	Total Acreage under a Rotation of Crops.	Wheat	Barley.	Oats.	Rye.	Bere.	Beans.	Pease.	Vetches or Tares.	Turnips.	Potatoes.	Summer Fallow.	Grass and Hay under Rotation.

Scotland having a humid atmosphere, the greater part of its surface is better suited for the growth of grass and green crops than for wheat, which only comes to perfection in situations of no great height; indeed, an elevation of a few feet is often attended with striking effects on vegetation. Its rocks present the geologist with a well developed series of formations, from the primitive granite to the coal measures, over which vast beds of drift occur. These have produced a great variety of soils, and led to great differences in the systems of management.

In the rich and level plains, such as the Lothians and Stirlingshire, all the cereals, as well as beans, come to great perfection. In these and similar districts where the climate is dry, the land appears to be worth more in crop than under pasture. The following rotation is most common:—1, oats; 2, beans or potatoes; 3, wheat; 4, turnips; 5, wheat or barley; 6, grass. This system, it will be observed, does not admit of many cattle or sheep being reared, as the extent of land under grass is small, and few stock can thus be kept in summer, after supplying the working horses with grass and hay. The turnip crop renders food for stock much more plentiful in winter, and hence the cattle and sheep reared in the pastoral districts find their way to these arable districts in autumn. The whole system of cultivation in them is generally of a very perfect character. The grain is usually sown by the drill, and the crop thrashed and much of it reaped by machinery. Guano and other light manures are liberally applied to the crops.

In Aberdeenshire and other counties, more especially in the higher districts, a different system prevails. There

the soil and climate being more genial to the growth of grass, the land lies longer in pasture. The rotation is also a six course—1, oats; 2, turnips; 3, oats, barley, or bere; 4, grass; 5, grass; 6, grass. This rotation is more economical in manure and labour, but requires a considerable capital for the rearing and feeding of stock. There is no finer class of animals sent to the London market than the Aberdeen polled stock, or the other native breeds crossed with the shorthorn. This being the best grazing district in Scotland, cattle are usually preferred to sheep. Rearing and feeding of cattle are carried on, as the most profitable way of consuming the grass and green crops.

On the steeper lands that have been brought under cultivation along the flanks of the Lammermuir, Cheviot, and other hills, arable farming and the rearing of sheep are combined. Such land is less suited, from its hilly nature, to the breeding of cattle. Leicester tups are put to the Cheviot ewes in November, and a cross is obtained, highly esteemed for its early maturity and fattening qualities. This description of stock is always in great request with the farmers in the more purely arable districts, where it is not found so suitable to breed sheep in any great numbers, owing to the deficiency of grass-lands. These sheep being fed on turnips throughout the winter, and frequently obtaining an allowance of cake or corn, are ready for the butcher in the end of May or beginning of June.

Berwickshire presents us with a good specimen of a well-formed system of farming. The soil in general is of medium quality, and the farms are large. The five course rotation, of—1, oats; 2, turnip; 3, barley or wheat; 4,

Statistics. grass; 5, grass—is, as a whole, more regularly followed than in any other county in Scotland. Thus, by the statistics, it is seen that the oat crop occupies fully one-fifth of the whole acreage under rotation; turnips, one-fifth; wheat and barley together, make up another fifth; grass, nearly two-fifths. For various reasons, the extent of land under potatoes does not exceed one-thirtieth of the extent of land under turnips. The bean crop occupies only a little more.

On the other hand, where there are larger portions of rich lands, as in the counties of Haddington, Stirling, Fife, and Perth, the proportional extent of beans and potatoes is increased. These two crops being also good preparatives for wheat, its average will be found to increase in like proportions. On the other hand, it is singular enough that the extent in turnips is less in the western counties than in the eastern. Banff, with less than half the extent of land under rotation of Ayrshire, has a greater extent under turnips. In all the western counties, the potato, on medium quality of land, occupies a larger breadth than in the eastern. In the west, the farms are usually smaller, and the dairy furnishes more employment for the tenants and their families. The necessity for raising turnips, which is an expensive crop, is not so much felt, as in the corn districts where cattle and sheep are fattened. The larger proportion, too, of wheat and barley grown in the east enables the cultivators to grow a greater extent of turnips.

The larger part of the surface of Scotland, being mountainous, is really capable of comparatively little improvement. Heaths and natural grasses occupy the soil, and yield a scanty herbage for sheep or cattle. There the art of man has been in a great measure confined to the improving of the breeds of stock, and in distributing the most suitable over the different kinds of pasture-grounds. Much skill has been displayed in this matter, with valuable results. In the wildest regions of the West Highlands, as well as in the highest and most stormy ground in the north, the black-faced Highland sheep is found to be best suited to withstand the deteriorating

influences of the climate. The Cheviot sheep is only slightly inferior to the black-faced sheep for the mountains, and has already been largely introduced into the North Highlands. Both these hardy animals usually receive no other food than what they find on the hills, and are often subjected to great privations during deep snows in winter. Wide as these hilly and pastoral districts stretch, they are no larger than is required to breed animals for the consumption of turnips in the arable districts.

The rapid progress of Scottish agriculture is, no doubt, to be greatly attributed to granting of leases of nineteen years by proprietors. This period generally enables the tenants to reap the rewards of the improvements made on the farms they occupy. In some cases, the restrictions in leases may have had the effect of cramping the tenants' energies; but, as a rule, the system has wrought admirably. Since the middle of the last century the farms have been greatly consolidated in most of the counties. By the greater economy of labour that the large-farm system introduced, the strictly rural population has become less numerous. The higher wages in the towns have attracted large numbers. This revolution, brought about by the introduction of better cultivation, has not been without its disadvantages in a moral point of view. For it can hardly be disguised that the social condition of the agricultural labourers has not kept pace with the improvement in the art. A reform in this condition of things is being gradually brought about, as is apparent from the better class of cottages that is in course of being erected over the land.

Population. The population of Scotland, at the time of the Union in 1707, is not supposed to have exceeded 1,050,000. It was first ascertained, with tolerable precision, in 1755, from returns furnished by the clergy to Dr Webster, the omissions and deficiencies being supplied from the most approved data; and was found to be 1,265,380. The first government census was taken in 1801, and the following table gives the population, and rate of increase in each county, since that time:—

COUNTIES	Area in Square Miles.	Pop. 1801	In-crease per Cent.	1811.	In-crease per Cent.	1821.	In-crease per Cent.	1831.	In-crease per Cent.	1841.	In-crease per Cent.	1851.	Increase per Cent. from 1801 to 1851.

Statistics.

The rate of increase for the whole of Scotland during fifty years, from 1801, is 79 per cent., whereas for England and Wales it is as high as 101 per cent. The county in which the greatest increase has taken place is Lanark, where it reaches 258 per cent. The neighbouring counties of Ayr and Dumbarton follow, having 125 and 117 respectively. Edinburgh and Clackmannan have each 111, and Renfrew 105. On the other hand, the smallest increase has taken place in Argyle and Perth, having each only 10 per cent.; Sutherland only 12; Nairn, 19; Berwick, 20; Haddington, 21; Peebles, 23; Kincardine, 31; Inverness, Kinross, and Orkney and Shetland, 33; Elgin, 40; Bute, 41; Dumfries, 43; Banff, 45; and Ross and Cromarty, 47. This small increase has, in too many instances, arisen from the system of "clearings," by which the cottar or small farmer is driven from his home to seek refuge in our large towns, or in a foreign country, in order to make room for sheep and deer. The population of Scotland in 1858 is estimated at 3,093,370.

The progress of the population in the seven largest towns of Scotland during the half century preceding 1851, will be seen from the following table:—

Name.	1801.	1811.	1821.	1831.	1841.	1851.
Edinburgh } with Leith	81,404	101,492	136,351	159,732	164,174	191,221
Glasgow.	77,058	103,224	140,432	193,030	261,004	329,097
Aberdeen	26,992	34,640	43,821	56,681	63,288	71,973
Dundee	27,396	31,058	32,126	48,026	64,629	78,931
Paisley	25,058	29,461	38,102	46,222	48,263	47,952
Greenock	17,190	18,750	21,719	27,082	36,169	36,689
Perth	16,388	16,564	18,197	19,238	20,407	23,835

In 1851, there were 1,375,479 males, and 1,513,263 females in Scotland, being an excess of 137,784 of the latter over the former. This excess is considerably greater in Scotland than in England; there being in England and Wales 102 females to 100 males; and in Scotland, 107 females to 100 males. This disparity between the two countries is greater after the age of 20; there being in England and Wales 115 females to 100 males, and in Scotland 130 females to 100 males, of the age of 20 and upwards. Under the age of 20 the number of males exceeds that of females, and that to a greater extent in Scotland than in England. The excess of females at the ages above 20 is ascribed, partly to the fact that the mortality of females is less than that of males, and also to the circumstance that so many young Scotchmen cross the Tweed, or emigrate to foreign countries before marriage. Under the age of 20 there are only 97,595 females to 100,000 males; between the ages of 20 and 40 there are 111,638; between 40 and 60, 117,016; between 60 and 80, 134,649; and above 80, 158,629 females to 100,000 males.

The proportion of those who enter the married state in Scotland is much smaller than in England. Of males, of the age of 20 and upwards, 30 per cent. in England and 35 per cent. in Scotland were bachelors; and of females of the same age, 28 per cent. in England and 36 per cent. in Scotland were spinsters. In England, too, the proportion of early marriages is greater than in Scotland. Of young men, from 20 to 25 years of age, 20 per cent. in England and 16 per cent. in Scotland were married; while of women, of the same age, 31 per cent. in England, and only 25 per cent. in Scotland, were married. Of the male population of Scotland, of 20 years of age and upwards, 35·3 per cent. were bachelors, 58 husbands, and 6·6 widowers: of females, of the same age, 36·1 were spinsters, 49·1 wives, and 14·8 widows. The total number of husbands was 410,349; of wives, 422,296. There are proportionally fewer widowers, and more widows, in Scotland than in England; which, perhaps, may be accounted for by widowers marrying again

more, and widows less, frequently in Scotland than in England.

The number of blind, as ascertained by the census of 1851, was 3010, or 1 to every 960 of the population; of deaf and dumb, 2155, or 1 to every 1340 of the population. There were also inmates of prisons, 2993; of workhouses, 5438; of lunatic asylums, 2353; and of hospitals for the sick, 1192.

The following table gives the number and proportion, to the estimated population, of births, deaths, and marriages in Scotland, during the years 1855–58:—

Year.	Births.			Deaths.			Marriages.		
	Number.	Per cent.	Ratio.	Number.	Per cent.	Ratio.	Number.	Per cent.	Ratio.
1855	93,599	3·11	1 in 32	62,249	2·07	1 in 48	19,690	0·65	1 in 152
1856	101,748	3·35	1 in 29	58,456	1·92	1 in 52	20,487	0·67	1 in 148
1857	103,629	3·38	1 in 29	61,925	2·02	1 in 49	21,314	0·69	1 in 143
1858	104,195	3·37	1 in 29	63,532	2·05	1 in 48	19,603	0·63	1 in 157

The proportion of births, deaths, and marriages is lowest in the rural districts, higher in the small towns, and highest in the great towns. Thus, in 1858, in the eight principal towns of Scotland, the proportion of marriages was 77 to every 10,000 persons of the estimated population; in the smaller towns the proportion was 66; while in the rural districts the proportion was only 53. Of births, in the same way, the proportion in the eight principal towns was 369 to every 10,000 persons; in the smaller towns, 358; while in the country districts it was only 307. We see in this a wise provision of nature, that as the consumpt of life is greater in the towns, and this somewhat in proportion to their size, so, to secure a continuance of the species in these less healthy localities, a greater number of marriages and births occur there.

Of the 104,195 births in 1858, 53,826 were males, and 50,369 females, being in the proportion of 100 males to every 93½ females; a proportion of males higher than in any of the three previous years. The number of illegitimate births was 9256, giving a proportion of 8·8 per cent. of the births as illegitimate, or 1 illegitimate in every 11·2 births. This is a higher proportion by rather more than 2 per cent. than in England. In the eight principal towns of Scotland, 8·4 per cent. of the births were illegitimate; in the smaller towns, 8·6 per cent.; and in the rural districts, 9·3. Of the counties, Banff exhibits the highest proportion of illegitimate births, being no less than 16·1 per cent.; next follow Aberdeen, 14·9; Dumfries, 14·4; Kirkcudbright, 13·8; Kincardine, 13·1; while in the great manufacturing and mining county of Lanark, the proportion was only 7·1 per cent., and in Renfrew only 6·8.

The mean annual mortality in Scotland for the past four years has been at the rate of 203 deaths in every 10,000 persons; that of England, for the same period, 219 deaths in the same population. In the eight largest towns there were, in 1858, 265 deaths to every 10,000 of the population; in the smaller towns, 217; and in the rural districts only 164. Of the 63,532 persons who died during 1858, 31,660 were males, and 31,872 females; from which it appears that the males die in the proportion of 241 in every 10,000 of the estimated male population, and the females in the proportion of only 196 in a like number of females.

The Reformation in Scotland began at an early period, but it was not until 1560 that Popery was abolished by act of Parliament, and the Protestant religion established in its stead. The history and constitution of the prevailing sects in Scotland have already been so fully treated of in the article PRESBYTERIANISM, that it is unnecessary to do more here than give some statistics of the different bodies, founded on the census of 1851. The three prevailing sects are the Established, the Free, and the United Pres-

Statistics.

Statistics. byterian Churches. The proportion of adherents belonging to each are estimated as follows:—

Established Church.....	34 per cent.
Free Church	32 „ „
United Presbyterian Church	18 „ „
All other Churches	16 „ „

It is to be borne in mind, however, that a number of the clergy refused returns of the attendance at their places of worship, and the deficiencies were made up by assigning to such congregations the average of the attendance at the other places of worship of the same sect. There were 431 churches from which no returns were obtained, of which 279 belonged to the Established Church, 65 to the Free Church, and 38 to the United Presbyterian. The refusals, doubtless, in most cases, arose from the smallness of the congregations, and to allow for such an average of the number attending the other places of worship of the same sect, is manifestly to place them in too favourable a light. The great majority of these refusals being in the Established Church, the probability therefore is, that the number of her adherents is rather overestimated than otherwise. The Established Church may hence be said to possess only one-third of the worshippers of Scotland, and to barely exceed the Free Church. Taking the different counties, and including only the places of worship from which returns were made, we find that the Established Church had the majority of worshippers in 14 counties—Ayr, Banff, Berwick, Dumfries, Dumfries, Fife, Forfar, Haddington, Kincardine, Kirkcudbright, Orkney and Shetland, Peebles, Stirling, and Wigton; the Free Church in 12 counties—Aberdeen, Argyll, Bute, Caithness, Edinburgh, Elgin, Inverness, Nairn, Perth, Renfrew, Ross and Cromarty, and Sutherland; and the United Presbyterian Church in 6 counties—Clackmannan, Kinross, Lanark, Linlithgow, Roxburgh, and Selkirk. The following table gives the number of places of worship and sittings, and the attendance at each of the three diets on Sunday, 30th March 1851:—

Denominations.	Places of Worship.	Sittings.	Attendance.		
			Morning.	Afternoon.	Evening.
Established	1183	767,080	351,454	184,192	30,763
Free	889	495,335	292,308	198,583	64,811
United Pres- byterian ..	465	288,100	159,191	146,411	30,810
Other Deno- minations. }	858	284,282	140,998	90,677	62,490
Total.....	3395	1,834,805	943,951	619,863	188,874

At the morning service little more than one half of the sittings were occupied, and in the afternoon little more than one-third. The proportion of unoccupied sittings is largest in the Established Church, and smallest in the Free Church, although even the latter cannot boast of having her pews much more than half filled. The proportion of attendants to population is less than a third in the forenoon, and rather more than a fifth in the afternoon. There are sittings provided for $63\frac{1}{2}$ per cent. of the entire population, a number considerably greater than can possibly be used. Were all the population capable of attending public worship to do so, it is estimated that not more than 58 per cent. would be required, so that the accommodation is $5\frac{1}{2}$ per cent. above what can possibly be required.

From 2914 places of worship returns more or less complete were obtained. Of these 2694 were separate buildings, and 220 were not separate buildings. The following table gives the number of places of worship belonging to other sects in Scotland, with their sittings and attendance on the 30th of March 1851:—

The subject of education engaged the attention of the Scottish Parliament as early as the year 1494. At that time the schools were generally attached to some religious establishment. After the Reformation the Protestant Church zealously took up the cause of education, and many acts of the General Assembly were passed in favour of it. The government, however, cannot be said to have interfered till 1616, when the privy council enacted, "That in every parish of this kingdom, where convenient means may be had for entertaining a school, a school shall be established, and a fit person appointed to teach the same, upon the expense of the parishioners, according to the quality and quantity of the parish;" but it was not till seventeen years thereafter that this act of council was ratified by Parliament. The then disturbed state of the country prevented the act from becoming operative; and it was not till some time after the Revolution, namely in 1695, that the celebrated statute of William and Mary was passed, which forms the foundation of the present parochial system. It enacts, "That there be a school founded and a schoolmaster appointed in every parish (not already provided) by advice of the presbyteries; and to this purpose that the heritors do in every congregation meet among themselves and provide a commodious house for a school, and modify a stipend to the schoolmaster, which shall not be under 100 merks (L.5, 11s. 1½d.), nor above 200 merks (L.11, 2s. 2½d.), to be paid yearly, at two terms." The provisions of this act were immediately carried into effect in most parishes, and now the system is in universal operation throughout Scotland. The schoolmasters' salary continued as fixed by the statute of William and Mary till 1803, when it was enacted, "That from and after the term of Martinmas next, the

Statistics. salary of each parochial schoolmaster, in every parish in Scotland, shall not be under the sum of 300 merks Scots (L.16, 13s. 4d.), *per annum*, nor above the sum of 400 merks (L.22, 4s. 5½d.), except in the cases hereinafter-mentioned." The exceptions have regard to cases where it is necessary to have two or more parochial schoolmasters in one parish. The heritors have also to provide a commodious house for a school, a dwelling-house of at least two apartments, and at least a quarter of an acre Scots of ground for a garden. The act provided for the augmentation of the salary at the end of every twenty-five years, according to the value of the chalders of oatmeal, which, at the date of the passing of the act, was estimated at 200 merks Scots. In 1828, therefore, the salary of each parochial schoolmaster was raised upwards of a third, the *maximum* being L.34, 4s. 4½d., and the *minimum* L.25, 13s. 3½d. The inadequacy of this provision has of late been universally admitted. When, in 1853, a new average fell to be introduced, an education bill providing, among other things, for raising the status of the schoolmasters was expected speedily to become law, and the old rates were therefore continued from year to year in expectation of that taking place, till 1857, when an act was passed providing for fixing the average, on or before 1st July 1859, in terms of the act passed in 1803. Besides the statutory allowance, schoolmasters receive fees from their pupils, according to a scale fixed by the minister and heritors. The fees are generally very low, sometimes not more than 1s. or 1s. 6d. per quarter for English; and the schoolmaster is further bound to teach gratuitously "such poor children of the parish as shall be recommended by the heritors and minister at any parochial meeting." Frequently the parish schoolmaster adds to his salary by acting as session-clerk, precentor, &c.; and in many cases benevolent individuals have left sums for the better endowment of parish schools. The late James Dick, Esq., of London, bequeathed the sum of L.118,787 to augment the salaries of parochial schoolmasters in the counties of Aberdeen, Banff, and Moray. The choice of the schoolmaster is vested in the minister and heritors, and the person elected must be found qualified by the presbytery as to morals, religion, and literature.

Besides the parish schools, there are a number of other elementary schools supported by Christian bodies or societies. As early as 1701 a few private individuals in Edinburgh formed themselves into an association, under the title of "The Society in Scotland for Propagating Christian Knowledge," and established a number of schools throughout the country, chiefly in the Highlands and islands. The number of schools so established and maintained at present (1859) is 231, at an annual expenditure of upwards of L.3000. In 1824, the General Assembly appointed a committee to inquire into the state of education, and take steps for its improvement. This led to the establishment of a number of new schools; and these at present amount to 181, with 20,525 scholars. On the Disruption, the Free Church established a number of schools in connection with their places of worship. The number of these in 1859 was 617 (*viz.*, 455 congregational; 127 side; 28 missionary; 5 grammar; and 2 normal schools), with 647 teachers, and 62,205 scholars. There are also, throughout Scotland, a large number of private schools supported entirely by the school fees. In the cities and larger towns there are grammar or high schools and academies for communicating the higher branches of instruction; and there are 5 normal schools for the training of teachers, 2 connected with the Established Church, 2 with the Free Church, and 1 with the Episcopal Church. There are also the universities of Edinburgh, Glasgow, Aberdeen, and St Andrews, an account of which will be found in the article UNIVERSITIES.

Since 1839 the Privy Council has annually granted certain sums to aid in the establishment and support of schools,

under certain conditions. The following table shows the number of school-houses built, enlarged, or improved, with aid from such grants, the amount so granted, the amount subscribed by the promoters, the total amount expended, and the number of children for whom accommodation has thus been provided from 1839 to 31st December 1858:—

Denominations.	School-houses.	Amount of Grants.	Amount Subscribed.	Total Expended.	Accommodation provided.
		L.	L.	L.	
Established Church schools	237	36,649	75,325	111,974	23,361
Free Church, and others not connected with the Establishment	224	24,473	49,490	73,963	19,747
Episcopal Church schs.	9	2,577	4,554	7,131	1,247
Total... ..	470	63,699	129,369	193,068	44,355

The whole expenditure for Scotland from the beginning of the grants in 1839 to the end of the year 1858 was, on schools connected with the Established Church, L.232,961; on schools connected with the Free Church, L.185,877; and on schools connected with the Episcopal Church, L.18,903. The expenditure for the year 1858 was, on schools connected with the Established Church, L.46,774, (being an increase on the previous year of L.9949); on schools connected with the Free Church, L.31,609, (being an increase on the previous year of L.3194); on schools connected with the Episcopal Church, L.5536, (being an increase on the previous year of L.661).

According to the census of 1851, there were then in Scotland, in all, 5242 day schools, of which 3349 were public, and 1893 private day schools. The number of scholars attending the former was 280,045 (161,754 males, and 118,291 females); attending the latter, 88,472 (43,594 males, and 44,878 females). The total, 368,517, gives a proportion to the population of 12.76 per cent., or one scholar to every 7.84 inhabitants. Making a fair allowance for deficient returns, it seems probable that about 14 per cent., or one in every seven, of the people of Scotland are at school. As compared with the other side of the Tweed, this is not an unfavourable result, the total number of day-scholars at school in England and Wales being 2,144,378, out of a population of 17,927,609, or in the proportion of one to every 8½ of the whole population. The number returned as scholars in the householders' schedule, under the head occupation, was 426,566. The public day schools are arranged by the compilers of the census in four groups, according to the sources from which they are maintained. Class 1 is designed to represent the number of schools which depend for their support upon the public taxes, whether national or local, and in this class all parochial and burgh schools are included. Class 2 was intended to show the number of schools sustained *chiefly* by *permanent endowment*, but it was found that, in the returns, the word "endowment" was used to signify not merely funds assigned in perpetuity for education, but also the aid afforded by the educational societies and the contributions of the heritors; so that this class, in reality, represents the number (exclusive of parochial and burgh schools), which derive the principal portion of their sustenance from "endowments," as understood by the parties who made the return. Class 3 shows the action of religious bodies in the matter of education, so far as they act denominationally; while class 4 displays the influence of general philanthropy, apart from any sectarian organization. The following table exhibits the results according to this mode of classification.

Total Public Day Schools	3349	280,045	161,754	118,291

Returns of income for the year 1850 were received from 2511 public day schools, having 210,363 scholars. The total income was L.173,436, of which L.62,089 were permanent endowments, L.21,824 voluntary contributions; L.6643 grants from government; L.64,471 payments by scholars; L.18,409 other sources. Of 1662 endowed schools, 59 had endowments of less than L.5; 140 of L.5 and less than L.10; 381 of L.10 and less than L.20; 922 of L.20 and less than L.50; 33 of L.50 and less than L.100; 10 of L.100 and less than L.200; 9 of L.200 and less than L.500; 2 of L.500 and less than L.1000; 2 of L.1000 and less than L.2000; 2 of L.2000 and upwards. The endowments of 102 were not stated.

Returns were made as to the remuneration of 1695 masters, and 295 mistresses of public day schools. The total aggregate amount of the remuneration of masters was L.78,393, of which L.41,423 arose from salary, and L.36,970

from school fees. The average remuneration per master was L.46. Of 691 masters in schools of class I., the average remuneration was L.55; of 232 in schools of class II., L.39; of 736 in schools of class III., L.39; and of 136 in schools of class IV., L.45. The number of masters allowed a residence was 1110. The total aggregate amount of remuneration of mistresses was L.6288, of which L.4089 arose from salary, and L.2199 from school fees. The average remuneration per mistress was L.21. The number of mistresses allowed a residence was 137. Information as to teachers was received from 2818 public day schools, having 142,637 male, and 103,813 female scholars. The total number of male teachers was 4821, of whom 2903 were masters, 553 paid monitors and pupil teachers, and 1365 unpaid teachers. The total number of female teachers was 1792, of whom 894 were mistresses, 241 paid monitors and pupil teachers, and 657 unpaid teachers.

Besides the day schools, there were 438 adult evening schools, with 9500 males, and 5571 female scholars. The number of teachers was 629, of whom 526 were males, and 103 females. In 44 of these schools instruction was free. Of 10,327 adult evening scholars, 4386 were artisans; 2397 factory operatives; 561 agricultural labourers; 553 domestic servants; 349 weavers; 348 coal and iron operatives; 287 bleachers; 278 warehousemen; 385 miners; and 166 clerks. There were also found to be 221 mechanics', literary, and similar institutions in the country.

The number of Sunday schools was 3803, with 292,549 scholars (135,435 males, and 157,114 females), being 10.1 per cent. of the population. Of these schools, 1095 belonged to the Established Church; 1243 to the Free Church; and 558 to the United Presbyterian Church. There were 25,411 teachers, of whom 14,181 were males, and 11,230 females; 152 were paid, and 25,259 unpaid.

The following table exhibits the state of crime in Scotland in 1855, 1856, and 1857, as well as in each of the four quinquennial periods immediately preceding:—

	Average of 1836-40	Average of 1841-45	Average of 1846-50	Average of 1851-55	Year 1855	Year 1856	Year 1857

Statistics.

Statistics.

Of the 3169 persons tried in 1857, there were tried by the High Court of Justiciary 99; by the Circuit Court of Justiciary 375; by the sheriff with a jury, 1114; by the sheriff without a jury, 1402; by burgh magistrates, 144; by justices or other courts, 5. The sentences passed in that year were transportation for life, 2; transportation for more than 15 years, 8; transportation for 15 or 14 years, 18; penal servitude for life, 1; penal servitude for more than 15 years, 2; penal servitude for 15 years and above 10 years, 4; penal servitude for 10 years and above 6 years, 24; penal servitude for 6 years and above 4 years, 50; penal servitude for 4 years, 132; penal servitude for 3 years, 17; imprisonment for 3 years and above 2 years, 2; imprisonment for 2 years and above 1 year, 132; imprisonment for 1 year and above 6 months, 326; imprisonment for 6 months and under, 1877; whipping, fine, and discharge, 287.

Occupation.

The total number of males in Scotland in 1851 was 1,375,479, of whom 3352 were Protestant clergymen; 2422 lawyers; 3010 medical men; 2557 law clerks; 1194 druggists; 282 literary writers; 371 artists; 273 architects; 420 civil engineers; 3982 schoolmasters; 1983 land proprietors; 48,071 farmers; 94,899 outdoor agricultural labourers; 45,346 farm-servants (indoor); 8489 domestic servants; 2915 road labourers; 5203 railway labourers; 40,701 labourers (undefined); 8276 gardeners; 1944 gamekeepers; 1903 grooms or jockeys; 19,617 fishermen; 12,189 seamen; 32,971 coal-miners; 7619 iron-miners; 898 lead-miners; 4527 stone-quarriers; 784 slate-quarriers; 1116 limestone-quarriers, or burners; 2017 brickmakers; 12,283 carriers, carters, &c.; 1434 publishers or booksellers; 1019 bookbinders; 3401 printers; 623 engravers; 45,560 engaged in the manufacture of cotton; 32,907 of linen; 9572 of woollen cloth; 2317 of carpets and rugs; 367 of worsted; 1824 of stockings; 1539 of silk; 1265 of paper; 1645 of earthenware; 13,240 of iron; 724 of glass; and 1673 of chemicals; 2762 dyers; 8860 cotton printers; 17,093 blacksmiths; 1549 nailmakers; 1430 boilermakers; 5719 engine, machine, and toolmakers; 1534 brassfounders; 166 wire-workers; 185 gunsmiths; 1894 tinsmiths; 305 copper-smiths; 755 gold and silver smiths; 1526 watchmakers; 657 combmakers; 685 sugar-refiners; 2411 ropemakers; 161 soap-boilers; 393 tallow-chandlers; 1220 curriers; 815 tanners; 453 skimmers; 531 cork-cutters; 530 tobacconists; 9621 grocers; 2937 wine and spirit merchants; 2338 licensed victuallers; 1840 innkeepers; 1152 brewers; 561 maltsters; 4471 millers; 9541 bakers; 1155 confectioners; 4851 butchers; 29,703 shoemakers; 18,492 tailors; 772 hatters; 827 hair-dressers; 1006 builders; 773 bricklayers; 22,332 masons and paviors; 24,066 carpenters and joiners; 2707 slaters; 1793 plasterers; 5545 painters and plumbers; 5528 cabinet-makers and upholsterers; 1185 turners; 4025 coopers; 4729 sawyers; 2020 wheel-wrights; 2249 mill-wrights; 1162 coachmakers; 1642 saddlers; 4395 ship and boat builders; 1256 were in the post-office service; 1173 in the inland revenue; 1019 customs; and 1920 police.

Of the 1,513,263 females, 114,751 were domestic servants; 28,477 indoor farm-servants; 26,151 agricultural labourers (outdoor); 28,902 milliners; 12,971 seamstresses; 1457 staymakers; 2049 schoolmistresses; 1164 governesses; 10,380 washerwomen, laundresses, &c.; 4865 farmers; 4024 grocers; 1082 licensed victuallers; 524 wine and spirit merchants; 52,685 were employed in the manufacture of cotton; 39,579 linen; 5696 woollen cloth; 945 worsted; 4715 stockings; 1059 silk; 2159 paper; 653 straw plait; 3006 shawls; 5602 were cotton printers; and 4361 embroiderers.

The coal and iron mines of Scotland are great sources of wealth, and afford employment to a great number of the population. In 1858 there were 417 coal mines in Scotland, in the counties of Lanark, Ayr, Fife, Clack-

mannan, Haddington, Edinburgh, Linlithgow, Stirling, Dumfriesshire, Dumfries, Perth, &c. These were estimated to employ 32,000 persons, of whom about 27,000 were colliers and drawers, the remainder being overseers, engine-keepers, mechanics, labourers, &c. The total quantity of coal produced in 1854 was 7,448,000 tons; and in 1858, 8,926,249 tons.

Iron is of frequent occurrence in the coal districts, especially in Lanarkshire, where the ores are of the very best quality. The iron trade of that county, and of Scotland generally, has increased with unexampled rapidity. In 1825 there were only 33,540; and in 1830, 37,500 tons of iron produced in Scotland; whereas in 1840 it had risen to 241,000 tons; in 1854 to 796,640; in 1856 to 832,000; and in 1858 to 925,500 tons. The quantity of ore raised in this last mentioned year was 2,312,000 tons, valued at L.750,000. In 1858 there were 32 iron-works in Scotland, with 177 furnaces, of which 132 were in blast. Of these, 13 iron-works, with 97 furnaces, 81 being in blast, were in Lanarkshire; and 9 ironworks, with 50 furnaces, of which 32 in blast, were in Ayrshire.

The number of lead mines in Scotland in 1858 was 9, Lead. of which 1 was in Dumfriesshire (Wanlockhead), producing 870 tons of ore; 1 in Lanarkshire (Lead Hills), 1087 tons; 4 in Kirkcudbrightshire, 235 tons; 1 in Argyleshire, 44 tons; 1 in Perthshire, 54 tons. The total produce of lead ore was 2290 tons, from which 1586 tons of lead were obtained, and 4882 ounces of silver extracted.

The salmon fishery of Scotland has long been very considerable. It is chiefly carried on in the rivers on the east coast,—the Tweed, Forth, Tay, Dee, Don, Findhorn, Spey, Ness, &c. The London market is chiefly supplied with salmon from Scotland. Before the London trade commenced, salmon was so common in the country, that, in some parts, domestic servants used to stipulate that they should not be obliged to dine on it more than three or four times a week. Of late years the value of the river-fisheries has declined considerably, owing, doubtless, in a great measure, to the increased use of stake and bag nets in estuaries and along the coast. See article FISHERIES.

The herring fishery is an important branch of industry, and has long been extensively carried on. Till a recent period large sums were annually expended by government in premiums and bounties to stimulate this branch of industry, but these were finally abolished in 1830, and since that time it has gradually but steadily progressed. In 1830, 329,557 barrels of herring were cured; in 1840, 543,945; and in 1857 (an unfavourable year), 580,813. The total produce of this fishery in Scotland and the Isle of Man in the last of these years was 666,934 barrels, of which 86,121 barrels were sold or disposed of for immediate consumption, and 580,813 cured; 218,992 were branded; 367,160 exported; and assorted after the Dutch mode, and branded accordingly, 178,440 "full," and 283 "matied." The export trade to the Continent is rapidly increasing; and there the Scotch herrings now rival those of any other country. In 1857, 307,275 barrels were exported to the Continent.

The cod and ling fisheries produced in 1857, 157,706 Cod and cwt., and 4393 barrels; of which there were cured dried, ling, 104,668 cwt.; and cured in pickle, 4393 barrels; exported, 34,310 cwt. The quantity caught and not cured was 53,038 cwt.

In 1857 the herring, cod, and ling fisheries in Scotland employed 11,858 boats. (3702 1st class—30 feet keel and upwards; 3607 2d class—18 to 30 feet keel; and 4549 3d class—under 18 feet keel); having an aggregate burden of 82,175 tons. The total number of persons employed was 90,543, of whom 40,724 were fishermen and boys; 2045 coopers; 19,748 gutters, packers, &c.; 28,026 net-makers, venders, &c.; and 1017 fish-curers. The total value of boats, nets, and lines was L.702,715; of which L.85,811

Mines.

Coal.

Statistics. belonged to the Wick district; L. 72,702 to the Banff district; L. 72,640 to the Anstruther district; L. 47,118 to the Peterhead district; L. 41,695 to the Eyemouth district; L. 32,216 to the Inverary district; L. 30,926 to the Leith district; L. 29,407 to the Orkney district; L. 29,588 to the Fraserburgh district; L. 25,545 to the Findhorn district; L. 20,384 to the Rothesay district; L. 26,725 to the Stornoway district; L. 23,557 to the Lybster district; L. 21,060 to the Loch Broom district; and L. 20,344 to the Loch Shiel-dag district. The total value of the boats was L. 265,569; of the nets L. 373,963; and of the lines, L. 63,183.

The prosperity of the fisheries in general has had a very beneficial effect upon the fishermen. Their social condition has improved; their labours are now more largely remunerated; and they have found that diligence, and skill, and enterprise are necessary to success. A great advance has taken place in the size and character of the boats employed; and the number and value of the nets in use by each boat have also greatly increased. This spirit of improvement is also beginning to manifest itself in their towns and villages; their dwelling-houses are being improved, shops of larger size and of superior character are increasing, and roads and other means of communication are being opened up.

**Manufac-
tures.
Linen.** It is only since the union with England that Scotland has attained to any importance in the manufactures. The linen manufacture was the earliest, and was long regarded as the staple branch of industry. At the time of the Union in 1707 it is not supposed to have yielded more than 1,500,000 yards a year. In 1727 a board of trustees was established for the superintendence and encouragement of the linen manufacture; and bounties and premiums were given to encourage its production and exportation. The quantity produced for sale in 1728 was 2,000,000 yards; in 1775, 12,000,000 yards; and in 1822, 36,000,000 yards. The regulations as to the inspection and stamping of the linen intended for exportation, by which the trade was much annoyed, were abolished in 1822, and the bounties ceased in 1830.

Previously to 1791 all the flax used in the manufacture was spun upon the common hand-wheel; but at that time the spinning by machinery began to be introduced, and since then the progress of this manufacture has been rapid. In 1837 the flax factories employed 15,462 hands; in 1850, 28,312; and in 1856, 31,722, of whom 8331 were males and 23,391 females. In 1850 there were 189 factories, with 303,125 spindles, and 2529 power-looms; and in 1856 there were 168 factories, with 278,304 spindles and 4011 power-looms, driven by 6346 horse-power, of which 5529 was steam. The principal seat of the linen manufacture is Dundee, especially of the coarser fabrics,—as sailcloth, sack-ing, sheeting, osnaburgh, &c. In Kirkcaldy, Arbroath, Forfar, Montrose, and Aberdeen this manufacture is also largely carried on. In Dunfermline, and the immediate vicinity, the finer fabrics are chiefly manufactured. The counties where the linen manufacture is chiefly carried on are Forfar, Fife, and Aberdeen; to a less extent, Perth, Lanark, Renfrew, Edinburgh, and Ayr; and to a small extent, Kincardine.

Cotton. The cotton manufacture in Scotland is only of comparatively recent introduction, the first steam-engine for a cotton factory having been constructed so late as 1792. Its principal seats are in the counties of Lanark and Renfrew. Some of the fabrics made at Glasgow and Paisley are of almost unrivalled beauty and fineness. The number of cotton mills in 1837 was 177; all those of considerable size, with only a few exceptions, being situated in Glasgow, or within 20 or 30 miles of it, and all of them without exception being connected with Glasgow houses, or the Glasgow trade, at least so far as the raw material was concerned. In 1850 the number of cotton factories was 168, with 1,683,093 spindles and 23,564 power-looms, employing 36,325 hands. In 1857 there were 152 cotton factories,

with 2,041,129 spindles and 21,624 power-looms, driven by 9971 horse-power, of which 7641 was steam, and employing 34,698 hands, of whom 7609 were males and 27,089 females. The entire cotton manufacture of Scotland may be said to centre in, or be dependent on, Glasgow.

Statistics. The woollen manufacture has never been considerable in Scotland; but it is more generally diffused over the country than either of the other two, being carried on, to a greater or lesser extent, in 24 of the 32 counties; whereas the linen manufacture is carried on only in 9, and the cotton in 10. It was formerly the custom for the occupiers of land to spin the whole of their wool with the hand in their own houses, and to send the yarn to the village weaver to be woven into a species of coarse cloth called *plaiding*; but this mode could exist only in a rude state of society, and is now entirely abandoned. Coarse cloth still continues to form the staple article of Scotch manufacture, though factories for the making of fine cloth have been established in various parts of the country. Flannels, blankets, shawls, plaids, stockings and stocking-yarn, tartans, druggets, &c., are produced to a considerable extent at Galashiels, Hawick, Paisley, Bannockburn, Stirling, Kilmarnock, Jedburgh, and Aberdeen, as is more particularly noticed in the special articles on these places. In 1850 there were 188 woollen and worsted factories, with 233,533 spindles and 247 power-looms, employing 10,210 persons; and, in 1856, 202 woollen and worsted factories, with 293,363 spindles and 800 power-looms, driven by 3267 horse-power, of which 1487 was steam, and employing 10,175 hands, of whom 5179 were males and 4996 females. The power-loom has not hitherto been much employed in this manufacture; but it is being rapidly introduced, the number having more than tripled between 1850 and 1856.

The silk manufacture is still less considerable than that of woollen. Its seats are Paisley and Glasgow. In 1856 there were 6 silk factories, with 30,244 spindles, driven by 122 steam horse-power, and employing 837 persons, of whom 160 were males and 677 females.

Spirits. The favourite beverage of the people of Scotland has for a lengthened period been whiskey. Previously to 1823, owing to the high rate of duty, smuggling prevailed to a great extent in almost every district of the country, but especially in the Highlands. But in that year the duty was reduced from 6s. 2d. to 2s. 4½d. per imperial gallon, when the quantity of legally distilled spirits rose from 3,337,850 gals. in 1822 to 5,908,373 gals. in 1824, and 8,224,807 in 1825. The quantity charged duty for home consumption in Scotland in 1822 was 2,225,124 gals.; and in 1825, 5,981,549. In 1826 the duty was increased to 2s. 10d.; in 1831 to 3s. 4d.; and in 1840 to 3s. 8d. In 1855 it was farther increased to 4s. 8d.; in 1854 to 6s.; and in 1855 to 8s. per gallon. In 1850 there were 167 licensed distilleries in Scotland, and the quantity of proof spirits distilled during the year ending 5th January 1850 was 10,846,634 gallons, of which 6,058,086 were from malt only, and 4,788,548 from a mixture of malt with unmalted grain, sugar, or molasses. The number of gallons of proof spirits distilled in Scotland during 1857 was 13,299,409. Since the passing of the Act 18 and 19 Vict. cap. 94, allowing malt to be made, and sugar and molasses to be used for distillery purposes free of duty, in lieu of allowances and drawbacks, no separate account of the quantities of spirits made from these materials has been kept.

Since the repeal of the duty in 1830 we have no means of determining the quantities of ale and beer brewed. In 1829, 111,071 barrels of strong beer, and 229,384 barrels of table-beer were made in Scotland, yielding a duty of L. 71,787. The duty on strong beer was 9s. 10d., and on table-beer was 1s. 11½d. per barrel. The brewers are now subject to license duties, varying according to the quantity which they produce. In 1857 there were 223 brewers of

Statistics. strong beer, 11 brewers of table-beer, 23 retail brewers, and 15 brewers from sugar, licensed in Scotland. The number of bushels of malt consumed was 1,228,524. The principal seat of this manufacture is Edinburgh, but it is also carried on in many other places.

Malt. Malt has been largely made in Scotland from an early period. A duty was first imposed upon it in 1713; and in 1770 the quantity charged with duty was 1,762,460 bushels. In 1856 the number of bushels made by maltsters was 4,192,039; and in 1857, 5,131,876. In the latter of these years the numbers of bushels consumed by brewers was 1,228,524; and by distillers, 3,814,663.

Paper. Paper is a large and rapidly extending manufacture in Scotland. In 1837 the quantity produced was 13,781,383 lb.; in 1841, 16,821,354 lb.; in 1851, 31,723,001 lb.; and in 1857, 41,673,595 lb. The number of paper-mills in operation in 1838 was 49; in 1850, 48; and in 1856, 51. Paper was one of the first articles that was subjected to excise duties,—viz., as early as 1712. In 1737 the amount of duty collected was L.187; in 1790, L.5048; in 1820, L.52,182; in 1840, L.108,675; in 1850, L.187,687; and in 1857, L.271,662.

Among the more important of the other manufactures are, leather, soap, earthenware, glass, hardware, hats, and combs. The making of steam-engines, and every other description of machinery, as also the building of steam-boats, both of wood and iron, is carried on to a great extent, especially on the Clyde; and ship-building is largely carried on at all the chief ports.

Commerce. Previous to the Union, Scotland having little industry, and being thinly peopled, possessed only a very limited trade. Its exports were chiefly wool, skins, hides, and other raw materials; and its imports, corn, wine, spices, &c. Soon after the Union, however, the trade with the American and West India colonies began to awaken the commercial energies of the nation. In 1755 the exports amounted in value to L.535,576, and the imports to L.465,411. Since that time the rapid extension of its manufactures, aided by the discoveries and inventions of Watt, Arkwright, and others, has led to a corresponding increase of its commerce. In 1801 the exports amounted to L.2,844,502, and the imports to L.2,579,914. In 1851 the official value of the exports was L.17,871,869; and of the imports, L.8,921,108. The declared real value of the produce of the United Kingdom exported from Scotland in 1851 was L.5,016,116; and in 1857 it was L.8,136,708; of which, cotton yarn and manufactures, L.2,448,852; iron, wrought and unwrought, L.1,545,311; linen yarn and manufactures, L.832,692; herrings, L.445,016; woollen and worsted yarn and manufactures (pure and mixed), L.424,430; coals, cinders, and culm, L.288,199; haberdashery and millinery, L.247,131; machinery of all sorts, L.222,531; spirits, L.176,014; ale and beer, L.145,193. The principal ports from which these articles were exported were—Glasgow (L.5,103,318, chiefly cotton, linen, and iron manufactures); Leith (L.830,532, chiefly linen and iron manufactures); Greenock (L.502,899, chiefly iron and cotton manufactures); Grangemouth (L.445,078, chiefly iron manufactures); Irvine (L.246,588, chiefly iron and coal); and Dundee (L.230,020, chiefly linen yarn and manufactures).

Shipping. At the time of the Union in 1707, Scotland possessed only 215 vessels, having an aggregate burden of 14,485 tons. In 1800, its shipping amounted to 171,728 tons; in 1840, to 429,204 tons; in 1850, to 522,222 tons; and in 1857, to 639,557 tons. Of these last, the number registered as belonging to Scotland on 31st December 1857, there were 3214 sailing vessels, with 558,623 tons, of which 1170 vessels, with 35,405 tons, were of and under 50 tons burden each; and 294 steam vessels, with 80,934 tons, of which 66 vessels, with 1406 tons, were of and under 50 tons burden each. At 31st December 1858, 3543

vessels, having 652,675 tons, were registered at the various ports of Scotland, and that year 141 vessels, having 33,432 tons, were built. The following table gives the number of vessels and tonnage registered at the principal ports of Scotland on 31st December 1857:—

Ports.	Sailing Vessels.		Steam Vessels.		Total. Tonnage.
	Num-ber.	Tonnage	Num-ber.	Tonnage	
Glasgow....	458	162,355	153	56,591	218,046
Greenock....	386	83,304	30	5,739	89,043
Aberdeen..	252	65,814	15	4,347	70,161

Total..	3214	558,623	294	80,934	639,557

The number of sailing vessels entered coastwise in Scotland in 1857 was 15,129 (15,096 British and 33 foreign); their tonnage, 948,946 (944,660 British and 3286 foreign); the number cleared coastwise, 15,827 (15,800 British and 27 foreign); their tonnage, 915,556 (913,531 British, 2025 foreign). The number of steam vessels (all British) entered coastwise was 5961; tonnage, 1,254,360; the number cleared coastwise, 6020; tonnage, 1,246,404. The number and tonnage of the sailing and steam vessels entered and cleared at the chief ports in 1857 were:—

Ports.	Entered.		Cleared.	
	Vessels.	Tonnage.	Vessels.	Tonnage.
Glasgow.....	2,769	495,420	4,142	545,545

Total.....	74,736	2,203,306	21,847	2,161,965

The number of sailing vessels entered from the colonies in 1857 was 585 (560 British and 25 foreign); their tonnage, 248,368 (236,563 British, and 11,805 foreign); the number cleared for the colonies was 570 (547 British and 23 foreign); their tonnage, 257,621 (245,069 British and 12,552 foreign). The number of steam vessels (all British) that entered from the colonies was 10; their tonnage, 2426; the number that cleared for the colonies was 37; their tonnage, 13,325. The number and tonnage of sailing and steam vessels entered and cleared in the colonial trade at the chief ports were:—

Ports.	Entered.		Cleared.	
	Vessels.	Tonnage.	Vessels.	Tonnage.
Greenock.....	228	111,324	126	66,422
Glasgow.....	145	45,082	271	116,013
Port-Glasgow....	53	40,695	24	20,712

Aberdeen.....	17	5,469	12	4,663
Total.....	595	250,794	607	270,946

The number of sailing vessels entered from foreign ports in 1857 was 3936 (1357 British and 2579 foreign); their tonnage, 550,320 (233,781 British and 316,539 foreign); the number cleared for foreign ports was 4951 (2093 British and 2858 foreign); their tonnage, 678,687 (322,612 British and 356,075 foreign). The number of steam vessels entered from foreign ports was 391 (346 British and 45 foreign); their tonnage, 128,058 (117,479

Statistics. British and 10,579 foreign): the number cleared for foreign ports, 434 (354 British and 80 foreign); their tonnage, 136,715 (114,908 British and 21,807 foreign). The number and tonnage of sailing and steam vessels entered and cleared in the foreign trade at the chief ports in 1857 were:—

Ports.	Entered.		Cleared.	
	Vessels	Tonnage.	Vessels	Tonnage
Leith	1355	192,927	451	85,936

The following table shows the progress of shipping in the colonial and foreign and coasting trade for the seven years, from 1851–1857:—

	Coasting Trade		Colonial and Foreign		Total.	
	Inwards	Outwards	Inwards	Outwards	Inwards	Outwards
1851 .	2,010,988	2,105,224	663,321	753,312	2,674,309	2,858,536
1852... .	1,971,204	2,058,185	579,158	691,828	2,550,362	2,750,013
1853 .	1,904,270	2,003,581	720,047	902,005	2,624,317	2,905,586
1854... .	1,935,689	2,104,967	702,940	806,773	2,638,629	2,911,740
1855 .	1,963,552	2,057,936	668,078	840,150	2,631,630	2,898,086
1856 .	2,049,390	2,056,090	793,193	965,447	2,842,583	3,021,537
1857... .	2,203,306	2,161,965	929,172	1,086,348	3,132,478	3,248,313

Roads.

Until after the middle of last century there was scarcely a good road in Scotland. Even in the southern counties, corn, coal, turf, and even straw and hay, were usually carried upon the backs of horses. "Cadgers" plied regularly between different places, conveying goods in sacks or baskets, suspended one on each side of the horse. Where the distance, however, was considerable, it was necessary to use a cart, as all that a horse could carry on his back would not defray the expense of a long journey; and such was the wretched state of the roads that the time taken by the carriers (*i.e.*, those that used carts) is almost incredible. The common carrier from Selkirk to Edinburgh, 38 miles distant, required a fortnight for his journey going and returning. In 1678 an agreement was made to run a coach, with six horses, between Edinburgh and Glasgow, a distance of 44 miles, the double journey to be accomplished in six days; and even so late as the middle of last century, the stage-coach between these two towns took a day and a half to the journey. Soon after the rebellion of 1745, government began to open up the country by roads made by the military, hence called military roads, of which there were in all about 800 miles. These, however, were mostly confined to the Highlands, and were of little use for commercial purposes, being formed with little or no regard to such ascents and descents as do not impede the passage of an army.

Turnpike roads.

The turnpike roads and bridges in the Lowlands have, for upwards of a century, been made and kept in repair by means of tolls exacted from those who use them, under the authority of private acts of Parliament. The first of these acts was obtained in 1750. The roads are under the management of a board of trustees, who appoint clerks, collectors, surveyors, &c.; borrow money; enforce subscriptions; erect or remove toll-bars; reduce tolls or raise them as far as permitted by the local act; let tolls by public roup; provide tables of tolls, &c. By this means, and in consequence of the excellent materials that abound in all parts of the country, Scotland is now well supplied with turnpike roads, which are superior even to those in England. There are about 7000 miles of turnpike roads in Scotland, and 245

trusts. In the year 1854–55, the revenue received from tolls was L.216,661, and the total income from all sources, L.250,800; the total expenditure was L.248,347; and the total debt L.2,358,767. The expenditure for manual labour was L.84,956; for carriage of materials, L.9367; for materials for surface repairs, L.25,875; for land purchased, L.360; for damage done in obtaining materials, L.1004; for tradesmen's bills, L.5723; for salaries of treasurers, L.2138; of clerks, L.4768; of surveyors, L.11,672; for law charges, L.3587; for interest of debt, L.37,587; for annuities, L.500; for improvements, L.32,760; for watering roads, L.424; for debts paid off, L.18,923; for incidental expenses, L.9145.

In the Highlands, the nature of the country and the state of the population did not admit of the same system being carried out as in the Lowlands. The military roads, after being made, had likewise to be kept in repair at the public expense, for which L.5000 a year was usually granted by parliament. A great many new roads and bridges were also required; and in 1803 an act was passed by which parliament agreed to provide half the estimated expense of the necessary roads and bridges, the other half to be defrayed by the landed proprietors. There are now 938 miles of these, in the following counties:—Inverness, 383½; Ross, 210½; Sutherland, 96½; Caithness, 54; Aberdeen, 15½; Nairn, 20½; Moray, 8½; Banff, 2; Bute, 17; Argyle, 130½. The military roads have in many instances been allowed to fall into disrepair, but 255 miles of them are still kept up by the Commissioners for Highland Roads and Bridges. The total sum expended in keeping in repair these roads in 1857 was L.10,765, of which L.2372 was paid from the funds of the commissioners, and L.2745 from toll-dues, leaving L.5647 as the proportion payable by counties. There was a further sum of L.1015 expended in maintaining in repair 137 miles of roads in Caithness-shire, surrendered to the charge of the commissioners in 1838.

The Caledonian Canal, the greatest work of its kind in Britain, stretches S.W. and N.E. across the island, through the centre of the Highlands, from the Moray Firth, on the E. coast, to Loch Linnhe, on the W. It is 60 miles in length, but the greater part of it consists of three lakes or lochs,—Ness, Oich, and Lochy. The artificial portion, 23 miles in length, is 122 feet wide at the top, 50 feet at the bottom, and affords a maximum depth of 20 feet. Had it been executed as originally intended, frigates of 32 guns, and merchantmen of 1000 tons burden, might have been able to pass through; but owing to a wish to lessen the expense and to hasten the opening of the canal, parts of it were executed in a hurried and insufficient manner, and parts were not excavated to the proper depth, so that in some cases it is not more than 17 feet deep. It was executed entirely at the expense of the government, from the designs and under the superintendence of Thomas Telford, Esq. The total cost of the canal up to 1822, when it was opened, was L.905,258; and the aggregate outlay to the 1st of May 1839, was L.1,023,628. Nor has the income ever met the expenditure. In the year ending 1st May 1839, the expenditure was L.4170, while the income was only L.2532; and in the year ending 1st May 1859, the expenditure was L.6951, and the income only L.5080. It is not to be wondered at, therefore, that the question has more than once been debated, whether it would not be better to abandon the canal altogether. And now it is less necessary than formerly to maintain it, seeing that all the principal ports of the east and west coast are connected by railway. During the year ending 1st May 1859, the passages through the canal from E. to W. were 387; from W. to E. 289; on parts of the canal, 289; passages of steamers, 467; and the total dues collected on these L.3916.

The Crinan Canal is situated in Argyleshire, and stretches across the Mull of Cantyre, from Loch Gilp to Jura Sound.

Statistics. It was originally undertaken in 1793 by a company of shareholders, but the sum subscribed (£108,000) being insufficient for the completion of the work, the government advanced the money, and the canal was transferred, on mortgage, to the Barons of Exchequer in Scotland. The management since 1817 has been in the hands of the Commissioners of the Caledonian Canal. It is 9 miles long and 12 feet deep, admitting vessels of 200 tons burden. In the beginning of February last (1859), one of the great reservoirs by which the canal is supplied with water burst, and did great damage to the canal and adjacent country. It is, however, in course of being repaired. Notwithstanding the disaster by which the traffic of the canal had been almost wholly suspended for three months, the receipts of the year ending 1st May 1859 amounted to £2238, and the payments to £2150, leaving a balance of £88. In the previous year there was a deficiency of £90, which led to a rise in the rates on certain classes of goods.

Forth and Clyde, &c. The Great Canal, uniting the Firths of Forth and Clyde, was begun in 1768, but not finally completed till 1790. Its length from Grangemouth, on the Forth, to Bowling Bay, on the Clyde, is 35 miles, or including the lateral branch to Port-Dundas, Glasgow, 38½ miles. Its average width at the surface is 56 feet; at the bottom, 27 feet; general depth, 10 feet. It is understood to have been very profitable to the proprietors. The Union Canal, which was finished in 1822, stretches from Port-Hopetoun, Edinburgh, until it joins the Forth and Clyde Canal at Port-Downie, near Falkirk, a distance of 31½ miles. Its depth is only 5 feet, so that its traffic is very limited; and all altogether it has been a very unprofitable undertaking. The Monkland Canal stretches from Glasgow to Woodhall, about 2 miles S.E. of Airdrie, a distance of 12 miles, and communicates by a lateral branch with the Forth and Clyde Canal at Port-Dundas. The Glasgow, Paisley, and Ardrossan Canal has never been completed. It extends from Port-Eglinton, near Glasgow, to the village of Johnstone, a distance of 11 miles, and was opened in 1811. It was on this canal that the experiment was first made in rapid travelling, showing that it was practicable for a properly constructed boat to proceed at the rate of nine or ten miles an hour without injury to the banks.

Railways. The first railway formed in Scotland was that between Kilmarnock and Troon, a distance of 9½ miles. The act for the formation of this railway, or rather tram-road, was passed in 1808, and it was opened in 1810. It was followed by the Monkland and Kirkintilloch Railway, 11 miles in length, connecting the rich coal and ironstone district of New and Old Monkland with the Forth and Clyde Canal, near Kirkintilloch. In 1849, there were 795 miles of railway in operation; in 1853, 987; and in the end of 1857, 1243; of which 409 miles were single lines. Besides these, at last mentioned date, there were 573 miles authorised but not opened. The total number of passengers conveyed in 1857 was 14,733,503, of whom 1,823,542 were first class; 2,180,284, second; 10,723,694, third and parliamentary; and 5983 mixed, or not duly apportioned into classes. The receipts from passengers were £916,697; from goods, £1,584,781; total, £2,501,478. The total amount authorised to be raised by railways in Scotland to 31st December 1857 was £38,222,976, of which £33,668,115 was actually raised—£16,756,881 by ordinary shares, £7,700,808 by preference and guaranteed shares, and £9,210,426 by loans. The total amount of working and preferential charges in 1857 was £1,846,999. Of the preferential charges £354,774 were charges for interest on preference and guaranteed shares; and £401,775 charges for interest on loans. The average cost per mile of railways in Scotland has been £28,225; but for independent lines authorised and opened since 1848 it has been only £7243. See article RAILWAYS.

The following table will show the progress of railways since 1849. It gives the mean length of railway open in each year from 1849 to 1857; the capital raised per mile open; the average number of passengers; and the average receipts from passengers and goods per mile; together with the proportion per cent. of traffic to capital raised.

Statistics

Year.	Mean Length.	Capital raised per Mile.	No of Passengers per Mile.	Receipts per Mile per Annum from		Proportion of Traffic to Capital raised.
				Pass'gers	Goods.

1857.....	1226	28,225	12,017	746	1293	7.22

A duty of one halfpenny per mile for every four passengers conveyed by railway was imposed in 1832. In 1842 this was altered to the present duty of 5 per cent. upon the receipts from passengers. In 1844 an act was passed requiring railway companies to run cheap trains, at least once daily from each end of their lines, for the benefit of the poorer classes, at a rate not exceeding one penny for each mile travelled, and granting an exemption from duty on the receipts from such passengers. The powers of central control over railways, which, in 1846, were vested in a board of railway commissioners, were, in 1851, restored to the Board of Trade.

The great advance made by Scotland since the time of the Union, is indicated by the increase that has taken place in her public revenue. In 1707 it amounted to no more than £110,694; in 1788 to £1,099,148; in 1813 (including the property-tax and other war taxes) to £4,204,097; in 1822 (the property-tax, &c., having been repealed) to £3,436,642; in 1839 to £5,254,624; in 1846 to £5,586,756; in 1851 to £6,154,804; and in year ending 31st March 1858, to about £7,300,000. The principal sources of revenue are the *Customs, Excise, Stamps, Land and Assessed Taxes, Property and Income Tax, and Post-Office*.

The gross amount of customs collected in Scotland for the year 1836 was £1,129,802; in 1844 it was £1,864,148; in 1850, £1,951,981; in 1856, £2,188,379; and in 1857, £2,024,093. The chief ports, with the amount of duty collected at each in 1857, were—Glasgow, £752,263; Leith, £486,646; Greenock, £448,318; Aberdeen, £92,036; Dundee, £58,703; Port-Glasgow, £56,174. The number of officers was 532, and the amount of their salaries, £56,448.

The gross amount of excise duties collected in Scotland in 1849 was £2,838,397; in 1851, £2,899,338; and in 1853, £3,045,471. In 1850 the duty on bricks was abolished, and in 1853 the duties on soap and post-horses. The following table gives the amount of duties collected on the several articles for each year, from 31st March 1854 to 31st March 1859:—

Description.	1854.	1855.	1856.	1857.	1858.

Land-tax. The land-tax, which previously existed in England, was introduced into Scotland at the time of the Union, and was fixed at the rate of 4s. upon the pound of the then valued rental. The amount it yielded was L.47,954. The rate has varied at different times from 4s. to 1s. per pound, but the valuation has remained fixed. In 1798 this tax was made perpetual at its original rate, but subject to redemption, a privilege which, however, has been but sparingly taken advantage of. In 1858 this tax yielded a gross sum of L.35,596.

Assessed taxes. The assessed taxes comprise duties on inhabited houses, servants, carriages, horses, dogs, game, &c. In 1849 they produced L.258,149; in 1851, L.256,748; and in 1853, L.163,014. The deficiency in the last of these years arose from the repeal of the window tax, yielding about L.124,000 annually, for which was substituted a duty on inhabited houses, which produced about L.42,000. In 1854 the rates of duty were considerably reduced, and were rendered more simple and uniform by the abolition of the progressive duties and of several exemptions. The following table gives the gross amount collected on each branch in each of the five years preceding 31st March 1859:—

Description.	1854.	1855	1856.	1857.	1858.
	L.	L.	L.	L.	L.

Total	185,351	159,823	150,990	174,849	163,674

Income-tax. The income-tax was first had recourse to by Mr Pitt in 1798, to supply means for carrying on the war. It first took the form of an increase of assessed duties to each person who possessed an income of L.60 per annum and upwards; but next year it was changed to a duty of 10 per cent. on incomes of L.200 and upwards, with modified rates on incomes between L.60 and L.200. This tax was repealed in 1802, after the peace of Amiens; but was revived again the following year, a rate varying from 3d. to 11d. per pound being imposed upon all incomes between L.60 and L.150 per annum, and 5 per cent. on all incomes

amounting to or exceeding this latter sum. In 1805, an additional duty of one-fourth of the above rates was imposed; and in 1806, the duty was raised to 10 per cent. on incomes of L.150 and upwards, and only professional incomes under L.50 were exempted from taxation. This tax ceased in 1816, and was not revived till 1842, when it was reimposed by Sir Robert Peel's government for the purpose of meeting the deficiency which then occurred in the revenue, and to enable the government to make some reforms, with the view of improving the commerce and manufactures of the country. The rate imposed was 7d. in the pound on all incomes of L.150 and upwards, exemption being granted to all persons whose income was under that sum. It was first imposed for three years, but in 1845 it was continued for three years longer at the same rate, and again for another three years. In 1851 it was continued for one year, and in 1852 for another year.

In 1853, Mr Gladstone introduced an act by which the tax was reimposed for a period of seven years, after which it was to cease entirely. By this act the original rate of duty of 7d. in the pound was continued for two years; 6d. in the pound was imposed for the next two years; and 5d. in the pound for the remaining three years, ending 5th April 1860. The rate of duty on incomes between L.100 and L.150 was fixed at 5d. in the pound annually during the whole seven years. On the declaration of the war with Russia, it was found necessary to double the income-tax from the 5th April 1854; and a farther increase was afterwards imposed, from the 5th April 1855, of 2d. in the pound, on incomes of L.150 and upwards, and of 1½d. in the pound on incomes between L.100 and L.150. In 1857, the rates were reduced to 7d. and 5d. in the pound respectively; and in 1858, the former of these was farther reduced to 5d. In 1859, the rates were again raised to 9d. in the pound on incomes of L.150 and upwards, and to 6½d. in the pound on incomes between L.100 and L.150. The following table gives the nett amount of property and income-tax collected in Scotland in each of the eleven years, from year ending 5th April 1847 to 5th April 1857, under each schedule. Schedule A applies to incomes arising from lands, houses, mines, and other heritages in respect of *property*; schedule B to incomes arising from the above in respect of *occupancy*; schedule D to incomes derived from trades, manufactures, professions, or employments; and schedule E to salaries and emoluments of office of all persons employed in public offices:—

Year.	A.	B.	D.	E.	Total.
	L.	L.	L.	L.	L.
1847.....	266,439	23,137	163,688	12,458	465,722
1848 ...	274,401	23,308	154,342	13,097	465,148
1849.....	284,239	23,796	135,861	13,973	457,869
1850	285,396	23,162	132,275	13,755	454,588
1851.....	282,216	22,778	138,288	14,381	457,663
1852	289,206	22,453	140,720	15,159	467,538
1853	290,484	22,592	145,332	15,397	473,805
1854	321,171	28,408	186,523	18,312	554,414
1855.....	656,805	58,396	386,133	39,396	1,140,730
1856	767,679	69,026	432,811	49,211	1,318,727
1857.....	774,302	70,711	442,417	52,405	1,339,835

The amount of property and income charged duty for year ending 5th April 1857 was, under schedule A, L.11,657,882; B, L.2,806,855; D, L.6,856,106; E, L.818,376,—total, L.22,139,219; for 1858, A, L.12,529,689; B, L.3,397,365; D, L.7,107,287; E, L.869,627,—total, L.22,563,238. The annual value of real property assessed under schedule A, in 1843, was L.9,481,000, showing an increase of nearly a fourth in fifteen years.

The number of persons charged under schedule D, on incomes derived from trades and professions in 1857, was 26,190, of whom more than one-half, or 13,567, were from L.100 to L.150; 3331 under L.100; 2749 from L.150 to

Statistics. L.200; 2393 from L.200 to L.300; 1281 from L.300 to L.400; 640 from L.400 to L.500; 1282 from L.500 to 1000; and 947 L.1000 and upwards.

Post-office. On 10th January 1840 the penny postage system was introduced, and since that time the number of letters delivered in the United Kingdom has increased more than sixfold. The gross revenue for year ending 5th January 1839 (the last complete year before the reduction) was L.2,346,278; and for the year ending 31st December 1857, it was L.3,035,713: the nett revenue in the former case was L.1,659,509; and in the latter, L.1,314,898—the difference arising from the increased cost of management, which in 1839 was only L.686,768, and in 1857, L.1,720,815. The gross revenue from postages in Scotland, in 1857, was L.271,906, being an increase of L.17,473 on that of 1856; and the commission on money-orders was L.8463, being an increase of L.466 on that of 1856. The number of chargeable letters delivered in the United Kingdom in 1857 was, as nearly as can be estimated, 504,421,000, being an increase on the previous year of $5\frac{1}{2}$ per cent.; in Scotland, 51,612,000, showing an increase of 7 per cent. The colonial and foreign letters were less than one-fiftieth of the number delivered; and about one letter in every 400 was registered. The proportion of letters to each individual in the United Kingdom was about 17; in Scotland, about 16. The number of free newspapers delivered in the United Kingdom, in 1857, was about 51,616,000; in Scotland, 7,245,000; the number of book-packets and chargeable newspapers (*i.e.*, not bearing the newspaper stamp) delivered in the United Kingdom in 1857 was 25,193,000; in Scotland, 3,623,000. The number of money-orders issued in the United Kingdom, in 1857, was 6,389,702; and their aggregate amount was L.12,180,272, affording a clear profit of L.24,175. In Scotland the number was 512,874; amount, L.950,872; clear profit, L.1180. Of the number of orders issued in Scotland, 350,178 were of and under L.2, and 162,697 above L.2 and not above L.5.

Poor-laws. Though poor rates were not generally imposed in Scotland till very recently, yet as early as 1579 an act was passed by the Scottish Parliament involving a compulsory assessment for the support of the impotent poor. Down to the middle of the last century, however, the weekly collections, under the management of the kirk-session, were in general found sufficient for the support of the poor, except in years of peculiar pressure or scarcity, when in some cases temporary assessments were resorted to. Assessments have only been introduced as a last resort, and only when the poor could not otherwise be supported. Hence we find that, in 1838, only 236 parishes were legally assessed in Scotland, and 126 voluntarily assessed, while 517 were unassessed. These assessments were most common and heaviest in the parishes bordering on England; and except in the case of the larger towns, they decreased or disappeared as they receded from the contaminating influence of the sister kingdom. Thus, every parish in the Synod of Merse and Teviotdale was burdened with assessment, while in the midland synods less than the half of the parishes were assessed; and in the northern synods, embracing 157 parishes, only three were subjected to that burden.

In 1845 an act (8 and 9 Vict. c. 83) was passed for the amendment and better administration of the laws relating to the relief of the poor in Scotland. It established a board of supervision to inquire into the management of the poor throughout Scotland, and to make an annual report of its proceedings. This statute placed three modes of assessment in the option of parochial boards, subject to the sanction of the board of supervision:—(1.) One-half of the assessment may be imposed upon the owners, and the other half upon the tenants, or occupants of all lands and heritages within the parish rateably, according to the annual

value of such lands and heritages. (2.) One-half of the assessment may be imposed upon the owners of all lands and heritages within the parish, according to the annual value of such lands and heritages; and the other half upon the whole inhabitants, according to their means and substance, other than lands and heritages situated in Great Britain and Ireland. (3.) The whole assessment may be imposed as an equal percentage upon the annual value of all lands and heritages within the parish, and upon the estimated annual income of the whole inhabitants from means and substance, other than lands and heritages situated in Great Britain and Ireland. The act farther permitted the continuance of any other mode of assessment established in any parish by a local act or by usage. The following table gives the number of parishes assessed in each mode for each year (ending August) since the institution of the board:—

Mode.	1846.	1847.	1848.	1849.	1850.	1851.	1852.	1853.	1854.	1855.	1856.	1857.
First	323	431	471	499	524	534	554	567	581	593	630	657
Second	35	37	40	34	30	30	30	29	24	24	17	3
Third	31	34	36	40	40	39	37	35	35	34	34	28

Total assessed	445	558	602	625	644	653	671	680	689	700	716	729
„ unassessed	435	322	278	255	236	228	211	202	194	183	167	154

The sums received from all sources for the relief of the poor were, in 1836, L.171,042; in 1845–6, L.306,044; in 1856–7, L.669,852. Of this last sum there was expended for relief of poor on the roll, L.485,803; relief of casual poor, L.20,719; medical relief, L.23,730; management, L.61,553; law expenses, L.7399; poor-house buildings, L.27,277; general sanitary measures, L.1122. The number of registered poor, on the 14th of May 1857, was 69,217 (a decrease of 10,756 since the same date in preceding year); the number who had died, or ceased to receive relief during the year, was 19,405; and the number of casual or unregistered poor was 36,545.

The supreme court in civil matters is the Court of Ses- Courts of sion, consisting of thirteen judges. They act in what is justice, &c. called the “Inner” and the “Outer” house. The Outer-House is the court of first instance, whence litigations pass to the Inner as to a court of review. Five of the junior judges sit in the Outer-House, each holding a separate court, which, to distinguish it from the Inner-House, is called the court of a Lord Ordinary. The Inner-House is partitioned into two divisions, each consisting of four judges. An ordinary litigation in the Court of Session comes first before a Lord Ordinary, and may be taken for review to one of the divisions of the Inner-House, where a decision is a decision of the Court of Session. It is practicable, however, when occasion demands, to have the judgment of the whole court on a point. The decisions in the Court of Session are under certain restrictions, liable to be brought by appeal before the House of Lords. See APPEAL. Causes may be taken into the Court of Session from local courts by a process called “advocation.”

The supreme tribunal for matters criminal is the Court of Justiciary, consisting of five of the judges of the Court of Session. The High Court of Justiciary, as it is termed, sits in Edinburgh, but Circuit Courts of Justiciary are held, four in Glasgow, and two in the other circuit districts, annually. This court has jurisdiction in all criminal charges, except those which are reserved by statute for summary trial in inferior tribunals. There are points which can be referred from the circuit courts to the High Court of Justiciary, but from this tribunal there is no appeal, nor can it review its own judgments. The head of this Court is the Lord Justice-General, whose title represents that of the ancient Justiciar of Scotland. The offices of Lord Justice-

Statistics. General and President of the Court of Session are now united.

The most important local courts are those of the sheriffs. There is at least one sheriff-court in each county. The immediate business of the court is conducted before the sheriff-substitute, who resides within the county, where he is the Sovereign's immediate representative, enforcing the decisions of the courts of law generally, and superintending everything done under the authority of what is called "the executive." The sheriff-substitute, as his title implies, acts for a principal, who has, within certain limits, a power to revise his proceedings, while there are certain acts, both judicial and executive, which must be performed by the sheriff-principal. By an act passed in 1855, arrangements were made for grouping the counties into districts; and one sheriff-principal serves for all the counties of each district. There was previously a sheriff-principal as well as a sheriff-substitute for each county, and the new arrangement was adopted under the view, that although there might be work enough for a sheriff-substitute in a county, or for several, as in the county of Lanark, the office of principal-sheriff of any of the smaller counties was apt to degenerate to something little above a sinecure.

There is no limit to the importance, in a pecuniary scale, of the questions of civil right that may be tried in the court of the sheriff. Its operation is of course restrained by the local limits of the sheriff's jurisdiction. He has no authority in questions of feudal rights, or, in other words, of land rights. Nor can he decide questions of status, as it is termed, such as marriage or legitimacy. The peculiar Scottish action called a "Declarator," by which a person who is neither prosecuting another nor defending himself, but establishing a right liable to be called in question, is excluded from the sheriff-court. The proceedings in the civil department of the ordinary sheriff's court are chiefly conducted in written pleadings. For the recovery of small debts, the sheriff has a separate court, in which the procedure is oral and summary. In the criminal department of the sheriff's court, those cases are tried which the crown lawyers do not think it necessary to bring before the Court of Justiciary. As the sheriff has not authority beyond his district, transportable offences could not be adjudicated by him, and the exclusion now of course applies to the punishment of penal servitude. The punishment of death is within the power of the sheriff by the theory of the law, but has been long abandoned in practice. Justices of peace appointed under royal commission, as in England, and magistrates of municipal corporations, have jurisdiction in Scotland, both in civil and criminal matters. Their authority, however, limited by law and custom, is practically left to a still narrower sphere, by the efficiency of the jurisdiction exercised by the sheriffs, who are professionally trained and responsible judges.

The law administered by the Scottish tribunals differs fundamentally from the law of England. This difference will be found to have originated in the antagonism between

Statistics. the two countries, created by that war of independence which ended in the establishment of Bruce's kingdom in Scotland. The records of the laws and customs of the two countries anterior to that war show that there was then little fundamental difference between them. Scotland, however, having to support her national independence against so powerful a neighbour, fell into alliance with France. Hence her laws, and to some extent her institutions, followed the example of that country. The Court of Session, for instance, was an imitation of the Parliament of Paris. So far as Scotland took her laws from France, she received them from those two great fountains of the Roman and the feudal law which supplied all the continental nations with their jurisprudence. In England the common law owes more to the Justinian system than the old school of English common lawyers would have readily admitted; but Scotland received the whole of the civil law as authority, unless when the field was occupied by the feudal law. Hence the whole of the Justinian system, and the numerous comments on its various parts by French and German jurists, were the study of the Scottish lawyers, while those in England perused the year books and the works of the commentators who restricted their views to precedents purely English. Both England and Scotland drew from the feudal law, but both in a different fashion. The Scottish system of law rights became more purely and scientifically feudal than the English, carrying out a hierarchy of subinfeudation from the monarch, the supreme over-lord, through nearly any number of grades of sub-vassalship. If this system had its political and its economical inconveniences, it had the effect of establishing a thorough and scientific system of land registration in Scotland. In many points the laws of England and of Scotland have since the union been assimilated by statute. In the criminal department, the continental characteristics are still preserved in the institution of public prosecutors. A private person may prosecute in Scotland on a criminal charge, but partly from difficulties in carrying out such proceedings, and far more because they are rendered unnecessary by the ample official organization for the administration of the criminal law, the private prosecution of criminal charges is virtually unknown.

For fuller information on the law and judicature of Scotland, see ADVOCATE, AGENT, APPEAL, ARREST, ARRESTMENT, BANKRUPTCY, CHARTER, CONVEYANCING, CORPORATION, ENTAIL, HUSBAND AND WIFE, INFERTMENT, INHIBITION, JOINT-STOCK, JURY, LEASE, PARENT AND CHILD, &c.

For information on subjects connected with Scotland, not noticed, or only glanced at in this article, see such headings as MONEY, SAVINGS BANKS, PARLIAMENT, MUNICIPAL CORPORATIONS, POLICE, PRISONS, &c.

It only remains to add, that of this article the physical description and geology are by Professor Nicol of Aberdeen; the climate and agriculture by Robert Russell, Esq., author of *North America, its Agriculture and Climate*; the botany by Professor Balfour of Edinburgh University; and the judicature by J. H. Burton, Esq., advocate.

Scott,
David.

SCOTT, DAVID, a Scottish painter of unquestionable genius, was the fifth child of Robert Scott, a landscape-engraver, and was born in Edinburgh on the 10th or 12th of October 1806. A year after his birth, he was the only surviving child of the family, the rest having been cut off within a few days by a prevalent epidemic. From this blow, it is said, neither father nor mother ever recovered; and David Scott grew up under the shade of religious melancholy and gloom. If this constant fostering of the memories of the dead, so characteristic of certain classes of the Scottish people, did not create in young Scott that sad, brooding, imaginative disposition, which was so noticeable a part of his character, it at least had the effect of being highly advantageous to its development. David Scott grew up silent, earnest, and imperious. He never "whistled or sang" like other youths, but plodded eagerly at his Latin, in which he made but very slow progress, or amused his leisure hours in drawing rude designs of his own from "Paradise Lost," "Macbeth," or Scottish and Greek history. The same impulse continued to the end of his life; the same aim actuated all his artistic career. When he came to his full stature, he was tall and of a delicate build, with very fine features, and an uncommonly large dark-blue eye. He began his artistic career by assisting his father in his business of a landscape-engraver, but it was his business to become a painter. He accordingly began a painting of "Lot and his Daughters fleeing from the Cities of the Plain," designed on an enormously large scale, which was returned from the British Institution as too large. Heedless of this hint, he held on his course and painted pictures which would have required a hall for their exhibition, and which the public would neither admire nor buy. The "Hopes of Early Genius dispelled by Death" was exhibited in 1828; and his "Fingal and the Spirit of Lodi," "Adam and Eve," "The Death of Sappho," "Wallace defending Scotland," were painted during the next year. He sold his first picture "The Cloud" in 1831; and during the same year appeared his outline sketches of the "Monograms of Man." He likewise began this year his series of splendid designs for Coleridge's "Ancient Mariner," which were published after his return from Rome in 1837. The poet, on being shown these designs, expressed his satisfaction with them; adding, at the same time, that he had not thought it possible to illustrate such a piece. Such was Scott's progress up to the year 1832. His devotion to high art was quite enthusiastic; and it was utterly in vain that men tried to convince him of the entire unremunerative department of art to which he devoted his nights and days, his dreams and reveries. As Dr Samuel Brown said of him, who knew him well and loved him ardently, "he was self-willed, yet sensitive; ambitious, but despising the arts of rising; impulsive and industrious; well-informed, but imaginative; studious, yet imperiously original." (*Essays*, two vols., 1858). In 1832, after painting "Nimrod," "Cain," "Sarpedon carried by Sleep and Death," "Pan," "Aurora," and the Sketch of "Burying the Dead," he set out for Italy, staying some time at the Louvre in Paris on his way southward. He passed through the towns of Geneva, Milan, Venice, Parma, Bologna, Florence, and Siena, on his journey to Rome, which city he reached on the 8th of December 1832. While on this Italian tour he painted immensely, and gained great facility in execution, without, however, essentially changing his style. The grand style had been born with him in Edinburgh, and so entirely original was his genius, that Rome and all Italy could not weed it out of him. He painted a very large picture of "Discord" while resident in Rome, which was much admired by the artists who came to visit this solitary Scotsman in his solitary studio. One of Scott's earliest undertakings on his return to Edinburgh in 1834, was to paint a "Descent from the Cross" for St Patrick's Chapel,

Lothian Street, which proclaimed him, on its exhibition the following year, to be no longer the student but now the master in art. From this period he continued to paint with remarkable diligence and with remarkable ambition, a series of paintings as wonderful for their astonishing excellencies, as they were for their want of power to interest the general spectator. The artist, it was evident, despite his long practice and his untiring study, had not yet attained to the full and adequate expression of which his nature was capable. That the elements of a great painter were now visible in every line he drew and in every hue he painted, no adequate judge could for a moment doubt, but whether he ever could so nicely harmonize all his remarkable artistic gifts, and set them forth in the full and fair proportions of nature, was a question which time alone could solve. He had now attained to near the age of thirty, but his nature was of slow growth, and the few who knew him well had great confidence in his future, provided his health would keep good. His strength had never been robust, and his isolated, determined devotion to art, and to everything worthy of the name of art, had by no means increased his bodily vigour. He sent to the Exhibition in Edinburgh, in 1835, four pictures—"Sappho and Anacreon," "The Vintager," "A Fresco," and a "Sketch of the Head of Mary Magdalene;" and in 1836, "The Abbot of Misrule," and "Judas betraying Christ." During the same year he had painted, for a prize, "Lady Macbeth leaving the Daggers by the Sleeping Grooms." His appearance in the Scottish Royal Academy was made in 1838 by "Orestes seized by the Furies," "Rachel weeping for her Children," "Puck fleeing before the Dawn," and "Ariel and Caliban," the last of which is characterized by the painter's brother, W. B. Scott, himself both an elegant poet and a fine painter, as "perhaps the most truly poetic production" of the artist. During the same year he painted his "Alchymist," a really noble picture. In the year 1839 he had etched several large plates of the "Last Judgment" of Michael Angelo, which he had made in Rome some years ago, and which were designed for publication. Publishers were slow, however, to undertake this project; and accordingly his Essay, which he intended to accompany these prints as letter-press, "On the peculiarities of Thought and Style," was accepted by *Blackwood's Magazine* in the month of February 1839. This was followed up by papers on the genius of Raphael, on Titian, and Venetian painting; on Leonardo da Vinci and Corregio, and on the Caracci, Caravaggio, and Monachism in March 1841. These remarkable pieces of critical literature abounded, says Dr S. Brown, with "knowledge, fancy, reasonableness, imagination, and poetic insight;" so that, in spite of their literary shortcomings, they will yet be read as long as men admire what is highest in art and what is truest in its historical embodiments. The proposition which lay at the basis of all these dissertations, and which never forsook the artist in life, was, that "the sole purpose of art is the sustaining of humanity in man." In 1840 he exhibited his painting of the "Agony of Discord, or the Household Gods destroyed," on which he had been long engaged; "Philoctetes," "Cupid sharpening his Arrows," and the "Crucifixion;" in 1841, he produced "Queen Elizabeth in the Globe Theatre," "Queen Mary," "The Death of Jane Shore," "Ave Maria," and "A Parthian Archer." This year was an uncommonly fertile one with Scott, for he not only made the sketches of forty designs for the *Pilgrim's Progress* (afterwards published by Fullarton and Co.), and painted the "Duke of Gloucester taken into the Water Gate of Calais," "Silenus praising Wine," and "The Challenge;" but he likewise began the great painting of his life, "Vasco de Gama encountering the Spirit of the Cape." From this year till his death he worked on with untiring devotedness, following always his own conception, without

Scott,
David.

Scott,
John.

in any case humouring the taste of the public. His stern will, amounting occasionally to wilfulness, toiled on in comparative poverty, apparently thoughtless of whether he painted what would please or not. His "Richard III.," "The Four Great Masters, Michael Angelo, Raphael, Titian, and Corregio," and the "Belated Peasant," were exhibited in 1843. He produced during the following years—"Wallace the Defender of Scotland," "Sir Roger Kirkpatrick stabbing the Red Cummin," "The Baron in Peace," and "May." The "Christian listening to the instructions of Piety, Charity, and Discretion," and the "Dead Rising at the Crucifixion," were two of his most remarkable productions. His pictures in 1846 were, "Peter the Hermit," "Dante and Beatrice," "The Fall of the Giants," "Rhea," and the "Ascension." Next year he exhibited on the walls of the academy in Edinburgh only one painting, "The Triumph of Love," a wonderful piece of colouring, considered his masterpiece in this respect. "Time surprising Love," "Children following Fortune," "Queen Mary of Scotland at the place of Execution," "Hope passing over the Sky of Adversity," and the "Baptism of Christ," were all finished in 1848. He was unsuccessful in his competition for the execution of frescoes for the new Houses of Parliament; but this did not much damp his courage. The lamp which had burned so long in comparative obscurity was now to send forth a full, fiery blaze of light before being extinguished for ever. He had just finished his great painting of "Vasco de Gama," on which he had been engaged for years, and the critics were speaking of it with quite unwonted enthusiasm; but it was too late, the painter was dying. He felt he had not yet succeeded in adequately giving expression to his nature; but in this painting, which is now in the Trinity House, Leith, he felt he had come nearer reconciling his own ideas with the public taste than he had ever done before. "If I could," he said a few days before his death, "but have time yet, I think I could meet the public in their own way more, and yet do what I think good. But it is over, and here I lie." He never rose again, but died on the 5th of March 1849.

David Scott was, without doubt, the greatest example on record, among Scottish artists, of a great painter nobly struggling up towards the light and freedom of clear articulate expression in art, whose fire was quenched ere his work was done. His whole life was a fight, and the struggle was not quite ended when his own end came. It was nearing its close, however, and a few years more of the kindly sunshine of success, might, by lessening his opinionativeness, have modified his views of nature, and given him a larger and more genial power of artistic expression. But such was not vouchsafed to him; and men must strive to read and to learn from this man's life, as they have likewise to do from many other mysterious problems, what of noble and great was in it, leaving what of meanness or littleness they may chance to find in it, to be trodden under foot of men. Some beautiful specimens of David Scott's poetry are given by his brother W. B. Scott, in his very able and kindly tribute to the memory of the artist. This *Memoir* was published in 1850.

SCOTT, John, Baron Eldon, Lord High Chancellor of England, was born 4th June 1751, in Love Lane, Newcastle. His ancestors were obscure, though respectable, and he had the merit of raising himself, by his talents, to the highest honours in the State.

His grandfather, William Scott, of Sandgate, a suburb of Newcastle, was a clerk to a "fitter"—a sort of water-carrier and broker of coals, engaged either as a merchant or on commission, in conveying coals from the pits in "keels," or barges, to the lower ports of the Tyne. His father, whose name also was William, began life as an apprentice to a "fitter" in which service he obtained the freedom of Newcastle, becoming a member of the guild of Hoastmen;

later in life he became a principal in the business, adding to his income by keeping a public-house near the quay of Newcastle, to supply drink to his keelmen, on the modern truck system; he also engaged somewhat in speculations in shipping and the maritime insurance called bottomry. In these various occupations he attained a most respectable position as a merchant in Newcastle; he led a quiet and prudent life outside what is called "society;" and accumulated property worth nearly £20,000. He was twice married; his second wife, the mother of John Scott, was a daughter of a Mr Atkinson, also a "fitter" in Newcastle—"a woman," says Lord Campbell (*Life of Lord Eldon*, p. 4), "who was a model of all the domestic virtues, and of such superior understanding, that to her is traced all the extraordinary talent which distinguished her two sons, William and John—Lord Stowell and Lord Eldon." Besides the two just named, there was a third and intermediate son, Henry, who followed his father's business of merchant and fitter in Newcastle. It may be mentioned, as a peculiar circumstance, that William and John were each of them one of twins, each having been born with a sister.

The boys were educated under the Rev. Hugh Moises, at the grammar school of their native town, where William and John, at least, exhibited excellent talents, and secured the affection of their master, without, however, giving promise of the splendid careers which they were destined to run. This Moises was a gentleman of good scholarship and varied accomplishments, and, if we are to credit Dr W. E. Surtees (*Sketch of the Lives of Lords Stowell and Eldon*, 1846), exercised a singular influence on the characters of his two pupils. He combined the opposite qualities of a smart, sparkling, after-dinner talker, and canting hypocrite—mixing in his conversation small jokes, and grave appeals to his conscience and God. William and John assumed each of them one of the elements of this composite character—the former becoming remarkable for the brilliancy of his conversation, and the latter for the frequency with which he would call God to witness the purity of his intentions. Be the origin of this canting habit in John what it may, it must be stated that when under Mr Moises' charge, he was not remarkable for his application to his studies, though his wonderful memory enabled him to make good progress in them; he frequently played truant, and got whipped for doing so; robbed orchards, and indulged in other questionable school-boy freaks, which might here be overlooked as symptoms merely of surplus energy and love of adventure, could it be added that he always came out of his scrapes with honour and a character for truthfulness. The boy is father to the man; and in Johnnie Scott telling fibs to evade the tawse, may be seen the rudiments of the Lord High Chancellor falsifying history to escape the merited censure of mankind.

William Scott, who was John's senior by nearly six years, was fortunate enough, on leaving school, to obtain a Durham scholarship at Corpus Christi College, Oxford, to which he was eligible through the accident of having been born in the county of Durham. He accordingly proceeded to the University, where he distinguished himself so greatly that, in December 1764, in his eighteenth year, he obtained a fellowship at University College, of which he afterwards became a tutor, an office in which he acquired a high reputation for himself and college. This success determined the career of his youngest brother. When John had finished his education under Mr Moises, his father thought of apprenticing him to his own business, to which Henry had already devoted himself; and it was only through the interference of William, whose affection for him was as strong as his opinion of him was high, that it was ultimately resolved that he should continue the prosecution of his studies. Accordingly, on the 15th May 1766, he entered University College as a commoner, with the view of entering the Church,

John.

and obtaining a college living. In the year following he obtained a fellowship, and in the summer of 1771 won the prize for the English essay, the only university prize open for general competition in his time. It does not appear, however, that he distinguished himself at college any more than he had done at school by his application; indeed, in after-life he would speak of himself as having spent his time at the university very much in the pleasures of society, and—though that must have been an exaggeration—of the bottle. It is certain that the ambition with which he went to Oxford was one capable of being satisfied by a very moderate exercise of good abilities. It was not till after his marriage with Miss Elizabeth Surtees, through which he lost, of course, his fellowship, and with it the prospect of church preferment, that he first concentrated his whole energies, with unflagging zeal, on the congenial study of law—to which, throwing theology to the winds, he was now obliged to devote himself. This marriage, indeed, which was celebrated under the most inauspicious circumstances, may be regarded as the turning point in his career towards the great eminence to which he ultimately attained.

Miss Surtees was the eldest daughter of a large family. Her father was Mr Aubone Surtees, banker, Newcastle; her mother, a daughter of Mr John Stephenson, of Knaresdale Hall, Northumberland, a gentleman who had accumulated a large fortune as a merchant. John Scott first met her at Sedgefield Church, in the county of Durham; and, though it is not known how they became acquainted, it is certain that they speedily became bound to one another by a strong mutual affection, to the great disgust of the friends of the young lady, who was beautiful, and had several suitors among the young squirearchy of the north. To give her passion for Scott a chance of dying a natural death, she was sent to live with her uncle, Mr Henry Stephenson, with whose family she spent several months in London and at their seat in Berkshire, carefully, but it would appear not successfully, guarded from intercourse with her lover. Repression, however, in love, as in religion, is a bad policy; as for one case in which the proverb holds, "out of sight out of mind," there are ten in which it is true that "absence makes the heart grow fonder." Bessie Surtees returned to Newcastle in the spring or summer of 1772, and on the 18th November of the same year—the hour of night is lost to history—John Scott, with the aid of a ladder and an old friend, carried her off from her father's house in Sandhill. Over the border and away went the future Lord Chancellor and his lady, to Blackshields, in Scotland, where they were married with just money enough to pay their way back to their outraged parents. The fathers of both of the young people were set against their union; Mr Scott being, however, only opposed to its taking place at that time, as the connection in itself was one which he could not but covet for his son. If Mr Surtees could not compare young John Scott, who had not as yet chosen his profession, or developed a single lineament of his future greatness, with any one of the young squirearchy in love with his daughter, old Mr Scott could not fail to see that the marriage at that time was a blight on his son's prospects, depriving him of his fellowship and chance of church preferment. When, after a few days, the young pair returned to Newcastle, the Surtees' connection cut them. Mrs Henry Stephenson, indeed, with whom Mrs John had spent the preceding winter, wrote to Mrs Surtees that she could not think of introducing them to her daughter, her only child, whose pretty face and good fortune, which afterwards won her the status of Countess of Wexborough, made her an object of general attraction, and to whom the example of an elopement condoned could not safely be offered. Fortunately old Mr Scott, like a prudent man and affectionate father, set himself to make the best of a bad matter, and received them kindly, settling on his son L.2000, to bear

interest at 5 per cent. till he received the principal. Lord Campbell (*Life of Lord Eldon*, p. 28) tells a story which, however, he does not profess to believe to be true, to the effect that before this provision was made, a wealthy and childless grocer, taking "compassion on the destitute state of John," offered him half his business, and that the offer would have been accepted had not William interposed, begging his father to send John, wife and all, to Oxford, where he would do for them what he could. To Oxford it is certain they went, where John continued to hold his fellowship for what is called the year of grace given after marriage, and to add to his income by acting as a private tutor. After a time Mr Surtees was induced, through the intercession of his son William, to go through the form of reconciliation with his daughter, on whom he subsequently settled first one thousand pounds, and then another, thus making her provision equal to that enjoyed by young Scott from his father. On the death of his son Edward, Mr Surtees' parental love was quickened by his affliction, and the reconciliation between him and his daughter became total. As for John Scott, his year of grace, fortunately for him, closed without any college living falling vacant; with his fellowship he gave up the church, and turned to the study of law. In 1776 he was called to the bar, to which he ventured at first with the humble ambition of establishing himself as an advocate in his native town, a scheme which his early success led him to abandon, and he soon settled to the practice of his profession in London, and on the Northern Circuit. Thus, at last, was he started, as his relative W. E. Surtees, in the *Sketch* already referred to, remarks, on the high road to the chancellorship, having just escaped becoming a coal-fitter, a country parson, a provincial barrister, and, to credit Lord Campbell's story, a retailer of figs and raisins.

In the autumn of the year in which he was called to the bar his father died (6th November 1776), leaving him a legacy of L.1000 over and above the L.2000 previously settled on him; so that with his own and wife's money he had just enough to live on with a pinch—the condition best suited for developing a man's energies—he was above want, but not so far as ever to lose consciousness of its pressure. He was already an excellent lawyer, having devoted his whole powers since his marriage to qualify himself for his profession. We shall now see how he succeeded.

His success to begin was not very remarkable, to judge from the conflicting evidence on the point, for in his old days he loved to exaggerate the difficulties which he had in early life to surmount. But so far is clear from his brother's correspondence, that he succeeded very well on his first circuit, though not so well as to satisfy him of the safety of attempting a London career. On this point he received various opinions from his advisers,—Mr Heron, a solicitor in Newcastle, being one of the few who entertained no doubt of his success. It is certain that he went the length of taking a house in Newcastle, with the view of establishing himself there, and that he did this after his first circuit. He delayed, however, to leave London; and his prospects there suddenly improving, he assigned the Newcastle house to his brother Henry. Still, being careful to hold Newcastle open as a retreat should London fail him, we find him desiring Henry, in a curious letter quoted by Mr Surtees (p. 42 of the *Sketch*) to give out that the assignation of the house was conditional, and that he retained the right (which was not the fact) to resume the lease whenever he thought fit to remove his establishment to Newcastle,—this misrepresentation (*white lie*, as he calls it in the letter, a species of lie which he often found serviceable) being intended to prevent any other barrister attempting in the meantime to settle in Newcastle. The fib (it is not known whether the affectionate Henry told it)

Scott,
John.

Scott,
John.

was unnecessary. In his second year at the bar his prospects began to brighten. His brother William, who by this time held the Camden professorship of ancient history, and enjoyed an extensive acquaintance with men of eminence in London—he was the friend, among others, of the great Dr Samuel Johnson—was in a position materially to advance his interests. Among his friends was the notorious Bowes of Gbyside, to the patronage of whose house the rise of the Scott family was largely owing. Bowes having contested Newcastle and lost it, presented an election petition against the return of his opponent. Young Scott was retained as junior counsel, and though he lost the petition he did not fail to improve the opportunity which it afforded for displaying his talents. This employment, in the commencement of his second year at the bar, and the dropping in of occasional fees, must have raised his hopes; and with the encouragement to persevere in London which he received from Mr Heron of Newcastle, was probably the cause of his abandoning the scheme of becoming a provincial barrister. But whatever the causes were which inspired his hopes, it is certain they did not continue to sustain them. There followed a year or two of dull drudgery and few fees—and those directly traceable to friends—and he began to be much depressed. It is probable that in 1779 he thought it prudent to avoid the expense of going on his circuit. This disheartening state of matters, however, was not of long continuance, for in 1780 we find him suddenly “buttering his bread for life,” to use the words of a knowing agent who addressed him on the occasion, by his appearance in the case of *Ackroyd v. Smithson*, to which in his old age he used fondly to refer, but of which no more can be said here than that it became a leading case settling a rule of law; and that young Scott, having lost his point in the inferior court, insisted on arguing it, on appeal, against the opinion of his employers, and carried it before Lord Thurlow, whose very favourable consideration he won by the ability that he displayed in his argument. The same year Bowes again retained him in an election petition, and in the year following he greatly increased his reputation by his appearance in the Clitheroe election petition, in which he acted as leading counsel; the seniors having suddenly failed their client, and the junior in the case mistrusting himself, having declined to conduct it on his own responsibility. Scott only got his brief about six o'clock of the morning on which the case came on; but notwithstanding the want of preparation made an excellent appearance. From this time his success was certain. In two years he obtained a silk gown, and was so far cured of the modesty which had led him to aspire to the recordership of Newcastle and a retreat there, that he declined accepting the king's counselship if precedence were given over him to his junior, Mr Erskine, though the latter was the son of a peer and a most accomplished orator. He was now on the high way to fortune. His health in the years of his depression had been but indifferent; he complained much of giddiness and swimming in the head; probably his mode of life was too retired (Mrs Scott's management was very frugal), and there was too little variety in his life of study. But now his constitution strengthened with the demands made upon it; his talents, and power of endurance, and ambition, all expanded together. He enjoyed a considerable practice in the northern part of his circuit, before parliamentary committees, and at the chancery bar, and was in sight of the honours and emoluments of the solicitor and attorney generalships. By 1787 his practice at the Equity bar had so far increased that he was obliged to give up the eastern half of his circuit (which embraced six counties), and attend it only at Lancaster.

Scott was now at that stage of professional progress when lawyers, in order to obtain the highest honours, must become political; and to politics, accordingly, he betook

himself. Shortly after taking the silk gown, he entered Parliament for Lord Weymouth's close borough of Weobley, which Lord Thurlow obtained for him without solicitation. In Parliament he played his cards with great discretion, giving a general and independent support to Pitt. His first parliamentary speeches were directed against Fox's India bill. They were unsuccessful. In one he aimed at being brilliant, and becoming merely laboured and pedantic, was covered with ridicule by Sheridan, from whom he received a lesson which he did not fail to improve. Thereafter, abandoning the affectation of eloquence, he contented himself with good sense; and with being remarkable, in spite of the clumsiness and poverty of his style, for the subtlety of his reasonings and the soundness of his law. In 1788 Pitt found it convenient to confer on him the honour of knighthood and the office of solicitor-general; and in the end of this year, as solicitor-general, he attracted attention by his speeches in support of Pitt's resolutions on the state of the king (George III., who then laboured under a mental malady), and the delegation of his authority. It is said that he drew the regency bill, introduced in 1789,—a bill which was as much calculated to fix on him the hatred of the prince (afterwards George IV.) as to secure him the gratitude of the then king, who recovered before the bill passed into law. In 1793 he advanced to the office of attorney-general, in which it fell to him to conduct the memorable prosecutions for high treason against British sympathisers with French republicanism; among others, against the celebrated Horne Tooke. These prosecutions, in most cases, were no doubt instigated by Sir John Scott, and have been generally condemned as an attempt to pervert the criminal law. They were the most important proceedings, as he himself has said, in which he ever was professionally engaged; but it would be altogether out of place, in this brief memoir, to attempt to give any account of them. He has left on record, in his “Anecdote Book,” a defence of his conduct in regard to them. A full account of the principal trials, and of the various legislative measures for repressing the expressions of popular opinion, for which he was more or less responsible, will be found in Mr Twiss's admirable book, *The Public and Private Life of the Lord-Chancellor Eldon*, and in the more masterly and impartial pages of his life, as written by the Lord Chancellor Campbell. In 1799, the office of Chief-Justice of the Court of Common Pleas falling vacant, Sir John Scott's claim to it was not overlooked; and after seventeen years' service in the Lower House, he entered the House of Peers as Baron Eldon. In February 1801, the ministry of Pitt, to whom Lord Eldon owed his promotion so far, was succeeded by that of Addington, and as part of the new arrangement, the Chief-Justice ascended the woolsack, having, indeed, been one of those who suggested the reconstruction of the cabinet, excluding his old patron, Pitt. The chancellorship was given to him nominally because of his great anti-Catholic zeal. From the peace of Amiens, 1801, till 1804, Lord Eldon appears to have interfered little in politics. In the latter year we find him intriguing to turn out Addington, and restore Pitt to the office of prime minister. George III. was again afflicted with his malady, and the Chancellor used his right of approaching the royal person to conduct a correspondence between him and Pitt, in the course of which delicate work he actually took occasion to recast Pitt's letters, to suit them to the moods of the king. The upshot of the intrigue was, says a writer in the *Law Review*, xi. p. 264, that Mr Pitt shoved Mr Addington out of his place, which he himself took, and retained his coadjutor in the business as chancellor, “his ally, within the besieged garrison, who opened the gate to him under the cloud of night, while the rest slept.” There is but one word by which to denominate his conduct on this occasion—treachery. But the

Scott,
John.

Scott,
John.

worst of it is, that he has put on record in his autobiography—"The Anecdote Book," already mentioned—an account of his part in the intrigue, which is inconsistent with the truth. (Vide *Campbell's Life of Eldon*, p. 166, *et seq.*) The whole transaction is most discreditable to his memory. It is painful, yet amusing, to find him justifying himself to others, by constantly repeating that he was the king's chancellor, and not Addington's—a distinction not known to the constitution—and for which, at any rate, there was but a mere shadow of a foundation in the history of his appointment. It is certain that neither Addington, nor any other minister, would have consented to the appointment of a chancellor who was not to owe him fealty. Lord Eldon was now chancellor under Pitt; but Pitt's new administration was but of short duration. On the 2d February 1806, he sank, under the anxieties of office, and his ministry was succeeded by a coalition, under Lord Granville. The death of Fox, who was the new foreign secretary and leader of the House of Commons, soon however broke up the Granville administration; and in the spring of 1807, Lord Eldon once more, under Lord Liverpool, returned to the woolsack, which, from that time, he continued to occupy for about twenty years, swaying the cabinet, and in all but the name the prime minister of England. It was not till 1827, when the premiership, vacant through the paralysis of Lord Liverpool, fell to Mr Canning, the chief advocate of Roman Catholic emancipation, that Lord Eldon, in the sixty-seventh year of his age, resigned the chancellorship for ever. When, after the two short administrations of Canning and Goderich, it fell to the Duke of Wellington to construct a cabinet, Lord Eldon expected that he would have been included, if not as chancellor, at least in some important office, but he was overlooked, at which he was much chagrined. Notwithstanding that, during his long tenure of office, he was constantly protesting before his God and on his conscience,—the element of the composite character of Moises which fell to his lot became more remarkable in him the older he grew—that he did not covet power, but longed for the retirement of his seat, at Encombe, and the society of his dear "Bessy," we find him again so late as 1835, within three years of his death, in hopes of office under Peel. The desire of it only left him to be replaced by disgust with those friends whom he conceived to have deserted him. He ceased to speak in Parliament in July 1834, but even then, as we know, he had not fully realised the fact that he had survived his influence.

In 1821 Lord Eldon was made an earl by George IV., whom he managed to conciliate, and to turn into an enemy of the Whigs, partly, no doubt, by espousing his cause against his wife (whose advocate he had been in the days of George III., when he used to fête her, and dine, and get drunk with her, at Blackheath), and partly through his well-earned reputation for zeal against the Roman Catholics. No sooner was the prince, whose enmity he had justly incurred, made regent, than Eldon hastened to transfer to him the affection which he had so long nourished for his father. The wife of the son, whom George III. hated, was an injured innocent; but with what Mr Surtees calls his "convenient versatility," the wife of the prospective George IV. immediately became a "d—d ——" In the same year, his brother William, who, since 1798, had filled the office of judge of the High Court of Admiralty—the highest dignity of the courts at Doctors' Commons—was raised to the peerage under the title of Lord Stowell.

It is impossible, in a memoir of the brevity to which the present is restricted, to give any more than the merest outline of a life so prolonged, and remarkable for so much activity as Lord Eldon's. It must suffice to state just one or two of the leading facts about his family, and then to

give a brief review of his character and career. His dear "Bessy," his love for whom is almost the only beautiful feature in his life, died before him, 28th June 1831. By nature she was a simple character, and by habits acquired during the early portion of Lord Eldon's career, almost a recluse. She was dearly loved by her husband and surviving son, both of whom—the one in his will, the other on his deathbed—desired to be buried close to her. Two sons of their love reached maturity; John, grandfather of the present earl, who died in 1805, at the age of thirty-one; and William Henry John, who died in 1832, at the age of thirty-seven. Lord Eldon himself survived almost all his immediate relations. His brother William died in 1836. He himself died, in London, in his eighty-seventh year, 3d January 1838, leaving behind him two daughters, Lady Frances Bankes, and Lady Elizabeth Repton, and his grandson, all of whom were round his deathbed. During the last years of his life he had sunk a good deal from public notice. "But," says his biographer, Lord Campbell, "his death created a considerable sensation. . . . When his remains lay in state in Hamilton Place large numbers of all classes went to see the solemn scene; and when the funeral procession, attended by the carriages of the Princes of the blood, many of the peerage, and all the dignitaries of the law, blackened the way, dense crowds stood uncovered, respectfully gazing at it as it passed." He was buried in a vault which he had constructed in the burying-ground of the chapel of Kingston, in Dorsetshire, by the side of his beloved "Bessie." The fortune which he left behind him exceeded in amount half a million of money, mostly invested in the funds; for, like his brother William, though he bought some land, he preferred "the elegant simplicity of the three per cents" to every other security.

The facts already narrated speak volumes as to the talents of Lord Eldon, his powers of managing men, and great political sagacity. He was no legislator,—his one aim in politics was to keep in office, and maintain things as he found them; and almost the only laws he ever helped to pass were laws for popular coercion. For nearly forty years he fought against every improvement in law, as in the constitution; calling God to witness, on the smallest proposal of reform, that he foresaw from it the downfall of his country. Without any political principles, properly so called, and without interest in or knowledge of foreign affairs, he maintained himself and party in power for an unprecedented period by his great tact, and in virtue of his two great political properties—of zeal against every species of reform, and zeal against the Roman Catholics. And yet, though it is most likely that he was a good Christian, and though certainly he frequently appealed to the Supreme Being, excepting when he resided in the country, he never attended public worship. "Although Dr Johnson," says Campbell, "when dying, had sent him a message to request that he would attend public worship every Sunday, he never was present at public worship in London from the one year's end to the other." And when near his death, and he was talking complacently to Dr Philpotts, Bishop of Exeter, of his past life, and the bishop desired to draw his attention to the merits of the Redeemer, he resented the attempt to disparage his own as a reflection on his public character! Yet this was the man who, through a long life, was the defender of the Church, and its champion against every other class of religionists! To pass from his political to his judicial character, is to shift to ground on which his greatness is universally acknowledged. His judgments, which have received as much praise for their accuracy as abuse for their clumsiness and uncouthness, fill a small library. But though intimately acquainted with every nook and cranny of the English law, he never carried his studies into foreign fields, from which to enrich our legal literature; and it must be added, that against the excel-

Scott,
John.

Scott,
Michael.

lence of his judgments, in too many cases, must be set off the hardships, worse than injustice, that arose from his protracted delays in pronouncing them. A consummate judge and the narrowest of politicians, he was DOUBT on the bench and PROMPTNESS itself in the political arena. For literature, as for art, he had no feeling. What intervals he enjoyed from the cares of office, he filled up with newspapers and the gossip of old cronies. Nor were his intimate associates men of refinement and taste; they were rather good-fellows, who quietly enjoyed a good bottle and joke; he uniformly avoided encounters of wit with his equals. He was all his life a hard drinker, and yet cannot be considered as having been intemperate, for his drink neither hurt his health, disturbed his understanding, nor interfered with the discharge of his duties. He is said to have been parsimonious, and certainly he was quicker to receive than to reciprocate hospitalities; but it is known that he was capable of doing generous and liberal actions; and his mean establishment and mode of life are explained on reference to the retired habits of his wife, and her dislike of company. At the same time it must be mentioned, as looking towards the view that he was miserly, that he never quite forgave his grandson for succeeding to his brother William's lands, without a liferent of them having been given to himself. To conclude, his manners were very winning and courtly, a merit in him not the less that they often bound to him friends whom he merely made such that he might use them. In the circle of his immediate relatives he is said to have always been irresistible, nor can it be doubted that he was a far more loveable person to meet with in society than in history. A charming manner in a man of distinguished position, like charity, covers a multitude of sins from the sight of those who have to do with him; but in the distance of time the secondary qualities of a man's nature become indistinguishable, and he falls to be judged of by the broad lineaments of his character and his leading actions. And it is hard for us now, looking back on his life of intrigue and remembering his "convenient versatility" and meannesses, to detect any trace of affection in our admiration for the great Lord-Chancellor. "He is one," says Miss Martineau, "that aftertimes will not venerate; but fortunately for the fame of the larger number of the great ones of the earth, there is a vast neutral ground between veneration and contempt."

As the most appropriate conclusion to this short memoir we append the following account of his person from the pen of Lord Campbell:—"In his person, Lord Eldon was about the middle size, his figure light and athletic, his features regular and handsome, his eye bright and full, his smile remarkably benevolent, and his whole appearance prepossessing. The advance of years rather increased than detracted from these personal advantages." As he sat on the judgment-seat, the deep thought betrayed in his furrowed brow,—the large eyebrows, overhanging eyes that seemed to regard more what was taking place within than around him,—his calmness, that would have assumed a character of sternness but for its perfect placidity,—his dignity, repose, and venerable age, tended at once to win confidence and to inspire respect." (Townsend.) "He had a voice both sweet and deep-toned, and its effect was not injured by his Northumbrian burr, which, though strong, was entirely free from harshness or vulgarity." (J. F. M'L.)

SCOTT, *Michael*, or according to some SIR MICHAEL, was a renowned wizard, once known and feared all over Europe, is supposed to have been one of the Scotts of Balwearie, in Fifeshire, where he is said to have been born in the early part of the thirteenth century, during the reign of Alexander II. After pursuing his studies at home with great success, he went to Paris, and some add to Oxford, where he spent some years in quiet study and meditation. Leaving France he proceeded to the court

Scott,
Michael.

of Frederic the Second of Germany, a prince distinguished for his literary acquirements and for his munificent patronage of literary men. He was strongly addicted to the studies of judicial astrology, alchemy, physiognomy, chemistry, and chiromancy; and seems to have made great progress in those abstruse inquiries during his stay in Germany. Scott is reported to have proceeded to England on the death of his imperial patron in 1250, where he was received with great favour by King Edward I. This portion of the narrative does not hang well together, for Edward I. did not ascend the throne till 1272. From England he is said to have proceeded to Scotland, where he remained during the rest of his life. He is reported to have been one of the ambassadors sent to bring the Maid of Norway to Scotland on the death of Alexander III., in 1290; but this seems very doubtful. Sir Robert Sibbald, in his *History of Fife and Kinross*, cites from an old indenture of 1294 to show that "Sir Michael Scott of Balwearie" was then still living; and further, he ascribes to the same individual a share in the embassy to Norway for the cession of the Orcades in the fifth year of Robert I., that is, in 1310. The ordinary account assigns his death to 1291, and it is just probable he may have been confounded with another person of the same name. The writer of his life in Knight's English *Cyclopædia* conjectures that the Sir Michael Scott who was engaged in the embassy to Norway in 1310 was a son of the great wizard's. Dempster, who wrote in the beginning of the seventeenth century, did not know, moreover, that the magician was the same person with Sir Michael Scott of Balwearie; but tells us the name Scotus was not that of the astrologer's family, but of his nation (Dempsteri *Historia Ecclesiastica Gent. Scot.* 1627). Tradition, likewise, varies concerning the place of his sepulture. Some contend for Ulme or Holme Cultram, in Cumberland, while the Scottish tradition, which is likely to be the correct one, assigns it to Melrose. It is this tradition which is followed by Sir Walter Scott in his *Lay of the Last Minstrel*, where, in the opening of the wizard's grave, the withdrawing from his cold hand of his "Book of Might" forms so striking an episode in the progress of the ballad. All accounts agree in making his books of magic be buried with him wherever he was interred. Satchells (*Hist. of the Name of Scott*), according to Sir Walter Scott, pretends that in 1629, chancing to be at Burgh under Bowness, in Cumberland, he was shown by a person named Lancelot Scott an extract from the works of Michael Scott, containing the following story:—

"He said the book which he gave me
Was of Sir Michael Scott's historie;
Which history was never yet read through,
Nor never will, for no man dare it do.
He carried me along the castle then,
And showed his written book hanging on an iron pin.
His writing pen did seem to me to be
Of hardened metal, like steel or accumie;
The volume of it did seem so large to me
As the Books of Martyrs and Turks historie.
Then in the church he let me see
A stone where Mr Michael Scott did lie."

Michael Scott, who, from all accounts of him, was a very learned man, seems to have paid the penalty attached to letters during that dark age. He made too much of those conjectural sciences of alchemy, astrology, and chiromancy, but otherwise he was unquestionably a great scholar. He is alluded to by Dante, Boccaccio, and other early Italian writers, as a great magician, and is severely taken to task by Mirandola in his book against astrology. To this day he is remembered in remote parts of the south of Scotland as a wonderful magician, to whom the whole realms of hell lay open, and who divided his power only with the prince of darkness. The fantastic stories told of his wonderful

Scott,
Thomas.

projects would fill a volume. Sir Walter Scott records of him, in a note to his *Lay*, that "in the south of Scotland any work of great labour and antiquity is ascribed either to the agency of Auld Michael, of Sir William Wallace, or of the devil." The works ascribed to Michael Scott are the following:—*Aristotelis Opera Omnia, cum notes*, 2 vols., Ven., 1496; *Avicennam de Animalibus ex Arabico in Latium Transtulit*, no date, according to Mackenzie (see his *Lives of Eminent Scottish Writers*); *Physiognomia et de Hominis Procreatione*, Paris, 1508; *Questio curiosa de natura Solis et Luna*, Strasburg, 1622; *Mensa Philosophica*, Leipzig, 1603. This last work has been translated into English under the title of the "Philosopher's Banquet," by W. B., 1633.

SCOTT, Thomas, an eminent divine of the Church of England, was born on the 16th of February 1747. His father was a grazier in Lincolnshire, in humble circumstances, with thirteen children, of whom Thomas was the tenth. The father was ambitious that one of his sons should belong to a learned profession, and with this view sent the subject of this memoir, when about fifteen years of age, to be apprentice to an apothecary and surgeon at Alford. In this situation he conducted himself so improperly, that after a short time he was dismissed by his master, and sent home in disgrace. His father, mortified and vexed by the conduct of his son, treated him with great harshness, and employed him only in the lowest and most laborious drudgery about the farm. For nine years after his return home in disgrace, he was exposed to great hardships, associated with persons in the lowest stations of society, and often joined in their riotous and abandoned pursuits. Conceiving himself used with unjust severity by his father, his temper was soured, and he became exceedingly irritable and discontented. His employment of tending the sheep left him often in solitude. At these seasons his mind was filled with bitter reflections on the past, and gloomy anticipations of the future; and although his education had been very superficial, yet he had acquired so much as awakened in him an insatiable longing after the pleasures and distinctions of literature; and everything conspired to disgust him with his present employment. When about twenty-five years of age, to the astonishment of every one, he declared his resolution of entering the church. This scheme was strongly opposed by his father, treated as chimerical by his friends, and ridiculed by his neighbours. At length, however, his unconquerable fortitude and patient perseverance overcame every obstacle, and he was admitted to priest's orders in the year 1773, and shortly thereafter was appointed curate of Weston Underwood, with a salary of L.50 a year. While here, he applied with indefatigable zeal and industry to the study of sacred and profane literature. His sentiments at first were decidedly Socinian; but a candid and diligent study of the Scriptures gradually opened his eyes to the fallacy and the dangers of the doctrines which he had espoused; and being in the neighbourhood of the old sea-captain, John Newton, the friend of Cowper, who was strongly evangelical and Calvinistic in his views, his acquaintance with that eminent individual may have contributed to this change in his religious sentiments. In the year 1779 he published a small autobiography, entitled the *Force of Truth*, in which he gave a candid statement of the change in his opinions, and the steps by which he was gradually led to adopt the orthodox and evangelical creed. This publication made a great sensation at the time, and has gone through many editions since. In 1780 he succeeded John Newton at Olney, and in 1785 he accepted the situation of lecturer at the Lock Hospital, with a salary of L.80 a year. This, with small sums for occasional lectureships, furnished but a scanty allowance for the support of an increasing family; and when, a few years afterwards, a proposal was made to him by a London book-

seller to write a *Commentary on the Bible*, to be published in numbers, the offer of a guinea a week as remuneration for his writings decided him to engage in the undertaking. This valuable work was well received by the public, and under proper management ought to have been a very profitable speculation; but, owing to the bankruptcy of the bookseller, Scott not only received no remuneration for his labour, but lost all his little savings, and was involved in considerable debt. The first edition, of two thousand copies, commenced in 1802, and was finished in 1809; a second of two thousand copies, in 1807–11; the third of three thousand copies, in six volumes 4to, 1812–14. The fourth was stereotyped, and sold to a great extent. He published a volume of Essays in 1793–94. He also published, in two volumes 8vo, *Remarks on the Bishop of Lincoln's Refutation of Calvinism*; and *Sermons* on various subjects, from time to time. His *Theological Works* were collected and edited by his son, the Rev. John Scott, and published in ten volumes 8vo, in 1823.

In 1803 he left London for the rectory of Aston, Sandford, where he died on the 16th of April 1821. He was a man of eminent piety, somewhat eager and impetuous, but of great sincerity, and sterling honesty of character; of a vigorous intellect, indefatigably diligent in his studies, and a useful and practical preacher.

SCOTT, Sir Walter, was born at Edinburgh on the 15th of August 1771. "My birth," says he, "was neither distinguished nor sordid. According to the prejudices of my country, it was esteemed *gentle*, as I was connected, though remotely, with ancient families, both by my father's and mother's side." His paternal great-grandfather was a cadet of the border family of Harden, which has been ennobled within the last few years, and sprung in the fourteenth century from the great house of Buccleuch; his grandfather became a farmer in Roxburghshire, and married a lady who was a relation of his own; and his father, Walter Scott, was a writer to the signet in the Scottish capital. The poet's mother, Anne Rutheford, who was likewise of honourable descent, was the daughter of one of the medical professors in the University of Edinburgh.

Neither Scott's poetical turn nor his extraordinary powers of memory seem to have been inherited from either of his parents. His early years displayed as little precocity of talent as did the steady development of his mind in ripper days; and the eventful tenor of his childhood and youth, although their impressions can now be traced vividly in his works, must have seemed, but for these, as little calculated as possible to awaken in his mind a love of the imaginative or romantic.

Delicacy of constitution, accompanied by a lameness which proved permanent, exhibited itself before he had completed his second year, and caused soon afterwards his removal to the country. There, at his grandfather's farmhouse of Sandyknowe, situated beneath the crags of a ruined baronial tower, and overlooking a tract of many miles studded with spots famous in border-history, the poet passed his childhood till about his eighth year, with scarcely any interruption but that of a year spent at Bath. From this early period there are related some interesting anecdotes of his sympathy with the grandeur and beauty of nature. The tenacity of his infantine recollections gave promise of what was afterwards so remarkable a faculty in his mind; and the ballads and legends, which were recited to him amidst the scenes in which their events were laid, co-operated in after-days with family and national pride to decide the bent of the border-minstrel's fancy.

His health being partially confirmed, he was recalled home; and from the end of 1779 until 1783 his education was conducted in the High School of Edinburgh, with the assistance of a tutor resident in his father's house. In the years immediately preceding this change, he had shown

Scott,
Sir Walter.

Scott, Sir
Walter.

decided activity of intellect, and strong symptoms of its diversion towards literary pursuits; but now, introduced with imperfect preparation into a large and thoroughly trained class, and thrown, for the first time in his life, among a crowd of boisterous boys, his childish zeal for learning seems to have been quenched by ambition of another kind. His memory, it is true, was still remarkable, and procured for him from his master the title of historian of the class; while he produced some school-verses, both translated and original, which were at least creditable for a boy of twelve. Even his intellectual powers, however, were less active in the proper business of the school than in enticing his companions from their tasks by merry jests and little stories; and his place as a scholar scarcely ever rose above mediocrity. But his reputation stood high in the play-ground, where, possessed of unconquerable courage, and painfully eager to defeat the scorn which his physical defects excited, he is described as performing hazardous feats of agility, and as gaining pugilistic trophies over comrades who, that they might have no unfair advantage over the lame boy, fought, like him, lashed face to face on a plank. At home, his tutor, a zealous Presbyterian, initiated him, chiefly by means of conversation, in the facts of Scottish history, political as well as ecclesiastical, though without being able to shake those opinions which the boy had already taken up as an inheritance descending from his Jacobite ancestors; and he pursued with eagerness, at every interval which could be stolen from the watchfulness of his elders, a course of reading utterly miscellaneous and undigested, and embracing much that to most minds would have been either useless or positively injurious. "I left the High School," says he, "with a great quantity of general information, ill arranged, indeed, and collected without system, yet deeply impressed upon my mind, readily assorted by my power of connexion and memory, and gilded, if I may be permitted to say so, by a vivid and active imagination."

His perusal of histories, voyages, and travels, fairy tales, romances, and English poetry, was continued with increasing avidity during a long visit which, in his twelfth year, he paid to his father's sister at the village of Kelso, where, lying beneath a noble plane-tree in an antique garden, and beholding around him one of the most beautiful landscapes in Scotland, the young student read for the first time, with entranced enthusiasm, Percy's *Reliques of Ancient Poetry*. This work, besides the delight which was imparted by the poems it contained, influenced his mind by giving new dignity, in his eyes, to his favourite Scottish ballads, which he had already begun to collect from recitation, and to copy in little volumes, several of which are still preserved at Abbotsford. "To this period, also," he tells us, "I can trace distinctly the awaking of that delightful feeling for the beauties of natural objects, which has never since deserted me. The romantic feelings which I have described as predominating in my mind, naturally rested upon and associated themselves with the grand features of the landscape around me; and the historical incidents or traditional legends connected with many of them gave to my admiration a sort of intense impression of reverence, which at times made my heart feel too big for its bosom. From this time the love of natural beauty, more especially when combined with ancient ruins, or remains of our fathers' piety or splendour, became with me an insatiable passion, which, if circumstances had permitted, I would willingly have gratified by travelling over half the globe."

In November 1783, Scott became a student in the university of Edinburgh, in which, however, he seems to have attended no classes but those of Greek, Latin, and logic, during one session, with those of ethics and universal history at a later period, while preparing for the bar. At college the scholastic part of his education proceeded even more unprofitably than it had previously done. For science, mental,

physical, or mathematical, he displayed no inclination; and in the acquisition of languages, for which he possessed considerable aptitude, he was but partially industrious or successful. Of Greek, as his son-in-law and biographer admits, he had in later life forgotten the very alphabet. He had indeed entered on the study with disadvantages similar to those which had formerly impeded his progress in Latin; he had, as he informs us, petulantly resolved on despising a study in which he found himself inferior to his competitors; and Professor Dalziel, irritated not only by his carelessness, but by an essay in which he maintained that Ariosto was a better poet than Homer, solemnly pronounced of him, "that dunce he was, and dunce would remain." His knowledge of Latin does not appear to have ever extended farther than enabling him to catch loosely the meaning of his author; although we are informed that for some writers in that tongue, especially Lucan, Claudian, and Buchanan, he had in after life a decided predilection. About the time now under review, he also acquired French, Italian, and Spanish, all of which he afterwards read with sufficient ease; and the German language was learned a few years later, but never critically understood.

It was some time between his twelfth and his sixteenth year that his stores of romantic and poetical reading received a vast increase, during a severe illness which long confined him to bed; and one of his schoolfellows has given an interesting account of excursions in the neighbourhood of the city, during this period, when the two youths read poems and romances of knight-errantry, and exercised their invention in composing and relating to each other interminable tales modelled on their favourite books. The vocation of the romance-writer and poet of chivalry was thus already fixed. His health likewise became permanently robust. The sickly boy grew up into a muscular and handsome youth; and the lameness in one leg, which was the sole remnant of his early complaints, was through life no obstacle to his habits of active bodily exertion, or to his love for out-of-door sports and exercise.

The next step in his life did not seem directed towards the goal to which all his favourite studies pointed. His father, a formal though high-spirited and high-principled man, whose manners are accurately described in his son's novel of *Redgauntlet*, designed him for the legal profession; and, although he always looked wishfully forward to his son's embracing the highest department of it, considered it advisable, according to a practice not uncommon in Scotland, that he should be prepared for the bar by an education as an attorney. Accordingly, in May 1786, Scott, then nearly fifteen years old, was articled for five years as an apprentice to his father, in whose chambers he thenceforth continued, for the greater part of every day, to discharge the humble duties of a clerk, until, about the year 1790, he had, with his father's approbation, finally resolved on coming to the bar. Of the amount of the young poet's professional industry during those years of servitude we possess conflicting representations; but many circumstances in his habits, many peculiarities in the knowledge he exhibits incidentally in his works, and perhaps even much of his resolute literary industry, may be safely referred to the period of his apprenticeship, and show satisfactorily that at all events he was not systematically negligent of his duties. Historical and imaginative reading, however, continued to be prosecuted with undiminished ardour; summer excursions into the Highlands introduced him to the scenes, and to more than one of the characters, which afterwards figured in his most successful works; while in the law-classes of the university, as well as in the juvenile debating societies, he formed, or renewed from his school-days, acquaintance with several who became in manhood his cherished friends and his literary advisers. In 1791 the Speculative Society made him acquainted with Mr Jeffrey and those other young

Scott, Sir
Walter.

Scott, Sir
Walter.

men whose subsequent celebrity has been to a small extent reflected on the arena of their early training.

Scott's attempts in poetry had now become more ambitious; for, it is said, about the completion of his fifteenth year, he had composed a poem in four books on the Conquest of Granada, which, however, he almost immediately burned, and no trace of it has been preserved. During some years after this time, we hear of no other literary compositions than essays for the debating societies.

In July 1792, being almost twenty-one years of age, he was called to the bar. Immediately after his first circuit, he commenced that series of "raids," as he playfully called them, or excursions into the secluded border-districts, which in a few years enabled him to amass the materials for his first considerable work. His walks on the boards of the Parliament House, the Westminster Hall of Scotland, if they gained him for a time few professional fees, speedily procured him renown among his fellow-lawyers as a storyteller of high excellence; his father's connections and his own friendships opened for him a ready admission into the best society of the city, in which his cheerful temper and his rich store of anecdotes made him universally popular; and his German studies produced, in 1796, his earliest poetical efforts that were published, namely, the translations of Burger's ballads, *Lenora* and the *Wild Huntsman*. The same year witnessed the disappointment of a long and fondly-cherished hope, by the marriage of a young lady, whose image, notwithstanding, clung to his memory through life, and inspired some of the tenderest strains of his poetry.

In the summer of 1797, however, on a visit to the watering-place of Gilsland, in Cumberland, he became acquainted with Charlotte Margaret Carpenter, a young lady of French birth and parentage, whose mother, the widow of a royalist of Lyons, had escaped to England, and there died, leaving her children to the guardianship of their father's friend the Marquis of Downshire. A mutual attachment ensued; and, after the removal of prudential doubts, which had arisen among the connections on both sides, Scott and Miss Carpenter were married at Carlisle in December of the same year.

The German ballads, which, though they met with very little sale, had been justly praised by a few competent critics, served as the translator's introduction to the then celebrated Matthew Gregory Lewis, who enlisted him as a contributor to his poetical *Tales of Wonder*; and one cannot now but smile to hear of the elation with which the author of *Waverley* at that time contemplated the patronising kindness extended to him by the author of *The Monk*. Early in 1788 was published Scott's translation of Goethe's *Goetz von Berlichingen*, which, through Lewis's assistance, was sold to a London bookseller for twenty-five guineas; but, though favourably criticised, it was received by the public as coldly as the preceding volume. In the summer of 1799, the poet wrote those ballads which he has himself called his "first serious attempts in verse;" the *Glenfinlas*, the *Eve of St John*, and the *Grey Brother*.

After Scott's marriage, several of his summers were spent in a pretty cottage at Lasswade near Edinburgh, where he formed, besides other acquaintances, those of the noble houses of Melville and Buccleuch. The influence of these powerful friends, willingly exerted for one whose society was agreeable, whose birth connected him, though very remotely, with the latter of those titled families, and who in politics was decidedly and actively devoted to the ruling party, procured for him, in the end of the year 1799, his appointment as sheriff-depute of Selkirkshire, an office which imposed very little duty, while it gave him a permanent salary of £300 per annum. His father's death had recently bestowed on him a small patrimony; his wife had an income which was considerable enough to aid him greatly; his practice as a lawyer yielded, though not much, yet more than

barristers of his standing can usually boast of; and, altogether, his situation in life, if not eminent, was at least strikingly favourable when compared with that which has fallen to the lot of most literary men. Scott, however, now twenty-eight years of age, had done nothing to found a reputation for him as a man of letters; and there appeared as yet to be but little probability that he should attach himself to literature as a profession, or consider it as any thing more than a relaxation for those leisure hours which were left unoccupied by business and the enjoyments of polite society.

In 1800 and 1801 those hours were employed in the preparation of the *Border Minstrelsy*, the fruit of his childish recollections, and of his youthful rambles and studies. The first two volumes appeared in the beginning of the next year, and the edition, consisting of eight hundred copies, was sold off before its close. This work, however, the earliest of his which can be said to have given him any general fame, yielded him about eighty pounds of clear profit; being very far less than he must have expended in the investigations out of which it sprang. In 1803 it was completed by the publication of the third volume. Besides the value which the *Minstrelsy* possesses in itself, in the noble antique ballads, so industriously, tastefully, and yet conscientiously edited, in the curious and spicily-used information which overflows through all the prose annotations, and in those few original poems which gave the earliest warning of that genius which as yet had lurked unseen, the work has now a separate value and interest, as forming the most curious of all illustrations for the history of its editor's mind and of his subsequent works. "One of the critics of that day," remarks Mr Lockhart, "said that the book contained 'the elements of a hundred historical romances;' and this critic was a prophetic one. No person who has not gone through its volumes for the express purpose of comparing their contents with his great original works, can have formed a conception of the endless variety of incidents and images, now expanded and emblazoned by his mature art, of which the first hints may be found either in the text of those primitive ballads, or in the notes which the happy rambles of his youth had gathered together for their illustration."

But before the publication of the *Border Minstrelsy*, the poet had begun to attempt a higher flight. "In the third volume," says he, writing to his friend George Ellis in 1803, "I intend to publish a long poem of my own. It will be a kind of romance of border chivalry, in a light-horseman sort of stanza." This border romance was the *Lay of the Last Minstrel*, which, however, soon extended in plan and dimensions, and, originating as a ballad on a goblin story, became at length a long and varied poem. The first draught of it, in its present shape, was written in the autumn of 1802, and the whole history of its progress has been delightfully told by the author himself, and is well illustrated by his biographer.

In 1803, during a visit to London, Scott, already familiarly acquainted with Ellis, Heber, and other literary men, and now possessing high reputation himself in virtue of the *Minstrelsy*, was introduced to several of the first men of the time; and thenceforth, bland as he was in manner, and kind in heart, indefatigable and successful in his study of human character, and always willing to receive with cordiality the strangers whom his waxing fame brought about him, it is not surprising to find, that not to know personally Walter Scott, argued one's self unknown. The toleration and kindness of his character are illustrated by the fact, that firm as his own political opinions were, and violently as excitement sometimes led him to express them, not only did he always continue on friendly terms with the chief men of the opposite party in Edinburgh, but several of them were his intimate friends and associates; and he even was for some years an occasional contributor to the *Edinburgh Review*.

In 1804 was published his edition of the ancient poem

Scott, Sir
Walter.

Scott, Sir
Walter.

of Sir Tristrem, so valuable for its learned dissertations, and for that admirable imitation of the antique which appears as a continuation of the early minstrel's work.

During that year and the preceding, the Lay was freely communicated to all the author's friends, Wordsworth and Jeffrey among the rest; and after undergoing various changes, and receiving enthusiastic approval in several quarters from which commendation was wont to issue but sparingly, it was at length published, in the first week of 1805. The poet, now thirty-three years of age, took his place at once as a classic in English literature. Its circulation immediately became immense, and has since exceeded that of any other English poem.

But exactly at this culminating point of the poet's life, we must turn aside from the narrative of his literary triumphs, to notice a step of another kind, which proved the most important he ever took. In one of those interesting communications of 1830, which throw so much light on his personal history, he has told us, that from the moment when it became certain that literature was to form the principal employment of his days, he determined that it should at least not constitute a necessary source of his income. Few literary men, perhaps, have not nourished a wish of this sort; but very few indeed have possessed, like Scott, the means of converting the desire into an effectual resolution. In 1805, as his biographer tells us, he was, "independently of practice at the bar and of literary profits, in possession of a fixed revenue of nearly, if not quite, £1000 a year." To most men of letters this income would have appeared affluence; but Scott has frankly avowed, that he did not think it such. The truth is, that his mind was already filled with the feeling which speedily became its master-passion, namely, the ambition, not of founding a new family (for that was too mean an aim for his pride of birth to stoop to), but of adding to his own ancestral pretensions that claim to respect which ancient pedigree does not always possess when it stands alone, but which belongs to it beyond challenge when it is united with territorial possessions. The fame of a great poet, now within his reach, if not already grasped, seemed to him a little thing, compared with the dignity of a well-descended and wealthy Scottish landholder; and, while neither he nor his friends could yet have foreseen the immensity of those resources which his genius was afterwards to place at his disposal for the attainment of his favourite wish, two plans occurred and were executed, which promised to conduct him far at least towards the goal.

The first of these was the obtaining of one of the principal clerkships in the Scottish Court of Session, offices of high respectability, executed at a moderate cost of time and trouble, and remunerated at that time by an income of about £800 a year, which was afterwards increased to £1300. This object was attained early in 1806, through his ministerial influence, aided by the consideration paid to his talents; although, owing to a private arrangement with his predecessor, he did not receive any part of the emoluments till six years later.

The second plan was of a different sort, being in fact a commercial speculation. James Ballantyne, a schoolfellow of Scott, a man possessing a good education, and considerable literary talent of a practical kind, having become the editor and printer of a newspaper in Kelso, had been employed to print the *Minstrelsy*, and acquired great reputation by the elegance with which that work was produced. Soon afterwards, in pursuance of Scott's advice, he removed to Edinburgh, where, under the patronage of the poet and his friends, and assisted by his own character and skill, his printing business accumulated to an extent which his capital, even with pecuniary aid from Scott, proved inadequate to sustain. An application for a new loan was met by a refusal, accompanied, however, by a proposal, that Scott

should make a large advance, on condition of being admitted as a partner in the firm, to the amount of a third share. Accordingly, in May 1805, Walter Scott became regularly a partner of the printing-house of James Ballantyne and Company, though the fact remained for the public, and for all his friends but one, a profound secret. "The forming of this commercial connexion was," says his son-in-law, "one of the most important steps in Scott's life. He continued bound by it during twenty years, and its influence on his literary exertions and his worldly fortunes was productive of much good and not a little evil. Its effects were in truth so mixed and balanced during the vicissitudes of a long and vigorous career, that I at this moment doubt whether it ought, on the whole, to be considered with more of satisfaction or of regret."

From this time we are to view Scott as incessantly engaged in that memorable course of literary industry whose toils advancing years served only to augment, and from which neither the duties of his two professional offices of clerk of session and sheriff, nor the increasing claims made on him by society, were ever able to divert him. He now stood deservedly high in the favour of the booksellers, not merely as a poet and man of genius, but as one possessed of an extraordinary mass of information, and of such habits as qualified him eminently for turning his knowledge to account. He was therefore soon embarked in undertakings, not indeed altogether inglorious, but involving an amount of drudgery to which, perhaps, no man of equal original genius has ever condescended. The earliest of these was his edition of Dryden, which, entered upon in 1805, was completed and published in 1808.

But the list of works in which his poetical genius shone forth continued rapidly to increase amidst his multiplicity of other avocations. From the summer of 1804 till that of 1812, the spring and autumnal vacations of the court were spent by him and his family at Ashestiel, a small mansion romantically overhanging the Tweed some miles above Melrose, and rented from one of the poet's kinsmen. In this beautiful retreat, at intervals during twelve months, was chiefly composed the magnificent poem of *Marmion*, which was published in the beginning of 1808. At the same place, likewise, in 1805, were composed the opening chapters of a novel which, on the disapproval of one of the author's critical friends, was thrown aside and not resumed for years.

Scott's commercial engagements must now again be adverted to. In the year 1808 he took a part, perhaps as suggester, certainly as a zealous promoter, of a scheme which terminated in the establishment of the *Quarterly Review* in London, as a political and literary counterpoise to the *Edinburgh Review*, the advocate of Whig opinions. But the poet had other than political grounds for embarking in this opposition. He had seriously quarrelled with the firm of Constable and Company, the publishers of the *Edinburgh Review*, and of several of his own earlier works; and his wish to check the enterprising head of that house in his attempts to obtain a monopoly of Scottish literature, is openly avowed, in Scott's correspondence at the time, as one of his principal motives for framing another scheme. His plan, as far as it was explained either to the public or to his own friends, amounted only to this: That a new publishing house should be set up in Edinburgh, under the management of John Ballantyne, a younger brother of James; and that this firm, with the acknowledged patronage of Scott and his friends, should engage in a series of extensive literary undertakings, including, amongst others, the annual publication of a historical and literary Register, conducted on Tory principles. But, unfortunately both for Scott's peace of mind, and ultimately also for his worldly fortunes, there was here, as in his previously-formed connection with the same family, an undivulged secret. The profits of the printing-house had been large; Scott's territorial ambition had been

Scott, Sir
Walter.

Scott, Sir
Walter.

growing faster than his prospect of being able to feed it; and these causes, inextricably mixed up with pique towards Constable, and kindness for his Kelso protégés, led him into an entanglement which at length ruined both himself and his associates. By the contract of the publishing house of John Ballantyne and Company, executed in May 1808, Scott became a secret partner to the extent of one third. The unhappy issue of this affair will force itself on our notice at a later stage.

In the mean time we see him prosecuting for some time his career of poetical success. The *Lady of the Lake*, published in 1810, was followed by the *Vision of Don Roderick* in 1811; by *Rokeby* in 1812; and by the *Bridal of Triermain*, which came out anonymously in 1813. His poems may be said to have closed in 1815 with the *Lord of the Isles* and the *Field of Waterloo*; since *Harold the Dauntless*, in 1817, appeared without the writer's name, and the dramatic poems of 1822 and 1830 are quite unworthy of him. In the midst of these poetical employments he made his second and last great appearance as an editor and commentator of English classics, by publishing in 1814 his edition of *Swift*.

But from 1815 till 1825, Scott's name ceased almost entirely to be before the public as an avowed author; and for those who chose to believe that he was not the writer of the *Waverley Novels* it must have been a question not a little puzzling, if it ever occurred to them, how this man, who wrote with such ease, and seemed to take such pleasure in writing, was now occupying his hours of leisure. A few articles in the *Quarterly Review*, such works as *Paul's Letters*, and annotations in occasional editions of ancient tracts, accounted but poorly for his time during ten years.

About 1813 and 1814 his popularity as a poet was sensibly on the decline, partly from causes inherent in his later poems themselves, and partly from extraneous causes, among which a prominent place belongs to the appearance of *Byron*. No man was more quicksighted than Scott in perceiving the ebb of popular favour; and no man better prepared to meet the reverse with firmness. He put in serious execution a threat which he had playfully uttered to one of his own family even before the publication of the *Lady of the Lake*. "If I fail now," said he, "I will write prose for life." And in writing prose his genius discovered, on its first attempt, a field in which it earned triumphs even more splendid than its early ones in the domain of poetry.

The chapters of fiction begun at *Ashestiel* in 1805, which had already been resumed and again thrown aside, were once more taken up, and the work was finished with miraculous rapidity; the second and third volumes having been written during the afternoons of three summer weeks in 1814. The novel appeared in July of that year, under the title of *Waverley*, and its success from the first was unequivocal and unparalleled. Although we cannot here give a catalogue of Scott's works, yet in truth such a list of the novels and romances does in itself present the most surprising proof, both of his patient industry, and of the singularly equable command which he had at all times over his mental resources. In the midst of occupations which would have taken away all leisure from other men, the press poured forth volume after volume, in a succession so rapid as to deprive of some part of its absurdity one of the absurd suppositions of the day, namely, that more persons than one were concerned in the novels. *Guy Mannering*, the second of the series, in 1815, was followed in 1816 by the *Antiquary* and the *First Series of the Tales of My Landlord*. *Rob Roy* appeared in 1817; the *Second Series of the Tales* in 1818; and in 1819 the *Third Series* and *Ivanhoe*. Two romances a-year now seemed to be expected as the due of the public. The year 1820 gave them the *Monastery* and the *Abbot*; 1821, *Kenilworth* and the *Pirate* the *Fortunes of Nigel*,

coming out alone in 1822, was followed in 1823 by no fewer than three works of fiction, *Peveril of the Peak*, *Quentin Durward*, and *St Ronan's Well*; and the comparatively scanty number of novels in 1824 and 1825, which produced respectively only *Redgauntlet* and the *Tales of the Crusaders*, is accounted for by the fact that the author was engaged in preparing a large historical work.

It is impossible even to touch on the many interesting details which Scott's personal history presents during these brilliant years; but it is indispensable to say, that his dream of territorial acquisition was realized with a splendour which, a few years before, he himself could not have hoped for. The first step was taken in 1811, by the purchase of a small farm of a hundred acres on the banks of the *Tweed*, which received the name of *Abbotsford*, and in a few years grew, by new purchases, into a large estate. The modest dwelling first planned on this little manor, with its two spare bed-rooms and its plain appurtenances, expanded itself in like manner with its master's waxing means of expenditure, till it had become that baronial castle which we now reverentially visit as the minstrel's home. The hospitality of the poet increased with his seeming prosperity; his mornings were dedicated to composition, and his evenings to society; and from the date of his baronetcy in 1820 to the final catastrophe in 1826, no mansion in Europe, of poet or of nobleman, could boast such a succession of guests illustrious for rank or talent, as those who sat at Sir Walter Scott's board, and departed proud of having been so honoured. His family meanwhile grew up around him; his eldest son and daughter married; most of his early friends continued to stand by his side; and few that saw the poet in 1825, a hale and seemingly happy man of fifty-four, could have guessed that there remained for him only a few more years (years of mortification and of sorrow), before he should sink into the grave, struck down by internal calamity, not by the gentle hand of time.

And yet not only was this the issue, but, even in the hour of his greatest seeming prosperity, Scott had again and again been secretly struggling against some of the most alarming anxieties. On details as to his unfortunate commercial engagements we cannot here enter. It is enough to say, that the printing company of which he was a partner, which seems to have had considerable liabilities even before the establishment of the publishing house, was now inextricably entangled with the concerns of the latter, many of whose largest speculations had been completely unsuccessful; that, besides this, both firms were involved to an enormous extent with the house of *Constable*; and that large sums, which had been drawn by Sir Walter as copyright-money for the novels, had been paid in bills which were still current, and threatening to come back on him.

In the beginning of 1826, *Constable's* house stopped payment; and the failure of the firm of *Ballantyne*, for a very large sum, followed instantly and of course. Probably even the utter ruin which this catastrophe brought upon Scott, was not more painful to him than the exposure which it necessarily involved, of those secret connections, the existence of which even his most confidential friends could till now have at most only suspected. But if he had been imprudent, he was both courageous and honourable; and in no period of his life does he appear to such advantage, as when he stood, as now, beggared, humbled, and covered with a load of debt from which no human exertions seemed able to relieve him. He came forward without a day's delay, and refused to be dealt with as an ordinary bankrupt, or to avail himself of those steps which would have set him free from the claims of his creditors, on surrendering his property to them. He insisted that these claims should, so far as regarded him, be still allowed to subsist; and he pledged himself that the labour of his future life should be unremittingly devoted to the discharge of them. He did

Scott, Sir
Walter.

Scott, Sir
Walter.

more than fulfil his noble promise; for the gigantic toil to which, during years after this, he submitted, was the immediate cause that shortened his life. His self-sacrifice, however, effected astonishingly much towards the purpose which it was designed to serve. Between January 1826 and January 1828, he had realized for the creditors the surprising sum of nearly L.40,000; and soon after his death the principal of the whole Ballantyne debt was paid up by his executors.

We have now briefly to describe the efforts by which this result was accomplished. After spending at Abbotsford, in 1826, a solitary summer, very unlike its former scenes of splendour, Scott, returning to town for his winter duties, and compelled to leave behind him his dying wife (who survived but till the spring), took up his residence in lodgings, and there continued that system of incessant and redoubled labour which he had already maintained for months, and maintained afterwards till it killed him. Woodstock, published in 1826, had been written during the crisis of his distresses; and the next fruit of his toil was the *Life of Napoleon*, which, commenced before the catastrophe, appeared in 1827, and was followed by the First Series of *Chronicles of the Canongate*; while to these again succeeded, in the end of the same year, the First Series of the *Tales of a Grandfather*. The year 1828 produced the Second Series of both of these works; 1829 gave Anne of Geierstein, the first volume of a *History of Scotland* for Lardner's *Cyclopædia*, and the Third Series of the *Tales of a Grandfather*. The same year also witnessed the commencement of that annotated publication of the collected novels, which, together with the similar edition of the poetical works, was so powerful an instrument in effecting Scott's purpose of pecuniary disentanglement. In 1830 came two Dramas, the *Letters on Demonology*, the Fourth Series of the *Tales of a Grandfather*, and the second volume of the *History of Scotland*. If we are disappointed when we compare most of these works with the productions of younger and happier days, our criticism will be disarmed by a recollection of the honourable end which the later works promoted; and as to the last productions of the mighty master, the volumes of 1831, containing *Count Robert and Castle Dangerous*, no one who is acquainted with the melancholy circumstances under which these were composed and published, will be capable of any feeling but that of compassionate respect.

The dejection which it was impossible for Scott not to feel in commencing his self-imposed task, was materially lightened, and his health invigorated, by an excursion to London and Paris in the course of 1826, for the purpose of collecting materials for the *Life of Napoleon*. In 1829 alarming symptoms appeared, and were followed by a paralytic attack in February 1830, after which the tokens of the disease were always more or less perceptible to his family; but the severity of his tasks continued unremitted, although in that year he retired from his clerkship, and took up his permanent residence at Abbotsford. The mind was now but too evidently shaken, as well as the body; and the diary which he kept contains, about and after this time, melancholy misgivings of his own upon this subject. In April 1831 he had the most severe shock of his disease that had yet attacked him; and having been at length persuaded to abandon literary exertion, he left Abbotsford in September of that year, on his way to the Continent, no country of which he had ever yet visited, except some parts of France and Flanders. This new tour was undertaken with the faint hope that abstinence from mental labour might for a time avert the impending blow. A ship of war, furnished for the purpose by the Admiralty, conveyed Sir Walter, first to Malta, and then to Naples; and the accounts which we have, both of the voyage and of his residence in Italy, abound with circumstances of melancholy interest. After the beginning

of May 1832, his mind was completely overthrown; his nervous impatience forced his companions to hurry him homeward from Rome through the Tyrol to Frankfort; in June they arrived in London, whence Sir Walter was conveyed by sea to Edinburgh; and, having reached Abbotsford on the 11th of July, he there continued to exist, with few intervals of consciousness, till the afternoon of the 21st of September, when he expired, having just completed the sixty-first year of his age. On the 26th he was buried in the beautiful ruins of Dryburgh Abbey.

In the article ROMANCE, observations have been made on Scott's prose works of fiction. It remains here to add a very few words on the character of his poetry. It would be rash for any who have lived only in the same age with a great poet, and still more rash for those whose earliest conceptions of poetical celebrity and poetical beauty are inseparably associated with his name and his writings, to pronounce peremptorily on the rank which may probably be assigned to him by posterity, among the classics of his native language. But without venturing on such ground as this, there are points of comparison with himself and others, which may warrantably be applied to the illustration of his genius.

In regard to the spirit which animates the poetry of Scott, he stands entirely alone in his age; separated indeed so far from the tendencies of the time, that his universal popularity seems at the first glance to have in it something unaccountable. The passionate intenseness and moody self-inquisition of Byron, the calm thoughtfulness and universal sympathies of Wordsworth, and the wildness of Coleridge's lyrical dreams, are in their several kinds allied to those impulses which have widest sway in these generations of our race; while other poets, Campbell with his gentle pathos, Crabbe with his melancholy anatomy of life, and Moore with his overflow of voluptuous imagery, appeal to emotions which are not so much distinctive of particular periods in the history of mankind, as common to the mind in all its ages. But the world which Scott reproduced in the midst of us, the world of feudalism and chivalry, the transition-stage in the annals of Christian Europe, is one with which the men of modern times have very little communion or fellow-feeling; and the boldness with which he chose his themes was even exceeded by that of the tone in which he ventured to treat them; neither jesting with his own fancies, like Pulci or Ariosto, nor, like Tasso, overlaying the essential substance of the chivalrous life with a garniture of poetry and of delicate feeling which left the genuine light of elder times but few openings to glimmer through; but grappling with his materials in the believing and lofty devotion of an historical poet, and painting for us a picture in which the fierce and fiery spirit of martial adventure inspires the leading groups, and gives the outlines of the piece, while interesting local superstitions and the ascetic religion of Catholicism, the absorbing love of country and the anomalous devotedness of feudalism, form, singly or united, the colouring which is spread over different portions of the composition.

For, in essentials, this character of historical truth does belong to Scott; not indeed that his view of the old world is one which could have presented itself to those who lived nearer to the times he depicts; but that it is almost as near to truth as consists with the united requirements made by the purposes of his art and the temper of his age, and probably nearer to the truth than any similar attempt which has been made in modern times. Doubtless there are many instances in which he does not preserve this fidelity to the claims of his subject; but it is surprisingly preserved in his best works, and the inferiority of the others is in no small degree owing to their deficiency in it. Indeed he goes even farther than this; for he not only presents to us the scenes of old, but he invests them in a dress

Scott, Sir
Walter.

Scott, Sir
Walter.

substantially the same as that in which they would have been clothed by poets contemporary, or nearly succeeding them, if these, for their metrical romances or their ballads of love and war, had possessed equal appliances, in a formed language, and in extended views as to the principles of the poetical art.

The Lay of the Last Minstrel is really a long border-ballad; and, inspired by the poet's early recollections and studies, and nourished not only by those copious sources of illustration of which the Border Minstrelsy furnishes abundant specimens, but by affectionate familiarity with the landscapes of his story, this work possesses, both in spirit and in details, at once a fervour and a unity superior to any of his others. Very little indeed, either of incident or character, would require to be withdrawn from it, as foreign to its essence. Marmion is pitched in another key, but is still antique, and, though less rich in characteristic details of the olden time, and rather less free from modern admixtures, is pervaded almost throughout by the chivalrous spirit, while that spirit blazes forth at several points with a splendour which the poet elsewhere never equalled. The poem is a metrical romance of history; the full development of a species of composition in which Barbour had but faintly traced the design. The Lady of the Lake cannot be so readily referred to any one class of our old national poems; in which, indeed, that moving panorama of gorgeous landscapes, amidst which the personages exist, is, as a prominent feature, quite unknown. But this very feature, and the placidly romantic air which breathes through most of the adventures, at once determine its type as a kind of pastoral romance (instanced more frequently in foreign literature than in our own), and diffuse over the work a singular charm, which hides from us much vagueness, both in the characters and in the historical details of manners and ideas. Rokeby, the next in the list, is confessedly the weakest of its author's larger poems, as it is also that in which he has removed himself farthest from his ordinary models. Defective alike in unity of spirit and in historical fidelity, it would, but for some poetical gems which sparkle through, deserve no higher name than that of a novel in verse. In the Lord of the Isles we behold a return to the poet's higher sources of inspiration; for we have here another metrical chronicle, a second Marmion, every way inferior to the first.

It is abundantly evident that the task which Scott has thus performed, of creating anew the scenes and characters of a fierce and chaotic stage of society, allowed him ample room for arousing some of the strongest emotions which poetry can awaken. Sometimes, indeed, he errs by applying himself to the excitement of feelings which, though strictly within his limits, are not broadly enough impressed on the minds of most men to found any lively sympathy. Such are the feelings of superstitious awe and delight in supernatural invention, feelings which are chiefly addressed in his two anonymous poems, and to whose prevalence these works, equal in some points to any thing in verse he ever wrote, mainly owe their want of general interest and popularity. But he far oftener throws himself on those principles which are universally sympathized with and appreciated, not indeed arousing all of them with equal skill, but compounding, out of the use he makes of all, a representation which is at once sufficiently true and widely attractive. That which was really the master-feeling of the times he delineates, the love of warlike adventure, is the path in which he has been by far most successful. In tenderness or passion he does not stand by any means first among the poets of our day; and even in those exhibitions of chivalrous generosity and lofty feeling which are so closely consonant to his stories and their actors, he is, although often delightfully felicitous, yet by no means without his equals; but there is no poet of our times, and very few in any age or coun-

try, who have portrayed with such admirable force and fire the soldier's thirst for battle, and the headlong fury of the field of slaughter. Throughout all his works there occur bursts of this sort, which would of themselves have placed him high among poets of the class, even though he had never written his noblest passages of warfare, the knightly combat of Fitzjames and Roderick, or the magnificent battle-piece which closes Marmion. His clear and cheerful, yet delicately sketched and poetically elevated descriptions of natural scenery, less strong in their outlines than some poetry of a similar kind, and less vivid in their colouring and chiaroscuro than others, but always pleasing and original, and often far more, may probably be said to be, after their warlike temper, the most distinctive feature of his poems.

If the moral tone of Scott's poetry is not high, it must be at least admitted that it is uniformly inoffensive; and if most passages excite us less violently than those of some other poets, there is none whose works leave on the mind a more pleasing expression of content and hopefulness. Perhaps, in his views of human society, the only thing which can at all jar on the feelings of any, is that tendency to aristocratic hauteur, which, not indeed shrinking from contact with the lower orders, and willingly recognising and esteeming many of their virtues, yet considers them strictly as the dependents of higher men, and is silent on every other relation they can be supposed to hold. This feeling, so palpable both in his poetry and in his romances, is, it must be remarked, quite in keeping as a feature of the times he describes in the former class of writings; and even as an element in modern poetry, there doubtless are, after all, many who will esteem the sentiment a just one.

In skill of execution, as respects both ease of expression and melody of versification, there is in the poems an exceedingly observable progress, not at all corresponding to their respective degrees of real merit. Both in diction and in music there is a very wide distinction between the first few stanzas of the Lay and the most finished passages in Rokeby or the Lord of the Isles. Not less noticeable are the variations in point of poetical ornament, a thing very different from genuine poetical force or beauty. In the Lay, the most poetically conceived of all the works, there are wonderfully few passages of the kind that furnish showy quotations, though those of this class that do occur are of a very high order. Marmion, except in the Introduction, scarcely contains more; the Lady of the Lake possesses such far more abundantly; while Rokeby overflows with couplets poetically sententious; and the Lord of the Isles again returns towards the earlier manner.

There is one point of view in which the poems offer a very interesting subject of consideration, not for their own sake, but in their relation to those more celebrated and certainly higher works which succeeded them. They may be regarded as in some sense preparations, or, in the artist's phrase, studies, for the novels and romances. The field of speculation which is thus presented may furnish some intelligent inquirer with extremely apt materials for illustrating the poet's genius; but the mine is too wealthy to be here so much as opened. It may be remarked, however, that while the latter poems in their spirit approach far nearer to the prose romance than the earlier ones, thus in some degree indicating the operations which were going on in the author's mind, yet it is from the earlier that the romances have derived by far the most plentiful hints and materials. In the slightly sketched personages of the poems we may frequently discover elements which were expanded into the finished characters of the prose works, and this not only in the dignified and poetical, but even in the comic, as one instance of which may be cited the Friar John of Norham as the first outline of Robin Hood's Tuck. In incident, the borrowings from the poems are less direct and

Scott, Sir
Walter.

Scott,
William.

palpable; and the most obvious are the obligations which, both in this and the other particular, the Monastery owes to the Lay, and Ivanhoe to Marmion. The Lady of the Lake, also, both in its scenery and its draughts of Highland character, may be considered as the preface to Waverley.

(W. S.—G.)

SCOTT, *William, Baron Stowell*, was born 17th October 1745, at Heworth, in the county of Durham, whither his mother, being with child, had, a few days before, removed; deeming it prudent, as the Scotch rebels were advancing from Prestonpans, to be confined there rather than in Newcastle. William was the eldest son of Mr William Scott, coal-fitter and merchant, Newcastle, and brother of Lord Eldon; and a short notice of his family circumstances and early education will be found in the preceding memoir of his distinguished brother.

When he was in his sixteenth year, a scholarship for the diocese of Durham became vacant at Corpus Christi College, Oxford, and his father, aware of his great talents, resolved that he should avail himself of his accidental birth in the county of Durham to become a candidate for it. He accordingly proceeded to Oxford, and there, on the 24th February 1761, after an examination, which he passed with great distinction, he won the vacant scholarship. His youthful reputation, both in his native town and at Oxford, having suggested that he should choose the bar for his profession, he next, on the 24th June 1762, when between sixteen and seventeen years old, was entered as a student at the Middle Temple. On the 20th November 1764 he took his bachelor's degree, and on the 13th of the following month was elected a probationary fellow of University College, for his eligibility to which he was again indebted to the accident of having been born in the county of Durham. He was, soon after, also elected by the same society a college tutor; and having now, from his fellowship and tutorship together, a liberal income, from which he could even manage to save somewhat, he hesitated to carry out his original plan of going to the bar, fearing to relinquish the certainty which he possessed for the chances of that precarious profession. In 1767 he took the degree of master of arts, and in May 1772 proceeded to B.C.L. In 1774 he was elected by the members of convocation, after a contest, to the Camden chair of ancient history, from which, about four years afterwards, he delivered a course of lectures, which attracted crowded audiences, and brought him into high and wide reputation. These lectures, which are believed yet to exist in manuscript, he could never be induced to publish, probably because he thought they had received greater praise than they deserved, and was unwilling, by exposing them to closer criticism, to risk the fame they had brought him.

In 1776, his father having died and left him his executor, he resolved on following the profession of an advocate at Doctors' Commons, bitterly regretting that his father's reserve as to his means had delayed him so long from entering on an active career. In the same year he retired from his office of college tutor, still, however, retaining his professorship, and continuing to reside mostly in the university, till after he had taken his degree of D.C.L., which he did in 1779. He was called to the bar on the 11th February 1780, having three months previously (in the thirty-fifth year of his age) been admitted at Doctors' Commons into the Faculty of Advocates. By this time he enjoyed an extensive and intimate acquaintance with many eminent men in the metropolis. It has been mentioned, in the memoir of his brother John, that he took after that phase of Moises, his old master, in which he excelled in lively and brilliant conversation; his wit improved with his learning and knowledge of the world; and what with his "clubbable qualities," and the patronage of his friend, Dr Johnson, to whom he had been introduced, in University College,

VOL. XIX.

Scott,
William.

by their common friend Chambers (afterwards Sir Robert), he already possessed, when he removed to London, a *locus standi* in its most intellectual society. So early, indeed, as 1778 he had been elected, through Johnson's influence, a member of the famous Literary Club.

In 1781 Mr William Scott married Anna Maria, the eldest daughter and coheir of Mr Bagnall of Early Court, in Berkshire, a gentleman of moderate pretension. To some the lady's purse appeared more attractive than her person, but there is no reason for thinking that the marriage proved an unhappy one. At any rate, his experience of the fair sex was such as might have justified him in an easy marriage of convenience. In early life he had loved a Miss Jane Reay, daughter of a townsman of his own, who is said to have reciprocated his affection; but her father, ambitious of a higher alliance for his daughter, objected to their union, and the facile young lady (how unlike the gentle "Bessy" of his brother John) married a man of good estate and family. There is reason to think that William and Jane, in their old age, and when both their married lives were over, retained the old feeling for one another! Mr Surtees says, "She, as well as her early admirer, lived to a very advanced age; and he, when an octogenarian peer, requested, through a common friend, permission to send her an engraving of himself, which had just been published. The request was gracefully acceded to, and the engraving sent. Was not this the romance of real life?" It may be added, such are the fates that regulate marriages! After losing Jane, William Scott went, like a man of sense, and fell in love elsewhere, but with equal bad fortune. He failed with the "fair," says Mr W. E. Surtees (the *Sketch*, p. 29), probably because there was too little of "the devil" in his composition. Be that as it may, he had certainly gone through an experience to teach him to consult his head rather than his heart in his next adventure.

In the spring of 1781 Dr Scott's year of silence expired, and he entered on the practice of his profession, with every guarantee of success. For practice in the ecclesiastical courts he was fitted by his long residence in the university, and familiarity with the rights, interests, difficulties, and dangers of the Church; while, as the son of a merchant and shipowner, educated in a large seaport-town, he brought a knowledge of shipping to aid him in practising in the Courts of Admiralty such as few advocates have ever attained to. His talents and great learning at once brought him a large practice. So early as the spring of 1782 we find him writing that he is "exceedingly oppressed with business." This success soon led to his promotion. In 1783 he was appointed to the office of registrar of the Court of Faculties. In 1788 the Bishop of London appointed him judge of the Consistory Court; and the Archbishop of Canterbury, his vicar-general or official principal. In the same year he was knighted, appointed advocate-general, and admitted a privy councillor. In 1798 he attained the highest dignity in connection with his courts, being appointed judge of the High Court of Admiralty. So early as 1780 Sir William Scott had attempted to enter Parliament for his university, but failed. In 1784 he was elected member for the nomination borough of Downton, but was unseated on petition. He afterwards entered Parliament for the same borough in 1790. He was again returned for the same borough in 1796, and on the retirement of Francis Page, Esq., in 1801, from the representation of Oxford, was gratified by being elected member for his university; and this seat he continued to hold till 1821, when, on the occasion of the coronation of George IV., he entered the House of Peers as Baron Stowell of Stowell Park. He retained his place on the bench till 1828. As a politician, Lord Stowell, like his brother, was an uncompromising Conservative, but, excepting that he appeared to vote in support of his party, he

Scott,
William.

took little or no part in politics in either house. During the earlier years of his parliamentary life—if such it may be called—he never spoke at all; nor was he instrumental in carrying any measures into law, excepting one or two affecting the Established Church, of which he was on all occasions a staunch supporter, regarding himself as representative of the clergy, in his double character of judge of the ecclesiastical courts and member for Oxford.

Lord Stowell was twice married. By his first wife he had four children, of whom two, a son and daughter, died in infancy. His eldest daughter, who survived him, was twice married, first to Colonel T. Townsend, a gentleman of Warwickshire, and next to Viscount Sidmouth. His son, William, destroyed his constitution by intemperate habits, and died at the age of forty, about two months before his father. Lord Stowell's first wife died on the 4th September 1809, and on the 10th of April 1813 he was married to Louisa Katherine, Marchioness Dowager of Shigo (widow of the first Marquis and daughter of Earl Howe), with whom he got acquainted, singularly enough, through the circumstance of his having presided, in the preceding December, at the admiralty sessions at the Old Bailey, on the trial of her son, Lord Shigo, for inveigling some seamen from one of the king's ships to serve on board his yacht. This marriage was a very unhappy one, for the lady at least, a circumstance which was foreshadowed by Lord Eldon, who refused to countenance it by being present at the ceremony. The lady was liberal and generous; Stowell was narrow and parsimonious. Her ladyship, having been for many years of her life the nurse of a sick husband, was weaned from society. Lord Stowell was never so happy as when out shining in society. He went feasting and drinking, and his poor wife miserable at home. To her the marriage was a revelation of meanness under the courtly and polished manner of the man who had won her hand; to him the quiet lady with her liberality was an unpalatable spendthrift and bore. In 1817 she proposed a trip to Paris, being anxious to exhibit that metropolis to a favourite niece. He had no objection. She went thither, and at the same time he himself started for a tour in Switzerland. She took suddenly ill, and died in Amsterdam. He finished his tour, leaving Switzerland a fortnight after he heard of her death.

On the 28th January 1836, Lord Stowell died, in the 91st year of his age. He was unquestionably one of the ablest and most accomplished lawyers that ever sat on a judgment-seat. "There is no one," says W. E. Suttees (*The Sketch*, p. 145), "so ambitious of eccentricity as to deny his judgments excellence of the highest order. The statesman in the admiralty, the moral philosopher in the consistory court, will find his own more appropriate instruction; while the scholar who may turn to the reports of Lord Stowell's decisions in either court, will admire the illimitable felicity of the language on which his judicial thoughts are winged, and acknowledge that his character has been formed on the purest models of ancient and modern elegance." And Lord Brougham, in his notice of Lord Stowell in the *Historical Sketches of Statesmen of the time of George III.*, has paid this tribute to his memory:—"His vast superiority was apparent, when, as from an eminence, he was called to survey the whole field of dispute, and to marshal the variegated facts, disentangle the intricate mazes, and array the conflicting reasons which were calculated to distract and suspend men's judgments. . . . If ever the praise of being luminous could be bestowed upon human composition, it was upon his." Some of his judgments, it has further been said, may be called almost revelations of the law, being expositions of large and intricate questions which had never before been thoroughly investigated, but which he completely cleared up and set

at rest. It lies in the observations already made that he surpassed Lord Eldon in literary talent. His style was as remarkable for polish and crystalline clearness as that of his brother for its clumsiness and obscurity.

But though a great lawyer, he was not a great man. He was a great eater, and, says Mr Suttees, "the feats which he performed with the knife and fork were eclipsed by those which he would afterwards display with the bottle." His habits were slovenly and unclean. "The hand that could pen the neatest of periods was itself often dirty and unwashed; and the mouth which could utter eloquence so graceful, or such playful wit, fed voraciously and selected the most greasy food." Then, again, he was an unquestionable miser. He kept a very mean establishment. Fond as he was of his wine, he would drink less at his own than at other tables. "He could drink any given quantity," as was wittily observed by his brother, Lord Eldon, but was abstemious where he had to pay. The most painful fact that remains to be recorded respecting him is, that when his only son William had formed an attachment that was unexceptionable, he, though it may be said he rolled in riches, would not make him a sufficient allowance to enable him to marry. It has been stated already, that this son died from the effects of intemperate habits; it must now be added, that but for this disappointment the young man might have lived. In despair he plunged into excesses. His father just survived him, and his great wealth was gathered up by collaterals. Perhaps his fondness of poking about London visiting cheap shows, was connected more with his avarice than with his curiosity. Whatever show could be visited for a shilling or less, he visited. After his elevation to the peerage, he was actually seen coming out of a penny show in London—cheap excitement! Like Lord Eldon, though a great friend of the church, he never attended public worship; what had been said of his brother might have been said of him, that he was more properly a buttress of the church than a pillar, for he was never seen inside it. At the same time there is no reason to doubt that he was a good Christian; probably, like many other university men, he had a surfeit of chapels when at college, and shuddered at the thought of again entering one. With all his failings, and notwithstanding his avarice which increased with his years, Lord Stowell must be regarded as having been, after a peculiar sort, a kindly, amiable man. As Lord Eldon is quite a loveable person when he goes into retirement with his "Bessie," so does Lord Stowell force our regards when we consider him as a brother and son. The union of the Scott family was the secret of their rise in life, and the most favourable light under which they can now be regarded is that of their family affections. (J. F. M'L.)

SCOU GAL, HENRY, author of *The Life of God in the Soul of Man*, was born at Salton, in Haddingtonshire, in June 1650, where his father, the immediate predecessor of Bishop Burnet, was rector. Having prosecuted his studies with much distinction at the University of Edinburgh, he was appointed to the chair of philosophy in Aberdeen, on his leaving college. Having taught there for some years, he took orders, and was settled at Auchtermuchty, some twenty miles from Aberdeen. It was in this retirement he wrote the work by which he is now known. This book is marked above others of its class by the earnest spirit of piety which it breathes, and by the purity and elegance of the style in which the thoughts are conveyed. It appeared in 1677 anonymously, the modesty of the author withholding him from prefixing to it his name. Scougal hardly survived its publication a twelvemonth. He died of consumption on the 13th of June 1678, in his twenty-eighth year. He was interred on the north side of the chapel of King's College, Aberdeen, where a tablet of black marble records to the passer-by the revered dust which lies below.

Scougal.

Screw
||
Scribe.

SCREW, one of the six mechanical powers, is a cylinder cut into several concave surfaces, or rather a channel or groove made in a cylinder, by carrying on two spiral planes the whole length of the screw, in such a manner that they may be always equally inclined to the axis of the cylinder in their whole progress, and also inclined to the base of it in the same angle.

SCRIBE, in Hebrew *sepher*, is very common in Scripture, and has several significations. It signifies, *first*, a clerk, writer, or secretary. This was a very considerable employment in the court of the kings of Judah, in which the Scripture often mentions the secretaries as the first officers of the crown. Seraiah was scribe or secretary to King David (2 Sam. viii. 17). Shevah and Shemaiah exercised the same office under this prince (2 Sam. xx. 25). In Solomon's time we find Elihoreph and Ahia secretaries to that sovereign (1 Kings iv. 4); Shebna under Hezekiah (2 Kings xix. 2); and Shaphan under Josiah (2 Kings xxii. 8). As there were but few in those times that could write well, the employment of a scribe or writer was very considerable. *Secondly*, a scribe is put for a commissary or muster-master of an army, who makes the review of the troops, keeps the list or roll, and calls them over. Under the reign of Uzziah, king of Judah, there is found Jeil the scribe, who had under his hand the king's armies (2 Chron. xxvi. 11); and at the time of the captivity, it is said the captain of the guard, among other considerable persons, took the principal scribe of the host, or secretary at war, which mustered the people of the land (2 Kings xxv. 19). *Thirdly*, scribe is put for an able and skilful man, a doctor of the law, a man of learning that understands affairs. Jonathan, David's uncle by the father's side, was a counsellor, a wise man and a scribe (1 Chr. xxvii. 32). Baruch, the disciple and secretary to Jeremiah, is called a scribe (Jer. xxxvi. 26); and Ezra is celebrated as a skilful scribe in the law of his God (Ezra vii. 6). The scribes of the people, who are frequently mentioned in the gospel, were public writers and professed doctors of the law, which they read and explained to the people. Some place the original of the scribes under Moses; but their name does not appear until under the judges. It is said that, in the wars of Barak against Siseia, "out of Machir came down governors, and out of Zebulun they that handle the pen of the writer" (Judges v. 14). But others think that David first instituted them when he established the several classes of the priests and the Levites. The scribes were of the tribe of Levi; and at the time that David is said to have made the regulations in that tribe, we read that six thousand men of them were constituted officers and judges (1 Chr. xxiii. 4), among whom it is reasonable to think that the scribes were included. For in 2 Chr. xxiv. 6, we read of Shemaiah the scribe, one of the Levites; and in Chr. xxxiv. 13, we also find it written, "Of the Levites that were scribes and officers."

The scribes and the doctors of the law, in the Scripture phraseology, mean the same thing. And as the whole religion of the Jews at that time consisted chiefly in pharisaical traditions, and in the use that was made of them to explain the Scripture, the greatest number of the doctors of the law, or of the scribes, were Pharisees; and we almost always find them joined together in Scripture. Each of them valued themselves upon their knowledge of the law, and upon their studying and teaching it (Mat. xxii. 52).

They had the key of knowledge, and sat in Moses's chair Scrimzeor. (Mat. xxiii. 2). Epiphanius, and the author of the Recognitions imputed to St Clement, reckon the scribes among the sects of the Jews; but it is certain that they formed no sect by themselves, and were only distinguished by their study of the law.

SCRIMZEOR, OR SCRIMGEOUR, HENRY, a learned Scotchman of the sixteenth century, was born of an ancient and noble family, at the town of Dundee, in 1506. Passing from the grammar-school of Dundee, where he began his education, he entered the University of St Andrews, and gained much distinction in the study of philosophy. Having removed to Paris, he there prosecuted his inquiries into civil law. The fame of the noted legal lecturers, Baion and Duaren, drew him to Bourges, where he made the acquaintance of Amiot, then Greek professor there, and subsequently cardinal. He now, at the suggestion of his friend Amiot, became tutor to a family named Bucherel, and subsequently went to Italy, in company with Bornetel, the bishop of Rennes, whose friendship he had recently secured. Scrimgeour gained the intimacy of many learned men, and greatly improved himself during this Italian tour. He wrote a life of the famous apostate, Francis Spira, which was probably printed at Basle in 1550 or 1551, but it is not mentioned in any copy of his writings which has come under our notice. On his way home he had occasion to pass through Geneva, where he was prevailed upon to accept of a lectureship in philosophy. Ulric Fugger, the merchant-prince of that age, having invited him to Augsburg, he left Geneva, and gave the rich merchant the benefit of his superior judgment, and his great information in the augmentation of his splendid library. Being introduced by his German patron to Henry Stephens, then residing at Geneva, and the most famous printer in Europe, he entered into negotiations respecting the publication of his works; but, from whatever cause, a jealousy seems to have sprung up between them, which ended only with the life of Scrimgeour. He died at the city of Geneva in or about the year 1571. Scrimgeour's literary property and fame were committed, on his death, to Isaac Casaubon, who seems to have been hardly just to the reputation of the deceased Scotchman. It is now quite impossible to disentangle the writings of Scrimgeour from those of his "literary executor." Casaubon published, in his own name, an edition of Athenæus in 1600, an edition of Strabo in 1602, Diogenes Laertius in 1593, the *Basilica*, Phurnutus and Palæphatus, 1570—in all of which he was much indebted to the annotations of Scrimgeour and to his improvements on the texts of his authors. The only work published with Scrimzeor's name was Justinian's *Novellæ Constitutiones*, which he had translated into Greek in 1558. This learned man left behind him many valuable manuscripts, of Demosthenes, Æschines, Cicero, and Eusebius, carefully collated, but which never yet have been given to the public. Scrimzeor's immense erudition was only equalled by his exquisite judgment, which found an excellent field for its exercise in the errors and obscurities which had crept into those ancient authors on which he delighted to labour. Cujanus used to say of Scrimgeour that he never talked with him without learning something he had not known before. By no means a wonderful saying for an ordinary man, but a very remarkable one for Cujanus.

SCRIPTURE, HOLY.

Scripture. UNDER this title are commonly designated the sacred books of the Jews and the Christians, in which are contained the revelation of God's will to mankind, and the principles of that religion which He has inculcated upon us. In other parts of this work the reader will find articles elucidatory of the claims preferred and of the doctrines taught in these books. (See especially **INSPIRATION, MIRACLE, PROPHECY, and THEOLOGY.**) In the present article it is proposed to furnish an outline of what may be denominated *the historico-critical knowledge of these books*. In treating of this we have to do with the composition, the history, the reputation, and the literary characteristics of the sacred writings viewed simply as remains of ancient literature.

This department of investigation is comparatively of recent date. In the earlier ages of the church the same necessity for such inquiries did not exist as now, in consequence especially of the efforts which have been made in more recent times to impugn the authenticity of the sacred documents; nor is it probable that the early fathers, from the views which they entertained of the sole agency of the Holy Spirit in the composition of these, would have deemed any inquiry into their peculiarities, as the products at the same time of human agency, other than impious and absurd (1). Since the time, however, when Spinoza issued his attack upon the authenticity of the Pentateuch and the general inspiration of the Scriptures (1670), and Richard Simon, a presbyter and fellow of the oratory at Paris, followed with his acute, learned, and liberal investigations into the critical history of the Old Testament (1678), this subject has occupied the attentive study of critics and theologians of all confessions, and may now be said to have reached the dignity of a *science* (2). The path opened by Spinoza was followed by J. S. Semler in Germany, who may be said to have founded the school of neologic criticism in that country. He was succeeded by Eichhorn, Bertholdt, Augusti, and De Wette, in whom the rationalistic and sceptical school culminated (3). On the more orthodox side appeared J. D. Michaelis, Jahn, Hug, and, more recently, Scholz, Schott, Hengstenberg, Havernick, Credner, Feilmoser, Guericke, and others (4). In England, besides the older works of Walton, Mill, and Harwood, the only productions in this department of any value are those of Horne, Davidson, Tregelles, Porter, Westcott, and Scrivener (5).

1. The prevailing notion among the Jews and the early Christians respecting inspiration was, that the faculties of the person inspired were completely suspended and superseded during the afflatus, so that the only parts of him actively engaged in the work of composition were his hands and his eyes. Philo speaks of God as "using the organs of the prophets for the manifestation of His will" (*ἑὸν πανταρχαίου τοῖς ἐκείνων ὄργανοις πρὸς ἀπαγγελίαν ἂν ἐν ἑαυτῷ*, *De Monarch.* lib. i., ed. Mangey, t. ii., p. 222): Justin Martyr compares them to the strings of a lyre, which produce sounds just as they are touched by the hand of the player (*Cohort. ad Græcos*, c. 8); and Augustin frequently speaks of the Scriptures as the "Chirograph of Deity," and of their writers as "the stylus or pen of the Holy Spirit." The influence of such exclusive views in discouraging any inquiries of a historico-critical nature is seen in the following sentence of Gregory the Great:—"Quis librum Job scripserit, valde superflue quaeritur, cum tamen auctor libri Spiritus Sanctus fideliter credatur. Ipse scripsit, qui et in ejus opera inspirator extitit et per scribentis vocem imitandam ad nos facta transmisit." (*Moral in Job*, t. i., p. 7.) Ideas of a similar kind are found in the writings of several of the older divines subsequent to the Reformation. (For the opinions most generally received among Protestant divines in the present day, see Henderson's *Lectures on Inspiration*, London, 1836, 3d ed. 1852; Lee on *Inspiration*.)

2. Spinoza's work is entitled *Tractatus Historico-Politicus, continens Dissertationes aliquot, quibus ostenditur, Libertatem Philosophandi non solum salva pietate et republicæ pace posse concedi; sed eandem nisi cum pace reipublicæ ipsaque pietate tolli non posse*, Hamburgi, 1670, 4to. Simon's *Histoire Critique du Vieux Testament*

appeared in 1 vol. 4to, in 1678, at Paris; but a fuller and more correct edition was published at Rotterdam in 1685, superintended in all probability by the author. It produced numerous replies and strictures, from the pens both of Catholic and Protestant divines, of which the most important were those of Spanheim (*Lettre sur l'Hist. Crit. du V. T. du R. Simon*); Du Pin (*Dissert. prelim. ou Polémiques sur la Bible*), and Le Clerc (*Sentimens de quelques Théologiens d'Hollande sur l'Hist. Crit. du V. T. composée par le D. R. Simon*). Both Du Pin and Le Clerc, but especially the latter, whilst reproving Simon, indulged certain speculations of their own, which were considerably too free for the age in which they lived, and which drew down upon them, along with the object of their strictures, the censures of the acute and ingenious Bossuet (*Divers Traictés, contre Mr R. Simon, Du Pin et autres, Œuvres Posthumes*, t. ii., 1753). By far the ablest reply to Spinoza was furnished by Carpzov (*Introductio ad Libros Canonicos V. T. omnes*, 4to, Lips. 1721, 3d ed. 1741).

3. Semler, *Apparatus ad liberaliorem Vet. Test. Interpretationem*, Halle, 1773; *Abhandlung von Freier untersuch. des Can.*, 1771-75. Eichhorn, *Einführung in das A. T.*, 4th ed. 5 vols., Gott. 1820-24; *In die Apocryphischen Schriften des A. T.*, Leipz. 1795; *In das N. T.*, 5 vols., Leipz. 1804-27. Bertholdt, *Histor. Kritische Einl. in sämtliche Kanonische und Apoc. Schriften des A. und N. T.*, 6 vols., Erlangen, 1812-19. Augusti, *Grundriss einer Hist. Krit. Einl. ins A. T.*, Leipz. 1827, 2d ed.; *Versuch einer Hist. Dogmat. Einl. in die Heilige Schrift*, Leipz. 1832. De Wette, *Lehrbuch der Hist. Krit. Einl. in die Bibel A. und N. T.*, 2 vols., Berlin 1849, 6th ed. (translated by Theodore Parker, 2 vols., Boston, 1848).

4. Michaelis, *Einl. in die Göttl. Schriften des A. Bundes*, 4to, Hamburg, 1784; *In die Göttl. Schriften des N. B.*, 2 bde. 4to, Göttingen, 4th ed. 1788 (translated by Bishop Marsh, in 6 vols. 8vo, with considerable additions, 3d ed., Camb. 1818). Jahn, *Einl. in die Göttl. Bücher des A. Bundes*, 3 vols. 8vo, 2d ed., Wien. 1802-3; *Introductio in Bibl. Sacr. V. T. in epitomen reducta*, ed. 2da, Vien. 1814, 8vo. Hug, *Einl. in die Schriften des N. T.*, 2 vols., 3d ed. Stuttgart and Tübingen, 1827 (translated by the Rev. D. G. Whit, LL.D., 2 vols. 8vo, 1827, and with much greater accuracy by D. Fosdick, junior, Andover, United States, 1837). Scholz, *Einl. in die Heil. Schriften des A. und N. T.*, 2 vols., Coln. 1846. Schott, *Isagoge Hist. Critica in libros N. T. Sacros*, Jenæ, 1830, 8vo. Hengstenberg, *Beiträge zur Einl. ins A. T.*, 3 vols., Berlin, 1831, 1834, 1839 (translated by J. H. Ryland; *Insertions on the Genuineness of the Pentateuch*, 2 vols.; and *On the Genuineness of Daniel and the Integrity of Zechariah*, 1 vol., Edin.) Havernick, *Handbuch der Hist. Krit. Einl. in das A. T.*, 4 parts, Würlingen, 1836-44 (*A General Histor. Crit. Introduction to the O. T.*, translated by W. L. Alexander, D.D., Edin. 1852; *An Histor. Crit. Introd. to the Pentateuch*, translated by A. Thomson, A.M., Edin.) Credner, *Beiträge zur Einl. in die Bibl. Schriften*, 2 vols., Halle, 1838; *Einl. in das N. T.*, 2 parts, Halle, 1836. Feilmoser, *Einl. in die Bücher des N. T.*, Tüb. 1830; Guericke, *Histor. Krit. Einl. ins N. T.*, 1843, of which an improved edition has lately appeared.

5. Walton, *Prolegomena in Biblia Polyglotta*, Lond. 1657, of which a separate edition was published, with a preface by J. A. Dathie, at Leipsic, in 1 vol. 8vo, 1777, and republished, with improvements and additions, by Archdeacon Wrangham, in 2 vols. 8vo, Cambridge, 1828. Mill, *Prolegomena in N. T.*, Oxon. 1707, folio. Harwood, *Introduction to the Study and Knowledge of the New Testament*, 2 vols. 8vo, Lond. 1767-1771. Marsh, *Lectures on the Criticism and Interpretation of the Bible*, Camb. 1828. Horne, *Introduction to the Critical Study and Knowledge of the Holy Scriptures*, 10th edition, revised, corrected, and brought down to the present time, by the Rev. T. H. Horne, B.D., Rev. S. Davidson, D.D., LL.D., and S. Pr. Tregelles, LL.D., 4 vols. 8vo, Lond. 1856. Davidson, *Biblical Criticism*, 2 vols. 8vo, Edin. 1852; *Introduction to the New Testament*, 3 vols. 1848-51. Porter, *Principles of Textual Criticism, with their Application to the Old and New Testaments*, London, 1847. Tregelles, *An Account of the Printed Text of the Greek New Testament, with Remarks on its Revision upon Critical Principles*, &c., London, 1854. Westcott, *History of the Canon of the New Testament*, Camb. 1855; Scrivener, *Supplement to the Authorized Version of the New Testament*, &c., London, 1855; *Full and Exact Collation of about Twenty Greek MSS. of the Holy Gospel, with Critical Introduction*, Camb. 1853. To these may be added Kitto's *Cyclopædia of Biblical Literature*, 2 vols. 8vo, 2d ed.

Many valuable treatises upon separate portions of the general subject are extant in different languages, but these it would be out of place to attempt to enumerate here. (See the *Bibliographical Appendix* to Horne's *Introduction*, Orme's *Bibliotheca Biblica*, and Winer's *Handbuch der Theologischen Literatur*.)

Scripture.

Scripture. This subject divides itself into two parts, a *general* and a *special*,—the former having reference to the sacred volume as a whole, the latter to the separate books of which it is comprised. In the present article we shall confine ourselves to the former of these, and offer a few general observations on the collected Scriptures, as such.

SECT. I.—The Name.

Various designations have been affixed to the sacred volume. As a whole, it bears the name of *The Bible*, τα βιβλία; *Holy Scriptures*, ἱερα γραφή, θεια γραφή, ἄγια γραφή; *Bibliotheca Sancta*. The Jews called their part of it by such terms as עשרים וארבעה, *i.e.*, *Four-and-twenty*, with reference to the number of separate books; כתב or מכתב, *i.e.*, *Writing*, a term borrowed from Exod. xxxii. 16; ספרי הקדש, *i.e.*, *Books of Holiness*; תורה נביאים וכתובים, *i.e.*, *Law, Prophets, and Hagiographa*. In the Apocrypha they are styled ὁ νομος, και οἱ προφηται, και τα ἄλλα πατρια βιβλια, *Jesus Sirac. Proleg. sub. init.* So also in the New Testament, νομος και προφηται, Matt. v. 17; νομος, προφηται, και ψαλμοι, Luke xxiv. 44; frequently ἡ γραφή and αἱ γραφαί; τα ἱερα γραμματα, 2 Tim. iii. 15. At an early period of the Christian era, the term διαθηκη began to be affixed to the Scriptures as the documents unfolding God's *covenant*; and their two great divisions to be designated as ἡ παλαια διαθηκη and ἡ καινη διαθηκη respectively. This usage seems to have been drawn from the language of Paul, 2 Cor. iii. 6 and 14, though it is only in the writings of Origen that it makes its appearance for the first time. The Latins rendered the word διαθηκη by *Testamentum* or *instrumentum* (1), according to its primary meaning, though not that in which it is employed by Paul, who uses it evidently in the sense of *Fœdus*; and from thus we have the appellation employed by almost all the versions of modern Europe (2).

1. Tertull. *Adv. Marc.* iv. 1; Aug. *De Civ. Dei*, xx. 4.

2. Horne's *Introduction*, vol. i., p. 30; Michaelis, *Enleil*, bd. i., s. 1, and in Marsh's translation, vol. 1., p. 1; Augusti, *Grundriss*, p. 16, 2d ed.; De Wette, *Lehrbuch*, p. 7, 6th edition.

SECT. II.—Genuineness and Authenticity of the Sacred Volume.

As ancient literary documents, the Scriptures lay claim to be regarded as both *genuine* and *authentic* or *credible*. A book is *genuine* when it really is what it professes to be, as the composition of a particular individual, or as produced under particular circumstances, and at a certain place and time; as opposed to a book which appears under a *forged* title. A book is *credible* when the statements it contains are physically true; as opposed to a book the contents of which are *false* or *fictitious*. Both these qualities may meet in the same work, or they may exist separately in separate works. Thus the book of Genesis may be the composition of Moses, and yet be fabulous; or it may be true in all its statements, and yet not be the work of Moses; or it may be, as it is generally believed to be, both the production of Moses and true, both genuine and credible.

The genuineness and credibility of the sacred books form matter of separate investigation and proof. At the same time, they are so connected that the proof of the one paves the way for the proof of the other; for, in the case of such works it is highly improbable that truth would be issued under a forged name, or that such men as Moses, Samuel, or the evangelists would or could issue fictitious narratives as true. It is not, however, matter of indifference which of them we establish first. Before we can set ourselves to prove their credibility we must be in circumstances to show their genuineness; for unless we can do this, a preliminary difficulty will lie in the way of the

former, from the suspicion that these books appear with a falsehood, or at least what has not been shown to be a truth, upon their front; a work of supposititious authorship being always *prima facie* less credible than one which is the genuine production of the writer to whom it is ascribed.

The proof of the genuineness of the Sacred Scriptures rests upon the following considerations:—

1. There is no antecedent impossibility that they should be genuine. It cannot be shown that it is impossible for Moses to have written the Pentateuch, Isaiah and the other prophets their prophecies, the evangelists their gospels, the apostles their epistles, or for the books which are anonymous to have been composed under the circumstances which they profess; nor that, being composed, it is impossible for them to have been preserved and handed down from generation to generation.

2. Circumstances were favourable to the preservation of these books, supposing them written. The Old Testament books professedly form the national literature, as well as the sacred documents of the Jews, and would naturally be carefully preserved by them. The New Testament books constitute the religious archives and statute-books of the Christian church, and would from their first publication be sacredly conserved by those for whom they were so deeply interesting.

3. It is matter of undeniable history that both Jews and Christians did possess certain sacred books, which they regarded with the utmost reverence, and preserved with the greatest care. The only question then is, Are the books which we possess the same as those thus revered and preserved? And, *first*, with respect to those of the Old Testament.

i. These are the books which were recognised in the early church as the sacred books of the Jews. This is placed beyond doubt by the early versions of Scripture, and by the catalogues of Athanasius, Epiphanius, Jerome, Origen, and Melito, Bishop of Sardis. (Lardner, Works, vol. iv., p. 290, 8vo ed.)

ii. The books of the Old Testament which we possess must have been extant at the commencement of the Christian era. This is evident from the allusions to them, and the quotations from them, in the New Testament, but especially from the testimony of Philo, an Egyptian Jew, who at the latest was contemporary with the apostles, and also of Josephus, himself a priest of the Jews, and consequently accurately informed on all matters relating to their sacred books, and who lived in the latter part of the first century of the Christian era. Philo gives no formal catalogue, but quotes from or refers to nearly all the books of the Old Testament, while no other is mentioned by him as of accredited authority. Josephus, besides frequent quotations and allusions, gives (*Cont. Apion.*, lib. i., c. 8) a catalogue of the sacred books of his nation, assigning five to Moses, thirteen to the prophets, and four to the writers of hymns and moral maxims. This, if we regard Judges and Ruth as one book, and add the Lamentations to the Prophecies of Jeremiah, which there is good reason to believe was the case in the days of Josephus, gives exactly the number of the books now extant.

Schmidtii *Historia Antiqua et Vindicatio Canonis Sacri Veteris et Novi Testamenti*, pp. 129–189, Lips. 1775; Ejusdem *Enarratio sententiarum Flav. Josephi de libris Vet. Test.*, Wittenberg, 1787; Horne-manni, *Obs. ad Illustrationem Doctrinæ de Canone Vet. Test. ex Philone*, Hauniae, 1778; Henderson's *Lectures on Inspiration*, p. 468, Lond. 1836.

iii. These books must have been written *long before* the Christian era. This is plain from the fact of targums or explanations of them into the Syro-Chaldaic dialect, which was the language of the people, having been made for a long course of years antecedent to the times of Onkelos and Jonathan Ben Uzziel, by whom they were collected

Scripture. in the form now extant, and who lived probably near the days of our Lord; from the allusions to the sacred books of his nation already quoted from the prologue to the work of Jesus the son of Sirach, which was composed about 230 years B.C.; and from the existence of the Septuagint version, which was at least commenced 280 years B.C.

iv. Under such circumstances, the forgery of these books was morally impossible. If such a thing took place, it must have been during the 140 years which elapsed between the death of Malachi, the last of the prophets, and the execution of the Septuagint version. But, first, it is inconceivable that, in so short a period, and in an age when literature was not a trade, a set of men (for the agency of only one man is out of the question) should have appeared in the land of Judea, all endowed with genius sufficient to share in the composition of such works, and all infected with the spirit of literary dishonesty, so as to act the part of forgers. Secondly, even supposing such a piece of deception attempted, it is inconceivable how it should have succeeded, as, by the holders of this hypothesis, it must be allowed to have done. As the whole nation of the Jews acknowledged these books, we must suppose, either that they were all imposed upon in the matter, or that they all agreed to impose upon the rest of the world. But no ingenuity can suffice to persuade a nation that they have for ages possessed sacred books, when they know they have not; and a national agreement to sanction a forgery and tell the world a lie, is a hypothesis too extravagant to be for a moment entertained. Thirdly, the opinions expressed in these books, the doctrines taught, and the duties enjoined, are so averse from those most cherished by the Jews at the time the supposed forgery must have taken place, and the facts recorded are so little flattering, upon the whole, to the pride of the nation, that it is quite incredible, either that any should have been found to write them, or that, being written, they should have been received by the people with any other feelings than those of execration and abhorrence. The respect in which they were held can be accounted for only on the principle that it was rendered to the *venerable antiquity* and *indisputable authority* with which they were invested.

v. The force of this conclusion is heightened by the circumstance, that while all testimony is in favour of the genuineness of these books, not one witness can be produced whose evidence is incompatible with this.

vi. When we apply to the contents of these books such tests as are best fitted to try their genuineness, the result is such as to confirm our previous conclusion. 1. They display just such a diversity of talent, style, and character as we should expect in works composed by different authors at different times. 2. They are written, with a few slight exceptions, in pure Hebrew, a language which we know to have been that of the Jews before the captivity, but the knowledge of which as a vernacular tongue was entirely lost very shortly afterwards. 3. Whilst they use the same language, there are certain grammatical and linguistic differences between the early and the later writers, indicative of such changes as all languages experience in the lapse of time, but less extensive than those found in others of the ancient tongues; which is exactly what might have been expected in the case of persons using, through a long interval, a language which, though exposed to causes of change, was, from the fixed and exclusive habits of those speaking it, less liable to be affected in this way than the languages of more versatile and cosmopolitan nations. 4. The narratives occurring in these books are marked by that minute accuracy and circumstantiality of detail which a forger generally endeavours to avoid, but into which a true witness naturally falls, from having all these details present to his mind as integral parts of the occurrence which he attests, *as it presented itself to his senses*. 5. There

is, amidst the greatest elevation of thought and sublimity of conception, a chastened simplicity of language, and, amidst the utmost variety of manner, style, and illustration, an essential unity of doctrine, which comports well with the claims of these books to be regarded as the sacred books of the Jews, and seems strongly incompatible with the supposition that they are forgeries.

For these reasons, it is affirmed that the books which we now possess are the same as those which were always possessed and held genuine by the Jews. We turn, *secondly*, to the New Testament, and inquire whether the same evidence of its genuineness can be furnished.

i. No person doubts the existence of the New Testament books from the close of the *fourth* century of the Christian era downwards, because the fact is so notorious that to deny it would be to discredit all historical testimony.

ii. As little can it be doubted that they were extant from the *commencement* of that century. Not only are they frequently quoted by writers who lived during that period, but we possess *ten* distinct catalogues of the New Testament books, issued during this century, of which six are identical with our present canon (1), three omit only the book of Revelation (2), and one omits this book and the Epistle to the Hebrews (3), though both are mentioned in other parts of the author's writings.

1. Those of the forty-four bishops at the Council of Carthage (A.D. 397), of Augustin (A.D. 394), of Jerome (A.D. 392), of Rufinus (A.D. 390), of Epiphanius (A.D. 370), and of Athanasius (A.D. 315).

2. Those of Gregory of Nazianzum (A.D. 375), of the bishops at the Council of Laodicea (A.D. 364), and of Cyril of Jerusalem (A.D. 340).

3. That of Philaster or Philastrius, Bishop of Brixia or Brescia (A.D. 380).

Lardner, Works, vol. iv., pp. 280-501, and vol. v., pp. 1-123.

iii. Their existence in the *third* century is placed equally beyond doubt, from the careful and explicit testimony of Eusebius, who wrote A.D. 315; from the references to them in the writings of the apologists Arnobius Afer and Lactantius (cir. A.D. 300); from the testimonies contained in fragments preserved from numerous writers in that century, especially Victorinus, Bishop of Pettau in Germany, who refers to nearly every book in the New Testament; from the commentaries upon them and quotations from them of Origen (A.D. 253); from the quotations of Cyprian (A.D. 258); and from references to them in the remains of a number of writers who lived during the first thirty years of the third century.

Lardner, Works, vol. ii., pp. 397-430.

iv. For their existence in the *second* century we have abundant evidence, in the quotations from them and allusions to them in the writings of Tertullian (A.D. 200), Clement of Alexandria, Athenagoras (A.D. 180), Irenæus (A.D. 170), Justin Martyr (A.D. 150), and Papias (A.D. 113), and in the *Harmony of the Gospels* by Tatian (A.D. 170).

v. Collateral with these testimonies of the orthodox fathers are those of the early heretics, Cerinthus, the Ebionites, the Basilidians, Marcion, and others, who, by denouncing the writings of the apostles as containing error, thereby attest the existence and genuineness of these writings; and of the early opponents of Christianity, Celsus, Porphyry, and Julian, who, by the notice they take of these books, show how much in their day their genuineness was matter of public notoriety.

vi. We have thus traced up the existence of these books to the close of the *first* century. To say nothing of the testimony in their favour of the apostolic fathers, Barnabas, Clement of Rome, Hermas, Ignatius, and Polycarp, who flourished during that century, and reached up to the days

Scripture. of the apostles, the supposition of a forgery at that time is clearly absurd. Whilst men were still alive whose fathers were the contemporaries of the evangelists and apostles, how could any one impose upon the community as the production of the latter what was only forged in their name? or whilst the churches at Rome, Colossæ, Corinth, and other places were still existing, who could have persuaded them to receive as Paul's letters to them what they knew Paul had never sent to them? or how can we conceive that an attempt so audacious would have been allowed to pass without a single voice being raised in any quarter to denounce the imposture?

vii. The conclusion thus gained by the consideration of external testimony is forcibly confirmed by the contents of the books themselves. The *language* in which they are written is exactly such as a Jew of the first century would naturally fall into in attempting to write Greek, and such as could hardly have been thought of or imitated by a later writer. The *style* of composition is such as a forger could not possibly have hit upon; it has so much of a prevailing simplicity and earnestness, and at the same time is so suitably diversified in the different books, that it bears every indication of having flowed from the pens of the simple-minded, unambitious, uneducated, and honest men to whom it is ascribed. The *sentiments* are such as we cannot suppose men of sufficiently depraved moral habits to act the part of forgers, to have conceived or inculcated. And above all, the *minute circumstantiality* of the narrative is such as, on the one hand, strikingly indicates the agency of an eye and ear witness in the composition of it, and on the other, affords too many tests of the author's personal familiarity with what he narrates to have been ventured on by a forger. The striking coincidence of one part of the volume with another may also be mentioned as a further evidence of its genuineness.

For these reasons it is concluded that the Scriptures of the Old and New Testament are the genuine productions of those to whom they are ascribed. They are reasons which must satisfy every person familiar with such inquiries, that we possess in favour of the genuineness of these books a far larger and more unquestionable body of proof than we have in favour of the genuineness of any of the ancient classics, and indeed of much even of comparatively modern literature.

See on the whole of this section, Horne's *Introduction*, vol. i., pp. 35-99; Lardner's *Credibility*, Works, vols. i.-v., 8vo i., and ii. 4to; Paley's *Evidences of Christianity*, and *Horæ Paulinæ*; Michaelis's *Introduction* by Marsh, vol. i., pp. 4-54; Marsh's *Lectures on the Authenticity and Credibility of the New Testament*, London, 1840; Cook's *Enquiry into the Books of the New Testament*; Taylor's *Essay on the Transmission of Ancient Books to Modern Times*; Schott's *Isagoge*, pp. 518-542.

SECT. III.—*Integrity of the Sacred Books.*

Closely connected with the question of the genuineness of the Scriptures is the question of their *integrity* or *uncorrupted preservation*. Infidels have often asserted that extensive and important changes have been made upon the original documents, especially upon those of the Old Testament. But,

1. Of this there is no proof. It is a mere unsupported assertion on their part, resting upon nothing but certain *a priori* conclusions to which they profess to have come as to the *probability* of such a thing. To prove it, we should require some competent historical testimony to the fact, or an articulate comparison of the alleged interpolations with the original text.

2. Such interpolations could have been perpetrated only by universal consent on the part of all possessing these documents. Had one man altered his own copy, and published his alterations, the only result would have been

certain discrepancies between the readings of that family Scripture. of manuscripts of which his copy was the parent, and those of other families, unless he could have persuaded the whole nation of the Jews, or the entire body of the Christians, as the case might be, to adopt his innovations,—a supposition plainly impossible.

3. Had extensive alterations taken place, the harmony of Scripture would have been destroyed. A number of separate books are written by different persons, for the purpose of unfolding under different aspects and modifications one harmonious system of truth. The result is a harmonious work. But some person, for purposes of his own, sets about interpolating these books. Is it conceivable that this should have been accomplished with such exquisite skill and adroitness, that the original harmony of the work should have been preserved, and all vestiges of a spurious intermixture concealed?

4. It is morally certain that, previous to the Christian era, the Jews did not alter their sacred books. For this we have sufficient security in the habits and circumstances of the people. The Bible was their national statute-book; on it the whole of their civil economy, and all their political and judicial procedure, rested. They were in the habit of giving the utmost publicity to its contents; kings were required to study it continually, priests were appointed to teach it to the people, and fathers were enjoined to inculcate it upon their children; so that the idea of connivance among the members of any class in the community for the purpose of falsifying it is entirely precluded. Their law contains a solemn prohibitory statute against any, the slightest, alterations of these books, Deut. v. 2, xii. 32. The rival sects which arose among them after their return from Babylon served the same purpose, by acting as mutual checks upon each other. And, finally, in the absence of any censure by our Lord upon the Jews, whose crimes He faithfully exposed, for their treatment of the sacred text, and in His continual references to the Old Testament in the state in which it was then extant, as containing an accurate record of God's will, we have the best assurance that no liberty affecting its perfect integrity had been taken with it previous to His advent.

5. Since the commencement of the Christian era it is equally certain that no intentional corruption of the Old Testament Scriptures can have taken place. The *Jews* have not corrupted them, for they have ever shown too deep a reverence for every word and letter of these books to have done so; they have been too much scattered and disunited to have agreed upon any such attempt; they would not have left so many statements condemnatory of themselves and favourable to Christianity had they set about altering their own Scriptures; and they have since that time been so much under the eye of Christians that any such attempt on their part would immediately have been detected and denounced by the latter. *Christians* have not done it; for, to say nothing of the fact that hardly any Christian has been sufficiently master of the Hebrew language to execute skilfully any such alterations, the attempt on their part to do such a thing would have been immediately discovered and exposed by the Jews.

6. As impossible is it that any corruption has taken place in the Christian Scriptures. It is plain that this could not have occurred during the lives of their authors, nor whilst the autographs of their works were extant. But in some cases before, and in others immediately after, the death of the inspired writers, copies of their writings were multiplied to a great extent, and disseminated over the whole Christian world. It could only therefore have been by the general consent of all Christians that any material alterations could have been made on these writings; for if one sect or party had interpolated their copies, this could not have affected the copies of others, and would have been detected

Scripture. and denounced by them. But the idea of a general consent of Christians in all parts of the world to falsify their own documents, is one too extravagant to be admitted.

7. The agreement of versions and of manuscripts, both of the Old Testament Scriptures and of the New, is a corroborative evidence of their integrity. The number of early versions is considerable, and among them so great a harmony prevails that it is undeniable they must have been made from a common original, and that that original must have been the same as we now possess. The same conclusion is attested by the agreement of the manuscripts. Of these, more than 1100, containing the whole or parts of the Old Testament, and about 1400, containing the whole or parts of the New Testament, have been collated, without any material discrepancy having been elicited (1); a fact which is utterly irreconcilable with the supposition of any designed interpolations having been so much as attempted by any class or party, either of Jews or of Christians (2).

1. Rosemüller observes, respecting the codices of the Old Testament, "I qui hodie exstant codices omnes ita inter se conspirant, ut ex aliquot centenis variis lectionibus vix una deprehendatur quæ sensum mutet. Circa unam duntaxat vel alteram litteram, Vocalem vel Accentum versantur. Quod quidem argumento est, Veteris Testamenti libros, prouti eos nunc legimus, ex unius, quam dicunt, recensione codicibus ad nos transmissos esse, atque omnes codices, antiquiores æque perierunt, ac recentiores quos habemus tanquam a communi fonte fluxisse." (*Præf. ad Edit. Stereotypam Haham Bib. Heb.*, p. iv.) Language no less strong may be justly held regarding the New Testament.

2. See Horne's *Introduction*, vol. i., pp. 100-108; Michaelis's *Introduction*, vol. i.; Walton, *Prolegom.* vii.; Nolan's *Inquiry into the Integrity of the Greek Vulgate*, London, 1815; [Bentley's] *Remarks on Freethinking*, by Philoleutherus Lipsiensis, Nos. xxxi-xxxiii.; Dr J. Pye Smith's *Answer to the Manifesto of the Christian Evidence Society*, 4th ed., and *Rejoinder to Taylor*, 2d ed., London, 1830; Ernesti's *Principles of Biblical Interpretation*, translated by Charles H. Terrot, vol. ii., pp. 1-24, Edinburgh, 1833.

SECT. IV.—Credibility of the Sacred Scriptures.

That these books, in their narrative parts, contain statements of actual facts, is sufficiently established by various considerations.

1. The things narrated are such as their writers were fully competent to attest. For the most part they were eye and ear witnesses of what they recorded; and where this was not the case, they were placed in circumstances the most favourable for gaining information from first sources as to the facts they narrate. They are in fact, with one or two partial exceptions, what very few of the ancient historians are, annalists of their own times.

2. The matters which they record are such as they could not possibly be deceived about. They are such as any man with the use of his senses, and an ordinary portion of discrimination, was as fully competent to judge of as the most profound philosopher. The passage of the Red Sea, for instance, or the re-appearance of our Lord after His death, was a fact respecting which no man in his senses could be deceived. Unless the sacred writers were the wildest enthusiasts (of which, however, no trace is discoverable in any other part of their conduct, but the contrary), they could not have been misled into the belief that they had seen such things, if they had not seen them.

3. The blameless character and disinterested fidelity of these witnesses show that they were not themselves deceivers. The mind of man is subject to certain laws, upon which we may calculate with the same security as upon the laws of matter; and one of these is, that no man of generally irreproachable character will deliberately and pertinaciously propagate a falsehood, save under the influence of very strong temptation. Now the sacred writers were men of respectable character; so that if their narrative be false, it can only have been under the stress of very urgent necessity or sinister inducement that they can be supposed to

have promulgated it. But where was this stress in their case? What evil had they to shun, what prodigious advantage to gain, by falsehood? On the contrary, did not their adherence to their story expose many of them to the severest privations and the cruellest sufferings, even to death itself? Do men, then, ever so fall in love with falsehood as to consecrate their lives to its propagation, and willingly to endure every species of contumely, persecution, and oppression, rather than relinquish it? Would not such a thing be a moral miracle, infinitely more incredible than any of those which the sacred writers narrate, because, unlike theirs, performed not only without the affirmation of divine agency, but in direct opposition to the law of the God of truth?

4. Their narratives were published at a time when the events they record were so recent that it outrages all probability to suppose, either that they would have had the audacity to publish what was false, or that their falsehoods would have been allowed to descend to posterity uncontradicted. Who can for a moment imagine that, had the Israelites not crossed the Red Sea in the manner described by Moses, he could have persuaded them to believe that they had? or that the facts of our Lord's history could have been palmed upon the world when there were so many still alive both interested in and competent for their refutation, had they not really occurred?

5. These histories account satisfactorily for numerous undeniable facts that are otherwise unaccountable, such as the existence and present state of the Jews, the existence and propagation of Christianity, and the prevalence of certain rites and ceremonies among Jews and Christians, such as circumcision in its religious aspect, the weekly Sabbath, the Lord's Supper, &c. They further tally with the testimony of profane history, in as far as the field is common to both. They "interweave themselves," as Dr Channing has well observed, "with real history so naturally and intimately as to furnish no clue for detection, as to exclude the appearance of incongruity and discordance, and as to give an adequate explanation, and the only explanation, of acknowledged events of the most important revolutions of society." That such narratives should be fictitious, the same writer justly concludes, "is a supposition from which an intelligent man at once revolts, and which, if admitted, would shake a principal foundation of history." (*Discourse on the Evidences of Revealed Religion*, p. 34, 4th [English] edition, Liverpool, 1831.)

6. The credibility of the sacred historians is strikingly confirmed by the traditions and histories of all the ancient nations, by many facts of natural history, and by numerous monuments of human art which are still existing, such as coins, medals, and inscriptions.

See Faber's *Horæ Mosæicæ*, vol. i.; Bryant's *Ancient Mythology*, 3 vols. 4to, 1774; Edwards on the *Truth and Authority of Scripture*, vol. i.; Gray's *Connection of Sacred and Profane Literature*; Lardner's *Credibility*, and *Jewish and Heathen Testimonies*, &c. Works, vols. i.-viii.; Redford's *Lectures on the Divine Authority of the Bible, as confirmed by Science, History, and Human Consciousness*, 1837; Horne's *Introduction*, vol. i., 116-20; Alexander's *Christ and Christianity*, part i.

SECT. V.—Canon of the Sacred Scriptures.

The Greek word *καὶν* signifies originally a *straight line* or *rod*; hence tropically a *rule*, and hence a *list* or *catalogue*, as that which contains the rule or order of the things contained in it.

In this last sense it is applied to the Scriptures, but with a different reference, according as it is used in inquiries of a dogmatical or in inquiries of a historico-critical nature. In the former, it means the list of books deemed *inspired*; in the latter, the list of books recognised as *genuine* by Jews and Christians. In either case, such books are opposed to those that are *apocryphal* (*ἀποκρυφα*, "ea scripta

Scripture.

Scripture. quibus publice ecclesia non utebatur, sed *privatim* habebat legebaturque qui vellet." (*Ludovicus Vives ad Augustin. de Civ. Dei*, l. xv., c. 23.)

In regard to the sacred writings, both these lists are identical, for all the books which are found in the former are found also in the latter, no book having been inserted simply on the ground of its Jewish authorship, but only such as were the production of a prophet or inspired man.

See the striking testimony of Josephus, *Cont. Apion.* i. 8, confirmed by that of Philo, by whom no writing is referred to as sacred unless it be the production of a *πρᾶξις*, by which term he intends one whose "organs are used by God for the showing of what He wills." (*De Monarch.* opp. ii. 222, ad. Mangey.)

It is the opinion of some that Nehemiah, who is said to have collected a *βιβλιοθηκη* of the sacred books (2d Macc. ii. 13), and Malachi, the last of the prophets, closed the canon by adding to it their own writings; though others affirm that the list was not finally made up until about the time of the Syrian invasion under Antiochus Epiphanes, in the third century B.C. By much the most probable, because best-supported hypothesis, however, is that which ascribes the final and authoritative making up of the Old Testament canon to Ezra and the men of the Great Synagogue. This is formally affirmed in one of the oldest books of the Talmud, the *Pirke Aboth*, or Sayings of the Fathers, and it is repeated in other Jewish writings; it is, besides, in full accordance with all we know of Ezra's personal history and his position among his people, and there is nothing of any weight that can be urged against it. Before the time of Ezra there was a succession of prophets by whom the integrity and purity of the sacred canon was guarded; and Ezra and his associates simply declared finally what always had been, and were to be thenceforward, held as the sacred books. Certain it is that by the third century B.C. all the books now extant had been composed and arranged in order,—as they not only were then translated into Greek, but were spoken of by Jesus Siracides, who lived about two hundred years B.C., as divided into three classes, and as of considerable antiquity. Even if we admit that the closing of the canon took place as late as the time of Antiochus Epiphanes, it must have consisted only of such books as were notoriously reputed among the Jews to be sacred, as having come down to them from the prophets; for it would have been impossible at that time to have induced the nation to accept as of Divine authorship, books which they knew must have been produced since the succession of the prophets and inspired men had ceased.

The classes into which the books of the Old Testament are spoken of by the son of Sirach as divided, are three,—the law, the prophets, and the other writings. This division is still retained, only the last class are denominated Chetubim or Hagiographa. To the first division belong the five books of Moses; to the second the historical books, with the exception of Ruth, Ezra, Nehemiah, and Chronicles, and the prophetic books, with the exception of Daniel; to the third the poetical books, Daniel, and the excepted historical books. This arrangement, however, was by no means uniformly preserved. In the LXX. Daniel is placed next to Ezekiel; Josephus and the New Testament writers seem to have regarded the third division as comprising only the poetical books; and there is considerable discrepancy among the Jewish rabbis in their statements as to the arrangement of the sacred books. All this seems to indicate that the Talmudical arrangement now followed was not the original arrangement, but was one which, probably for liturgical purposes, the Jews adopted at a later period.

See Vitringa, *De Synagog. Jud.*, lib. iii., 2, 10.

At what time the canon of the New Testament was made up we have not the means of accurately determining. We are sure, however, that from a very early age these writings were separately referred to as divine and authorita-

tive, and as on these grounds quite *sui generis*; and it is certain that they were at an early period collected, and were referred to in their collected character as the received documents of the Christian community. Tertullian does so repeatedly in his writings, denominating them sometimes "the New Testament," and sometimes "the Divine Instrument," in the singular number; and Clement of Alexandria speaks of "the Scriptures of the Lord" under the title of "The Gospel and the Apostles." The collection was doubtless made gradually; and from what we learn from Eusebius respecting a distinction between books *ὁμολογούμενα* and books *ἀντιλεγόμενα* (*Hist. Ecclesiast.*, lib. iii., c. 25, ed. Heinichen, vol. i., p. 244), it would appear that the claims of every book were carefully weighed before its canonicity was admitted.

See Cosin's *Scholastical History of the Canon of the Holy Scripture*, London, 1672; Jones's *New and Full Method of Settling the Canonical Authority of the New Testament*, Oxford, 1798; Alexander's *Canon of the Old and New Testament Ascertained*, London, 1828; Ch. F. Schmidt's *Historia Antiqua et Vindicatio Canonis Veteris et Novi Testamenti*, Lipsiæ, 1775; Haenlein's *Einleitung in die Schriften d. N. T.* bde. i. s. 341, Erlangen, 1801; Henderson's *Lectures on Inspiration*, lect. ix; Stuart, *Critical History and Defence of the Old Testament Canon*, Lond. 1849; Westcott's *History of the New Testament Canon*.

The apocryphal books of Scripture may be divided into two classes, the one containing those that are simply dogmatically, the other those that are both dogmatically and historico-critically apocryphal. To the former belong the books of Maccabees, Wisdom, Ecclesiasticus, and perhaps those of Tobit and of Judith, which are genuine, though not inspired; to the latter all the rest of the apocryphal books, both of the Old Testament and the New, none of which are inspired, or can be shown to be genuine.

T.*; Bretschneider, *De Libri Sapientiae*, &c., 1804; Josephus, *Cont. Apionem*, i. 8; Hieronymi, *Præfat. in libb. Salomonis, et in Judith et Tobiam*.

SECT. VI.—Languages of the Scriptures.

The greater part of the Old Testament Scriptures is composed in pure Hebrew, the most ancient language of which we have any specimen extant. This language belongs to a class of tongues formerly called, by way of eminence, the *Oriental*, but now more generally discriminated by the term *Semitic* or *Shemitic*, from Shem, the great progenitor of the races by which they are spoken (1). This class embraces three leading tongues, corresponding in general character and relation to the geographical situations of the respective nations by which they are used; the *Aramaic*, abounding in combinations of consonants, and consequently marked by considerable harshness of pronunciation, employed by the nations of the northern and more mountainous districts of Syria, Mesopotamia, and Babylonia; the *Arabic*, remarkable for richness, mellifluousness, and the preponderance of vowels, spoken by the inhabitants of the warm and open plains of Arabia and Ethiopia; and the *Hebrew*, the language of the middle district, possessing an intermediate character between the other two, richer than the Aramaic, poorer and harsher than the Arabic (2). Of the Aramaic in its original form we have no remains. The biblical Chaldaic is a mixture of it, as used in Babylon, with the Hebrew; the Syriac is a more recent dialect, formed by the Christians of Edessa and Nisibis (3). The opinion, that Hebrew was the original language of the world, and the mother of all the other Semitic tongues, is now generally relinquished by scholars, who content themselves with the more moderate hypothesis, that it is the oldest daughter of the primeval tongue, and that which re-

Scripture. tains the most striking resemblances to the mother speech of the antediluvian period (4). The term *Hebrew* some derive from עֵבֶר, *Eber*, *over* or *across*, as if = *advena*, *foreigner*, *immigrant*; but others, with far more probability, from עֵבֶר, *Eber* or *Heber*, the ancestor of Abraham. In the earliest books of the Bible, those of Moses, this language appears in its greatest purity; nor did it sustain any decided deterioration till after the Babylonian captivity. The attempts of some Hebraists to divide its history into a golden, a silver, a brazen, and an iron age, are by the most accurate scholars rejected, as much more fanciful than sound (5). The Hebrew of the Scriptures is the pure classical Jerusalem Hebrew, the language of the Temple and of the court. That there were dialects more or less corrupt in the provinces is attested by the sacred writers themselves. Thus they tell us that the Ephraimites could not distinguish between the ו and the ב in pronunciation (Judges xii. 6); Nehemiah was indignant that part of the people should speak "in the speech (dialect) of Ashdod, of Ammon, and of Moab" (Nehem. xiii. 23-25); and the dialect of Galilee is mentioned in the New Testament (Matt. xxvi. 73) (6).

1 The first to use this term seems to have been Nicolas Fuller in his *Miscellanea Sacra*. He was followed by Eichhorn, and ultimately by nearly all the orientalists of Germany. Havernick contends for retaining the term *Oriental*. *Introduction to Old Testament*, p. 82.

2 Ewald's *Hebrew Grammar*, translated by Nicolson, p. 1; Gesenius, *Grammatik*, § 1.

3 See Havernick, *Gen. Introd.*, p. 99.

4 Morinus, *De Lingua Primæva*; Jahn, *Einleitung*, i. th. s. 244.

5 "As the language appears to us at present in the Scriptures of the Old Testament, there are only two distinct periods characteristically discriminated,—the one comprehending the books written before, and the other those written during and subsequent to the exile." Gesenius, *Geschichte der Hebr. Sprache und Schrift*, s. 21.

6 Compare Horne's *Introd.*, v. ii., p. 2-14, and the works referred to by him.

The portions of the Old Testament not in pure Hebrew are Ezra iv. 8, vi. 18, and vii. 12-26; Jer. x. 11; and Daniel ii. 4, vii. 28. These are in Chaldaic or eastern Aramaic, and have reference chiefly to the history of the Captivity, and the events following its close.

On the Biblical Chaldaic, see Walton's *Prolegomena*, chap. xii. §§ 2, 3; L. Hirzel, *De Chaldaismi Bibliæ Origine et Auctoritate Comment. Crit.*, Lips. 1830; F. Dietrich, *De Sermonis Chaldaici Proprietate*, Lips. 1839; Winer, *Grammatik des Biblisch. und Targumischen Chaldaismus*, Leipzig, 1842, 2d edit.; *Chald. Lesebuch*, 1825.

The language of the New Testament is the κοινή διαλεκτος of the classical Greek, with many Aramaic words and idioms interspersed, and a few Latinisms.

Horne's *Introd.*, vol. ii., pp. 13-30; Schott, *Isagoge Hist. Crit.*, pp. 495-617; Stuart's *Grammar of the New Testament Language*; Winer's *Grammatik des N. Testamentlichen Sprachidioms*, translated by E. Masson, 2 vols., Edin. 1858; Michaelis, *Introd.*, vol. i., p. 97 (English translation), &c.; Davidson's *Biblical Criticism*.

SECT. VII.—History of the Original Text of the Old Testament Scriptures.

The history of the Hebrew text properly begins after the completion of the canon; antecedent to that, we have no materials for arriving at any conclusions. Starting from this point, the history of the Hebrew text may be divided into three great epochs. The *first* of these reaches from the completion of the canon to the times of Origen, Jerome, and the Talmud, B.C. 300—A.D. 500. During this period we observe,—(1.) Attention paid to the caligraphy of the text, and the adoption of the square character from the Aramaic or Babylonian usage, in place of the old Hebrew or Samaritan. (2.) The attempt to ascertain the correct reading of the text, and the collection of various readings. Of these, it is

Scripture. natural that a considerable number should have accumulated; for, without resorting to the supposition of any blameable carelessness on the part of the transcribers, still less of any intention to alter the text, there were sufficient causes at work to occasion numerous varieties between one manuscript and another; such as mistakes of eyesight or of hearing, leading to the substitution of one letter for another resembling it, the transposition of letters and even of words, the omission of letters and even clauses, the substitution of like-sounding words for each other, &c.; mistakes of memory, when the transcriber trusted to recollection, leading to substitutions and omissions, the confusion of synonyms, and the exchanging of familiar parallel passages; and mistakes of judgment, where two words are sometimes read as one, abbreviations are wrongly construed, marginal glosses are introduced into the text, and such-like. When the LXX. is compared with the extant Hebrew text, it is evident that its authors must have used manuscripts in many respects differing from those which have come down to us from the Palestinian Jews, and by which the extant text has been determined. With the LXX. agrees the Samaritan Pentateuch, which contains also some variations peculiar to itself, but of no critical value, as they are plainly occasional glosses or unskilful corrections. Nor can any great value be attached to the various readings of the LXX., the most of which are arbitrary and uncritical, though there may be some which are worthy of being considered. Among the Jews of Palestine, the most reverential care was exercised upon the sacred text to preserve its purity; and it would appear from the Talmudists that at an early period the text was fixed very much as we now have it, the variations being adduced merely as *keri* (read) upon *chetubh* (written); i.e., what, for critical, exegetical, or euphonic reasons, was in the reading to be substituted for what was written. (3.) Attention came to be paid to the correct pronunciation of the words and the reading of the text. As Hebrew had ceased to be a spoken language, and as the manuscripts of Scripture were without vowels, it became necessary to call in the aid of tradition to fix the form and meaning of the words; and accordingly in this period commenced those attempts which ultimately culminated in the elaborate system of the Masoretes. Besides this, care was taken to determine one word from another, and to mark the ending of clauses and sentences. (4.) Of the Hebrew text as it existed among the Palestinian Jews some judgment may be formed from the extant fragments of the Hexapla of Origen, and from the Targums. It differs but slightly from the existing Masoretic text. Of great value also is the testimony of Jerome, by means of his translation and his commentaries, to the substantial identity of the text in his day with that now extant.

In the *Talmud, Hierosol. Tract. Thaani*, fol. lxviii., it is said of certain various readings that "they have come down from the times when the Temple was yet standing." Capelli *Critica Sacra*, tom. i., p. 444-458; Walton's *Prolegomena*, viii., §§ 20-28; Kennicott, *Dissert. Generalis*, p. 275; Horne's *Introduction*, vol. ii., p. 35, 36; Buxtorf's *Tiberias*; Havernick's *Introd.*, §§ 41-61, Tr.; De Wette, *Evnl.*, §§ 85-89, p. 126, ff.; Porter's *Textual Criticism*, p. 43, ff.

The *second* epoch reaches from the times of Jerome and the Talmud to that of Ben Asher and Ben Naphthali; that is, from the sixth to the eleventh century. About the commencement of this period the Masorah, or collection of traditional observations, orthographical, critical, grammatical, and exegetical, which had been accumulating for upwards of three centuries among the Jewish rabbins, began to be made by a college of learned Jews at Tiberias in Palestine. These were originally written on the margin of manuscripts, but as this led to confusion and error, they were ultimately collected in separate books. Of these annotations, some are the result of the comparing of manuscripts, and to this the various lections belong; others are the result of private

Scripture. judgment, and are chiefly of a grammatical or exegetical nature. The Masorah is distinguished into *great* and *little*, according as the remarks are given in full or in an abridged form. The former, from being put by itself at the end, was called *final*, the latter *marginal*. To this mass of scholia additions were continually made, as well as corrections proposed on it, by the *Lords of the Masorah* (בעלי המסורה), as they were called, until the time of Jacob Ben Ha-yim, by whom the whole was completed, and printed along with the Hebrew text, in the year 1526. The commencement of the eleventh century is memorable in the history of the Hebrew text, from the circumstance of two recensions having been issued by the heads, as is supposed, of two celebrated Jewish academies: by Aaron Ben Asher, principal of the academy of Tiberias, and Jacob Ben Naphthali, principal of the academy of Babylon. These, taken in connection with a list appended by Ben Ha-yim, from some unknown source, to the second Bomberg Bible, have given rise to the various readings denominated the occidental and the oriental respectively. By them also the last hand was put to the pointing of the Hebrew text.

Capelli *Crit Sacra*, t. i., pp. 439-443; Simon, *Histoire Critique*, ch. i., pp. 24-26; Kennicott, *Dissertationes*, ii., p. 279; Buxtorf, *Tiberias*, 1610; Marsh's *Lectures*, lect. viii., ed. 1828; Walton, *Prolegom.*, viii. 12; Horne, vol. ii., pp. 39, 40. Havernick and De Wette as above.

The *third* epoch reaches from the beginning of the eleventh century to the middle of the eighteenth. About the year 1040 many learned Jews, banished from the East, took refuge in Europe, and brought with them their Scriptures and their critical learning. Maimonides, Jarchi, Ebenezra, Kimchi, and others, rendered additional service as to the interpretation, so also to the criticism, of the sacred text. In the thirteenth century, R. Meir Hallevi, called commonly Todrosus, and in the sixteenth, Menachem and Sal. Norzi, collected various readings. In 1477 the first scriptural book in Hebrew, in 1488 the entire Hebrew Bible, for the first time, was printed; the latter at Soncino, the former at some place unknown. That of 1488 is the first principal edition of the Hebrew Bible; the second is the Complutensian polyglott, 1514-17; and the third, which is of great importance, is the so-called *Rabbinical Bible*, printed at Venice in 1526, and edited by Ben Ha-yim. Among Christian editors, Sebastian Munster was the first who issued an edition of the Hebrew Bible, with various readings, Basil, 1535. The editions of Joseph Athias, Amsterdam, 1661, Manasseh Ben Israel, Amsterdam, 1630, are worthy of notice as critical editions. In 1690 Jablonski published his edition, in which the text follows that of Athias, with some aid from manuscripts. John Henry Michaelis published his edition at Halle in 1720, for which he collated five manuscripts and nineteen editions. In 1753, at Paris, appeared the edition of Charles Francis Houbigant, for which twelve manuscripts were collated, but the value of which is greatly impaired by the editor's propensity to conjectural emendation, and by his attaching such undue importance to the readings of the Septuagint. The splendid work of Kennicott (Oxford, t. i. 1776, ii. 1780) presents the largest mass of various readings yet collected; but the want of scientific discrimination as to their relative value has impaired the usefulness of the collection. The same may be said of the various readings collected by De Rossi, Parma, 1784-1788.

Marsh's *Lectures*, lect. ix.; Horne, ii., pp. 27-46; Augusti, *Einführung*, §§ 85-92; De Rossi, *De Heb. Typog. origine et primitiis*, Parma, 1776; Havernick, §§ 66, 67.

SECT. VIII.—History of the Original Text of the New Testament Scriptures.

Of the autographs of the New Testament writers no notices have come down to us; what have been supposed

to be allusions to them by some of the fathers are only by mistake so interpreted; while the stories of some of the later writers, such as Theodorus Lector, Philostorgius, Nicephorus, and the Chronicon Paschale, are to be referred to the head of fables. Written on papyrus (3 John 13), they were not calculated to endure long, and as copies of them had been made, no special effort was probably made to preserve them. Of these copies, there is reason to believe the number soon came to be very considerable. But in making them, it was hardly possible to avoid mistakes more or less serious. The text ran on in an unbroken current, without separation of words, without interpunction, and without any of those diacritical marks which appear in printed Greek books: it was in the ancient character where many of the letters resemble each other closely, and the transcription was executed by scribes, who were subject to all the errors arising from imperfect seeing, imperfect hearing, or misunderstanding. Sometimes, also, alterations were intentionally introduced for dogmatical or grammatical reasons. Hence, as early as the second century, it is clear that varieties of reading existed, and these would naturally accumulate during the long period that intervened before the discovery of printing. That attempts were made at an early period to arrive at a correct text is certain, but it is not easy to determine of what kind or value these were. We have the testimony of Jerome, confirmed by that of the decree of Gelasius, that Lucian, a presbyter of Antioch, and Hesychius, an Egyptian bishop, undertook some sort of recension of the New Testament, but we are left in the dark both as to what they really effected, and as to what influence, if any, their labours had on the accredited documents of the Christians. It is certain also that the labours of Origen were directed with beneficial effect upon this object; and though Jerome sometimes allowed merely arbitrary preferences to overrule his critical judgment, there can be no doubt of his eminence as a textual critic, and of the value of his services towards a just settling of the text of the New Testament.

Modern critics have endeavoured to facilitate and settle critical inquiries by arranging the documents containing the original text of the New Testament into *classes* or *recensions*, as they have been called. Of these documents, some more, and others less, closely resemble each other as respects the nature and selection of their readings, and not unfrequently traces of a common origin in the older codices and versions are apparent. This has led to the idea of arranging these into *classes*, or *families*, or *recensions*, an idea first started by Bengel and Semler (1), and which has been carried out by several more recent inquirers. Bengel concluded that there are two families of manuscripts, the African and Asiatic, of the former of which the Alexandrian manuscript is the sole representative (with which agree the Ethiopic, the Coptic, and the ancient Latin versions), whereas the latter is very numerous. After Bengel came Griesbach (2), who contended for a threefold recension, the Western, the Alexandrian or Eastern, and the Constantinopolitan or Byzantine. Of these, the two former are the oldest, and are by him attributed to the same age. They differ, in that the Western text is more replete with Hebraisms, with explanatory additions, and with occasional substitutions of a perspicuous formula for one more difficult; whilst the Eastern prefers those readings that are accommodated to the classic Greek, corrects phrases that are less pure, and is less deformed by errors of the transcriber, though particles and synonyms are occasionally omitted through haste. The Constantinopolitan has arisen from the mingling of the readings of the other two. It properly consists of *two* recensions: a senior (fourth century), even more fond of pure Greek forms, and richer in glosses, than the Alexandrian itself; and a junior (fifth or sixth century), which appears to have been formed after a new collation of

Scripture. the senior with the Eastern and Alexandrian recensions, by the labours of some learned men of the Syrian Church. Griesbach defends his system with great learning and ingenuity; but it is open, as Schott observes, to the following objections:—1st, His positions respecting the origin assigned to both recensions are destitute of a solid basis; 2dly, Many reasons concur to prevent our admitting that any state of the text of the New Testament peculiar to the Western Church, such as could, from its singular character, be entitled to the name of a recension, existed (3); 3dly, The features of the text followed by the very ancient Peschito version cannot well be accounted for on the principles of Griesbach; and, in fine, all who seek accurately to arrange codices, versions, and extracts found in the fathers, according to different recensions, labour under this difficulty, that none of those documents of the New Testament which are of great age exhibits any such pure and perfect recension (4).

1 Bengel, *Apparatus Criticus ad Novum Test.*, p. 425, Tübingæ, 1763; Ejusdem, *Introductio in Crisin N. T.*, § 26, &c., p. 385, Tübingæ, 1734; Semler, *Vorbereitungen zur Hermeneutik*, Halle, 1760–1769. The term *recension*, though now generally used, is a misnomer. The manuscripts may be reduced to different classes, but there is no evidence that any of these is the result of a recension.

2. Griesbach, *Opuscula Academica*, ed Gabler, vol. i.

3. From the writings of the fathers of the second century, we learn that those various readings which are said to be peculiar to the western and to the eastern texts respectively, do not, as respects their origin, belong to different recensions. (See Eichhorn, *Einl.*, bd. iv., pp. 265 and 269, &c.) Nor is it probable that the doctors of the Western Church, who were but little skilled in Greek, should have thought of preparing a recension of the New Testament.

4. Schott, *Isagoge*, pp. 562–565.

A different theory of recensions has been adopted by Hug. He thinks that the text which we find in those early codices which Griesbach referred to the Western recension, in the oldest Latin versions, in the Sahidico-Coptic version, in the quotations of the fathers till the time of Origen, and in Origen himself, was the *κοινή έκδοσις*, or common edition, conformed to no recension in particular, and containing various readings of different sorts and of different origins mingled together, especially such as serve to explain the text. At the same time those codices which were written in Syria and other parts of the East (the inhabitants of which understood better than most others the Hebrew-Greek dialect of the New Testament) preserved the primitive text more correctly; and hence it happened that the oldest Syriac version, though upon the whole belonging to this common edition, not unfrequently dissents from the readings of the other documents of the same edition. About the middle of the third century, Hesychius, an Egyptian bishop, first set about correcting the errors of the recension of the common edition used in Egypt, purging out all interpolations and glosses, restoring words that had been omitted, but aiming too much at producing a text that should be remarkable for its Greek purity and elegance. Almost at the same time Lucian, a presbyter of Antioch in Syria, revised the common edition as it appeared in the Peschito version, following chiefly the authority of this version, but at the same time comparing other codices found in Syria, and produced a text differing from that of Hesychius in this, that it showed less desire to amend the Greek of the New Testament. Besides these, a third recension was undertaken by Origen in Palestine, based upon the common edition used by the Christians there, which conformed in some respects to that of Hesychius, in others to that of Lucian, whilst frequently it differed from both, and which subsequently became the one commonly used in Palestine and the adjoining districts. Of these recensions none is preserved in any of those documents which we now possess, as the transcribers frequently compared their recension with the common edition and with other recensions. Hug's theory rests so far on an historical basis that it ap-

pears certain that, as already observed, Hesychius and Scripture. Lucian did undertake some such labour as he ascribes to them; but that codices of their recensions were either very numerous or very highly esteemed, cannot be shown. The labour attributed to Origen is more than doubtful.

Hug, *Einleitung*, bd. i., § 126 (Eng trans. vol. i., p. 134, &c.); Schott, *Isagoge*, p. 566; Horne, ii., p. 56.

Matthæi thinks that no recensions of the text of the New Testament were anciently made, and he prefers dividing the documents from which the text is to be determined into, 1st, *Codices textus perpetui*, in which there are neither scholia nor commentaries, and which excel all the others in the purity of the text they exhibit; 2d, *Lectiōnaria*, which contain the lessons read in churches, and exhibit a text less free from scholiary interpolation than the preceding; 3d, *Codices mixti*, which contain scholia and interpretations partly on the margin, but chiefly interpolated. Matthæi thought the Moscow manuscripts, which he had himself diligently collated, the best; and this perhaps led him to a very unjust estimate of the worth and authority of many other documents of the text of the New Testament.

Schott, *Isagoge*, p. 570; Horne, ii., p. 50.

Scholz, a recent editor of the Greek New Testament, adopts neither the opinion of Griesbach nor that of Hug. He concludes that there are two classes of critical witnesses for the text of the New Testament, the Alexandrian and the Constantinopolitan or Byzantine; to the former of which belong all the codices executed in Egypt and Western Europe, the most of the Coptic and Latin versions, the Ethiopic version, and the quotations by ecclesiastical writers of these districts; and to the latter all the codices written in Asia Minor, Syria, Palestine, and Eastern Europe, the Philoxenian Syriac version, the Gothic, the Georgian, the Slavonian, the quotations by the fathers living in these regions, and all printed editions. The former he infelicitously calls *occidental*, the latter *oriental*. To manuscripts of the latter class he attributes superior value, because of their greater harmony, and of their having been more faithfully copied from original documents than those of the former, which often exhibit a text altered at the will of grammarians; and especially because they present the text used in the public services of the church. But this last position is far from being certain; and, besides, a twofold difficulty presses upon the theory of Scholz; for, first, the Western text of the New Testament has a character considerably different from that of the Alexandrian; and, secondly, the text divulged at Constantinople by order of Constantine and Constans was, as Scholz himself admits, collated with the Alexandrian text; so that the readings of both recensions were intermixed. It is, moreover, rather assumed than proved that that form of the text which, during the first three centuries, prevailed in Asia Minor and Greece, was the same which was afterwards divulged principally in the Constantinopolitan codices; nor is it sufficiently clear that Alexandria was the primary seat of the arbitrary corruption of the New Testament text.

Scholz, *Proleg. ad editionem N. T.*, vol. i.; Schott, *Isagoge*, p. 570; Horne, ii., pp. 58–66.

The theory of Eichhorn approximates that of Hug. He grants that from a very early age different readings, derived from various sources, existed, and were vastly augmented in the third century by various efforts of an exegetical nature, so that as early as the second century there were two species of texts, the Asiatic and the African, but neither of them was determined by any very certain critical laws. He denies that Origen was the author of a peculiar recension, but admits the services of Hesychius and Lucian in this respect, although he questions the possibility of ascertaining accurately the primitive character of either recension from ancient documents. There thus arose a three-

Scripture. fold text of the New Testament, the African (Alexandrian), the Asiatic (Constantinopolitan), and a mixed, which had its source from this, that many, notwithstanding the authority acquired by the recensions of Hesychius and Lucian in the churches of Africa and Asia, preferred following the authority of older codices. No change of a critical kind took place upon the text thus formed until editions of the New Testament began to be printed. No opinion so fully accords with what may be regarded as best ascertained as this of Eichhorn, though it is still doubtful whether the efforts of Hesychius and Lucian exerted a very wide or lasting influence upon the form of the text of the New Testament.

Eichhorn, *Einleitung in das N. T.*, bd. iv, § 183, &c.; Schott, *Isagoge*, p. 572, from which work the above account has been principally taken; Horne, ii, p. 57.

Of late, a disposition has showed itself in some quarters to rest the text solely on the authority of the oldest or uncial codices. This principle, suggested first by the illustrious Bentley, has been embraced and rigidly applied by Lachmann, a recent editor of the New Testament, who has sought to produce, as near as may be, not the best text of the New Testament, but a contribution towards the ascertaining of that, by the reproduction of the text as it was recognised by the church in the fourth century. Lachmann's attempt is generally considered to be a failure, from the extremely narrow basis on which he forced himself to build; but his principle of confining himself to diplomatic evidence alone, to the exclusion of all considerations of the nature of internal evidence, and to diplomatic evidence drawn from the oldest sources, has been eagerly adopted by several critics. Its principal defender and follower in this country is Mr Tregelles, who is at present (1859) engaged in carrying through the press an edition of the New Testament, of which the text is to be based on ancient authorities alone, with various readings from the ancient manuscripts, the ancient versions, and the early fathers. This principle would be unimpeachable, if it could be shown that a reading found in an ancient authority is therefore older than a reading found in a later codex; but so long as it is possible that a later codex may have been transcribed from one more ancient than the oldest of the extant codices, this cannot be done; and, consequently, to restrict authority to the oldest documents is to narrow arbitrarily the field within which evidence may be legitimately sought for the formation of the text. Hence Tischendorf, the most recent, and on the whole the ablest editor of the Greek New Testament, has in his editions allowed himself a much wider range. Whilst he bases his text on the authority of the older witnesses, he includes among these codices as late as the ninth century, and maintains that the lections furnished by codices of the eighth and ninth centuries are often older than those furnished by codices of the fourth, fifth, and sixth, as tested by concurrence with the testimony of the old versions and the early fathers. Hence he concludes that when "it cannot be determined by learned reason and judgment what the authors themselves wrote, that reading which we know to be best supported by ancient witnesses is faithfully and alone to be followed; but wherever causes of a grave nature, and remote from arbitrariness, conspire to recommend and confirm one rather than another, that is to be preferred; not that which is most attested, but that which is attested and probable."¹

With the exception of some detached portions, the first printed editions of the New Testament were those of the Complutensian Polyglott, 1514, and of Erasmus, Basle, 1516. The next possessing any critical value were those

of Robert Stephen,² viz., that of 1546, 12mo, commonly called, from the first words of the preface, the "*Ō Mirificam*" edition, that of 1549, 12mo, and that of 1550, folio. Beza was the first to issue an edition of the New Testament with a copious critical apparatus; and his edition many of the minor editions for several years followed. The beautiful editions of the Elzevirs, which conform partly to the text of Stephen, partly to that of Beza, became so famous that they formed what has been called the *textus receptus*. In 1707 the edition of Mill was published at Oxford, in which not only is there a larger collection of various readings furnished, but also a more scientific discrimination of these aimed at, than in any preceding edition. His example was followed by Bengel in Germany and Wetstein in Holland, both of whom have rendered important service to the text of the New Testament. All these, however, have been outstripped in diligence, learning, and acuteness by Griesbach, who issued his first edition, which embraced only the historical books of the New Testament, at Halle, 1774-75. In the meantime, the researches of Matthæi, Alter, Bûch, and others, had greatly enlarged the mass of materials for a critical revision of the New Testament, and of these Griesbach eagerly and ably availed himself in preparing a critical edition of the whole New Testament. This he published in two volumes large octavo, the former in 1799, and the latter in 1806, at Halle. A new and carefully revised edition was undertaken after Griesbach's death by Dr David Schulz, of which the first volume appeared in 1827. It is to be regretted that this very valuable edition went no further. Passing over those who have merely reprinted the text of Griesbach, or worked solely on his materials, the following editions deserve to be noticed:—Scholz, *Nov. Test. recensuit, lect. familias subj.*, &c., 2 vols. 4to, Lips. 1830-36; Lachmann, *Nov. Test. Græce et Latine*, &c., 2 vols., Berol. 1832-50; Tischendorf, *Nov. Test. ad antiquos testes denuo recensuit*, &c., seventh edition, Lips. 1859. Two useful editions of the New Testament have been recently issued in this country: the one by Dr S. T. Bloomfield, formed upon a careful collation of all previous critical recensions, of which the ninth edition, 2 vols. 8vo, appeared at London in 1855; the other, not yet finished, by H. Alford, B.D.

Marsh's *Lectures*, lects. ii.-vii.; Schott, *Isagoge*, pp. 631-642; Horne's *Introduction*, vol. ii., part ii., pp. 11-35; Michaelis, *Introduction*, by Marsh, vol. ii., pp. 159 and 429; Ernesti's *Principles of Interpretation*, vol. ii., p. 47; Tregelles *On the Printed Text of the Greek N. T.*; Davidson's *Biblical Criticism*, p. 534, ff.

SECT. IX.—*Manuscripts of the Sacred Text.*

Hebrew manuscripts are of two classes, the *rolled* and the *square*: the former prepared for the use of the synagogues, and written only on parchment; the latter for private use, and written sometimes on parchment and sometimes on paper. In all the ancient manuscripts the words are written continuously without any division, and in the square Chaldaic character. They are divided by De Rossi into three classes,—viz., 1. *The more ancient*, or those written before the twelfth century; 2. *The ancient*, or those of the thirteenth and fourteenth centuries; 3. *The more recent*, or those written at the end of the fourteenth or beginning of the fifteenth century. The number of manuscripts collated by Dr Kennicott was about 630, and by De Rossi 479.

Kennicott, *Dissert. Generalis*; Tychsen, *Tentamen de variis Codd. Heb. MSS.*, 1772; Horne, vol. ii., pp. 76-80, pp. 86-103, ed. 1856.

¹ Prologomena to 7th edition of his New Testament, p. xxxii., Lips. 1859.

² This is commonly written *Stephens*, but the correctness of this may be questioned. The French *Etienne*, which was the vernacular name of this illustrious family, is equivalent to our *Stephen*, and the proper Latin form of Stephens would be *Stephanus* and not *Stephanus*.

Scripture.

Manuscripts of the Greek New Testament were written first on Egyptian papyrus, and then, as this was found too subject to decay, on skins. Subsequent to the twelfth century, silk paper was used for this purpose, until the thirteenth century, when cotton or linen paper came into use (1). For the first eight centuries the manuscripts were written in uncial letters, large, erect, and not united either by strokes or hooks. From the beginning of the ninth century the cursive letters were employed, which are smaller, more inclined, and united with strokes; they have, moreover, the *iota* subscribed (2). At first all the words were written without any diacritical marks or separation; but as this was found inconvenient and productive of mistakes, especially in the public reading of the New Testament, a plan was introduced to remedy it by Euthalius, then a deacon at Alexandria, in the fifth century, which consisted in so arranging those words that make one sense as that they should compose one stich (*στιχον*) or line (3). To save room, subsequent transcribers, instead of arranging these in distinct lines, marked the conclusion of each by a colon or point; and thus by degrees arose a complete grammatical punctuation, which is presented in manuscripts from the tenth century downwards, though it was not till the sixteenth century that it was subjected to fixed rules in the editions then printed. From a very early period the custom prevailed of dividing the text into sections (*κεφαλαια*), but until the time of Euthalius no uniform order was observed in this respect. About the middle of the third century, Ammonius of Alexandria, in preparing a Diatesseron or Harmony of the Evangelists, divided the text into a number of very short sections; and these having been adopted with slight variations by Eusebius (4) (whence they are frequently denominated *κεφαλαια Ammoniano-Eusebiana*), they were in many manuscripts conjoined with the Euthalian divisions. In the sixth century, some finding use for a division of the text into larger portions, introduced the arrangement by *τιτλοι* or *breves*; but in the course of time these two modes led to so much confusion that in the thirteenth century Hugo de Santo Caro, a Spanish cardinal, introduced as a remedy the division into chapters and verses, which was afterwards perfected by Robert Stephen into that now in use. Besides these divisions, there was another for church purposes into *περικοπαι*, *αναγνωσεις*, or *αναγνωσματα*, containing the sections of the New Testament appointed for lessons in the public service of the church on Sundays and festivals. The commencement of each of these was marked with an *α* (*αρχη*), and the close with a *τ* (*τελος*) (5).

These historical facts are of service in determining the age of the New Testament codices.

The MSS. containing the New Testament, in whole or in part, at present known to scholars is very great, upwards of 1400, including Evangelistaria, or copies of the Gospels transcribed for use in the churches, and containing the *περικοπαι*, or portions to be read in the service; and Lectionaria, which differ from the Evangelistaria only in that they contain portions from the Acts and the Epistles, in some cases along with those from the gospels. Of these codices, 41 are uncials, written from the fourth to the tenth century. The oldest is believed to be the Codex Vaticanus (B),¹ containing the Gospels, Acts, Catholic and Pauline

Epistles, of which a facsimile has been issued at Rome, edited by the famous Cardinal Mai, and published in 1858 in 4 vols. folio, which comprise also the LXX. version of the Old Testament. Next to this in age comes the Codex Alexandrinus (A), long believed to be the oldest: it is preserved in the British Museum, and has been published in facsimile under the editorship of Charles Godfrey Woide, London, 1786; and still more accurately, along with the Old Testament, by Henry H. Baber, 4 vols. folio, London, 1816-28. This MS. contains the whole of the New Testament except Matthew i.-xxv. 5; John vi. 50, viii. 52; and 2 Corinthians iv. 13, xii. 6. It is ascribed to the second half of the fifth century. To the same century belong three others: the Codex Ephraimi (C), or the Parisian palimpsest (Cod. Par. Rescript. Cod. Reg. 9), so called because over the original writing some treatises of Ephraim the Syrian have been inscribed, and because it is preserved in the Royal Library at Paris; edited in facsimile by Tischendorf, Lips. 1843. A palimpsest containing 28 leaves, over-written in Armenian characters, comprising the Gospels, Acts, and fragments of Paul's Epistles, brought by Tischendorf from the East, and published by him; and a MS. (T) belonging to the college of the Propaganda at Rome, containing fragments of three chapters of John's Gospel. Of the other MSS. it may suffice here to mention only the following:—Codex Bezae, or Cantabrigiensis (D), a MS. of the middle of the sixth century, formerly in the possession of the reformer Beza, and sent by him as a gift to the University of Cambridge, containing the Gospels and Acts, edited in facsimile by Th. Kipling, Cantab. 1793, 2 vols. folio; Cod. Claromontanus (††D), also formerly possessed by Beza, containing the Pauline Epistles, belonging to the second half of the sixth century, edited in facsimile by Tischendorf, Lips. 1852; three fragments of a MS. (N), on purple parchment with gold letters, preserved at Rome, London, and Vienna respectively, edited by Tischendorf, Mon. Sac. Ined., 1846; Cod. Basilensis (E), containing the four Evangelists, with a few gaps; Cod. Augiensis (F) inter Codd. Paulinos), purchased by Richard Bentley, and presented after his death by Thomas Bentley to Trinity College, Cambridge, containing the Pauline Epistles, nearly entire, in Greek and Latin; Codd. Coislinianus (H int. Codd. Paul.), belonging to the Imperial Library at Paris, of the sixth century; Cod. Cyprius, formerly Colbertinus (K), containing the four Gospels, belonging to the ninth century; Cod. Basilensis (B vi. 27), and Cod. Basil. (B vi. 25), two MSS. belonging to the library at Basle, much used by Erasmus for his edition of the New Testament, of the tenth and fifteenth centuries respectively; Cod. Dublinensis (Z), a palimpsest belonging to Trinity College, Dublin, of the sixth century, edited in facsimile, splendidly but carelessly, by Dr Barrett in 1801.

SECT. X.—Ancient Versions of the Sacred Scriptures.

These may be arranged either with respect to their history, as *immediate* and *mediate*, according as they have been made directly from the originals or from other translations; or with respect to the languages in which they exist, as *Oriental* and *Occidental*. We shall follow the latter arrangement, as the more convenient; at the same time intimating, when it is possible, what place each version has in the former.

I. ORIENTAL VERSIONS.—1. *Chaldaic Targums*. After the return of the Jews from Babylon they brought with

¹ These letters refer to the nomenclature of the manuscripts adopted by Tischendorf.

Scripture.

Scripture. them so much of the language of Chaldæa that they were unable to understand their own Scriptures. Hence arose the necessity of accompanying the reading of these in the synagogues with an interpretation; a practice first introduced by Ezra (Nehem. viii. 8), and which continued to be followed as long as the Jewish service was maintained. These interpretations were at first merely oral, and confined to a literal version of the original into the popular dialect; but gradually they became more paraphrastic, and the idea naturally arose of committing the more valuable of them to writing. From this sprung the Chaldaic Targums, or paraphrastic versions of the Hebrew Scriptures. There is reason to believe that there were written Targums as early as the time of Christ. The oldest now extant is that of Onkelos on the Pentateuch, composed according to some in the first, and to others in the third century of the Christian era. It is the least paraphrastic and the most correct of any we possess. Next in point of age and value is that of Jonathan Ben Uzziel on the Prophets. The Jews make him a disciple of Hillel, and in this case he must have flourished shortly before the Christian era; it is probable, however, that he was somewhat later. His Targum is more diffuse and paraphrastic than that of Onkelos, but contains much that is valuable. Both of these are printed in Walton's Polyglott. The remaining Targums, nine in number, are of comparatively recent date, and of little value. Their renderings are very harsh; and they are filled with idle and foolish fables.

Winer, *De Onkeloso ejusque Paraphrasi Chaldaica*, Lips. 1820; Jahn's *Einleitung*, i, §§ 46, 47; Bauer, *Chrestomathia e Paraphrasis Chaldaicis et Talmude delecta*, 1792; Horne, vol. ii., p. 198, pp. 69-75, 10th ed.; Havernick, p. 328.

2. *Syriac Versions.* Eight versions of the whole or parts of Scripture into the ancient Syriac tongue are known to critics, but of these only two deserve particular notice. These are,—1. *The Peschito*,—that is, *simple* in the sense of *literal* as opposed to allegorical,—not later than the third century, probably as early as the second. It contains the whole Bible, is pure in diction and faithful in version, and appears to have been made immediately from the original. 2. *The Peshoxenian*, so called from Philoxenus, Bishop of Hierapolis, under whose direction it was executed by Polycarp, rural bishop of the same district, A.D. 508. About 100 years later it was revised by Thomas of Harkel (Hercule), from whom this recension came to be called the Harkelensian. Among the MSS. lately brought from the Nitrian monasteries is one containing parts of the four Gospels in Syriac of a version differing considerably from the Peschito, and supposed by some to be still older than it. This has been published by Mr Cureton, Lond. 1858. It contains only the New Testament, and is literal to servility; but its renderings are not good. Its chief value is to the critic, in helping him to judge of various readings.

Hirzel, *De Pentateuchi Vers. Syr. indole*, Lips. 1825; Michaelis, *Introd.*, vol. ii., pp. 4-76; Horne, vol. ii., pp. 320, 75-77, 10th ed.

3. *The Samaritan Pentateuch.* This must not be confounded with "the Pentateuch of the Samaritans," which is merely a copy of the original Hebrew in Samaritan characters; whereas the other is a translation of the Hebrew into the Samaritan dialect. This version bears a strong resemblance to the Targum of Onkelos, and some have even deemed it a translation of that. It is probably, however, from the original, with interpolations from Onkelos, but cannot be dated earlier than the second century.

Winer, *De Versionis Pent. Samarit. indole*, Lips. 1817; Horne, ii., p. 42; Gesenius, *De Pent. Samarit. origine, indole, et auctoritate*, Halæ, 1815; De Sacy, *Mém. sur l'état actuel des Samaritains*.

4. *Other Oriental Versions.* These are,—1. *The Egyptian*, embracing the *Coptic* or *Memphitic*, in the dialect of Lower Egypt, probably of the third century; the *Sahidic*,

or *Thebaidic*, in the dialect of Upper Egypt, ascribed to the second century, and, with the exception of fragments, still existing only in manuscript; and the *Basmuric*, in the dialect of the province of the Delta, Bashmur, on the east side of the Nile. 2. *The Ethiopic*, ascribed to the fourth century, and printed in Walton's Polyglott, but with many inaccuracies. 3. *The Armenian*, made by Miesrob in the beginning of the fifth century,—very faithful, but supposed to be in many places interpolated from the Vulgate. 4. *The Arabic*, comprising the Pentateuch and Isaiah, translated by Rabbi Saadias, Haggaon (called from his birthplace Fajum, the ancient Pithom, Phijumensis), in the tenth century; the Pentateuch in Samaritan-Arabic by Abusaid; the anonymous version of Joshua in the London Polyglott; and the Acts and Epistles published by Erpenius. 5. *The Persic* version of the Pentateuch, by Jacob Ben Joseph, surnamed Dawusi, a learned Jew of the ninth century. All these are mediate versions from the Septuagint or Syriac, with the exception of the Arabic and Persic.

Horne, vol. ii., pp. 226-234; Comp. Walton, *Prolegom.*, ix.-xv.

II. WESTERN VERSIONS.—1. *Greek Versions of the Old Testament.* The most important of these is the Septuagint, as it is commonly called, or more properly the Alexandrian. Respecting the origin and early history of this version much uncertainty prevails, of which advantage has been taken to clothe the whole in the mist of fable. The common story of Ptolemy Philadelphus having sent, at the instigation of his librarian Demetrius Phalereus, to Judea for a correct copy of the Hebrew Scriptures, and for seventy-two men of learning (six out of each of the twelve tribes) to translate these into Greek; of his having shut them up in the Isle of Pharos, apart from each other; and of their having produced versions *verbatim et literatim* the same, is now rejected by all scholars. All are agreed that the date of the version is to be referred to the time of Ptolemy Lagus and his son Philadelphus; but there is a difference of opinion as to whether a religious or a purely literary motive led to its production. Those who take the latter view adopt the testimony of Aristobulus, who ascribes this to the literary taste and desires of Demetrius Phalereus. Those who take the other view are of opinion that the motive prompting to it was the multitude of Jews in Alexandria and throughout Egypt, who were ignorant of Hebrew, and needed the Scriptures in Greek; and that it was undertaken under the auspices of the Alexandrian Sanhedrin or council of the Jews, who probably consulted their brethren in Judea about it, and from whom, being seventy-two in number, in all likelihood the version took its name. It seems evident that the different books were executed at different times and by different persons, from the varieties in point of accuracy and purity which they present, the Pentateuch being the first executed; and that the translators of the Pentateuch were Egyptian Jews, from their introducing into their version many Coptic words, and rendering many Hebrew expressions, not into their Greek equivalents, but so as to give an Egyptian hue to the idea. The version thus executed soon acquired great vogue, not only in Egypt, but also in Palestine, where, in the days of our Lord and His apostles, it had mostly superseded the use of the original Hebrew. In the Christian church it acquired the same reputation. Few of the Fathers understood Hebrew, and consequently almost all their quotations from the Old Testament are made through the medium of the Septuagint. The best editions of this version are those of Grabe, Oxon. 1707, 1709, 1719, 1720, 4 vols. folio and 8 vols. 8vo, reprinted, with the addition of various readings from the Vatican manuscript, by Breitinger, Tiguri Helvet., 1780-31-32, 4 vols. 4to; of Bos, Franqueræ, 1709, 4to; of Holmes, vol. i., Oxon. 1798, vols. ii.-v., edited

Scripture. after Holmes's death by J. Parsons, Oxon. 1818-1827, folio; and of Tischendorf, 2 vols., Lips. 1856.

See Aristæ, *Historia de Legis Div. ex Heb. Lingua in Græcam Translatione per LXX. Interpretes*, Frankfort, 1610; Van Dale, *Dissert. super Aristæam de LXX.*, Amstelod 1705; Josephus, *Antiq. xii.*, c. 2; Hody, *De Bibliorum Textibus Original.*, Oxon. 1705; Walton, *Prolegom.*, ix.; Toepler, *De Pentateuchi Interpret. Alexandrinæ indole*, Halæ, 1830; Horne's *Introduction*, vol. ii., p. 203, pp. 47-55, ed. 1856; Havernick, p. 300.

Of the other Greek versions, eleven in number, we have only fragments or traditional information. That of Aquila, a proselyte Jew of Sinope, a city of Pontus, was executed in the first century, and was preferred by the Jews to the Septuagint; it is very literal and Hebraistic. That of Symmachus, an Ebionite, time uncertain, seems to have aimed chiefly at elegance and purity of style; it is very free. Between these stands that of Theodotion, also an Ebionite, and nearly contemporary with Aquila; more elegant and idiomatic than that of Aquila, more literal and correct than that of Symmachus. All of these aim at greater closeness to the original than the LXX.; sometimes they all three agree against the LXX. These, with three anonymous versions, enumerated as *editio quinta, sexta, and septima* respectively, were included by Origen in his splendid work the Hexapla, a sort of Polyglott, which that distinguished Biblical scholar drew up for the use of those who wished to understand accurately the Old Testament, and which contained in parallel columns the Hebrew in the original character, the same in Greek characters, and the Greek versions above enumerated, including the Septuagint. The versions designated as *ὁ ἑβραῖος, ὁ Συρος, το σαμαρειτικόν, ὁ ἑλληνικός*, are known to us only from being occasionally referred to on the margins of manuscripts. The extant fragments of these versions may be found in the sixth volume of the London Polyglott, under the title of *Flaminii Nobilii Notæ*, and in the edition of the Septuagint by Bos.

Dathe, *Diss. Phil. Crit. in Aquilæ Reliquias*, Opuscula, p. 1, &c., ed. Rosenmüller, 1796; Walton, *Prolegom.*, ix.; Horne, vol. ii., p. 216.

2. *Latin Versions.* Translations of the Scriptures into the Latin tongue from the LXX. began to be executed at a very early period, for the benefit chiefly of the Christians in Africa, and those parts of Europe where that language was used. Some have supposed that, as early as the second century, there was a commonly received or authorized version in the Latin churches, but this opinion is hardly tenable. All we know for certain is, that there was one which bore the name of *Itala* which was preferred by Augustin to the rest. Of this ancient version a few fragments are still extant. Towards the close of the fourth century Jerome set himself to revise and correct these versions, and in pursuance of this design issued revised editions of the Psalter, the books of Chronicles, Job, and the writings of Solomon. Unfortunately, the manuscripts containing his revised copies of the other books were lost, either through negligence or fraud on the part of some one to whom he had entrusted them. Satisfied, however, that something more than a correction of existing versions was necessary, he undertook a new translation from the original; and this he executed at intervals, and in the order in which particular books were requested by his friends. At first his undertaking was viewed with no small jealousy, and even St Augustin sought to discourage it, from a fear that a new translation, especially one from the Hebrew, would shake the faith of the ignorant in the certainty of Scripture; nor was it till the sanction of Gregory the Great had been given to it that the version of Jerome was able entirely to supersede the old *Itala* (1). This version is that commonly denominated the *Vulgate*, of which the Council of Trent decreed an immaculate edition; a decree which gave rise to a Papal dissension, to which Christians

have not been slow to point as fatal to the claims of the Scripture. supreme pontiff to infallibility (2).

2 See James, *Bellum Popale sive Concordia Discors Sæti V. et Clementius VIII. circa edit. Hieronymianam*, London, 1600, 4to, 1678, 8vo.

3. *The Gothic Version.* Of this, which was executed by Ulphilas, bishop of the Gothic tribes in Wallachia, about the middle of the fourth century, only the four Gospels, part of the Epistle to the Romans, and fragments of the other Epistles and of the Old Testament, are extant; the first in the famous Codex Argenteus, a manuscript in silver letters of the fifth or sixth century; the second in a Codex Rescriptus belonging to the library of Wolfenbützel; and the third in certain Codices Rescripti recently discovered by Mai in the Ambrosian Library at Milan. This version appears to have been made from the Greek, and particularly from the Constantinopolitan text, but to have been subsequently altered after the Vulgate. The best edition of the gospels is that of Lye, Oxon. 1750, 4to. The fragments were edited by Knittel in 1762, 4to, and by Ihre, Upsal, 1763, 4to, by Mai in 1819, and by Castiglioni in 1829-39, and the whole by Gabelentz and Loebe, 1836-46.

Horne's *Introduction*, vol. ii., p. 240; Hug's *Introduction* (Eng. trans.), vol. i., p. 487; Schott, *Isagoge*, p. 613.

4. *The Anglo-Saxon Versions.* The history of these is by no means accurately known. It appears that, as early as the year 709, the Psalter was rendered into Saxon by Adelm, Bishop of Sherborne. A few years later Aldred, who styles himself "Presbyter indignus et miserrimus," "over-glossed in English" the Latin of a copy of the four Gospels, which had been written by Eadfrith, bishop of the church of Lindisfern, "out-attired, and blazoned as well as he could," by Ethilwold, bishop of the land of Lindisfern, and "smoothed, ornamented, and overgilded," by Billfrith the anchorite (1). Nearly about the same time Beda translated the whole Bible into Saxon-English. About two hundred years after this the Psalter was translated by King Alfred. A Saxon translation of the Pentateuch, Joshua, part of the books of Kings and Esther, is attributed to Ealfric, Archbishop of Canterbury, in 995. The entire Anglo-Saxon Bible has never been published. Alfred's Psalter was edited by Spelman in 1640; and a translation of the Gospels made from the old Latin of the Itala has been thrice edited (2). The best edition is that of Thorpe, London, 1842.

1. See Henshall's *Disquisition* prefixed to his edition of the Gothic Gospel of St Matthew, with the corresponding English or Saxon, &c., London, 1807, 8vo.

2. Newcome's *Historical View of the English Biblical Translations*, p. 1, Dublin, 1792; Horne's *Introd.*, vol. ii., p. 246.

5. *The Slavonic Version.* The authors of this version were Cyrill of Thessalonica, and his brother Methodius, who in the ninth century introduced the gospel among the Slavonians inhabiting Moravia. It seems to have been made from the Greek, and from manuscripts having the Constantinopolitan text. It embraces the whole Bible, and has been frequently printed.

Henderson's *Biblical Researches and Travels in Russia*, pp. 60-102, London, 1826; Horne's *Introd.*, vol. ii., p. 245.

These ancient versions are useful, both to the critic and the exegete: to the former, as supplying not a few various readings which are wanting in all or in most of the codices containing the original text, as serving to determine more accurately the age and country of any particular form of the text, and as helping to confirm or refute particular readings occurring in the Greek codices; to the latter, inasmuch as every faithful version is not only a perpetual

Scripture. interpreter of the sentiments of the original into another tongue, but the authors of these ancient versions, from the time in which they lived, and the locality they inhabited, had peculiar advantages, both philological and historical, for the successful interpretation of the sacred books.

Ernesti's *Principles of Interpretation*, by Terrot, vol. ii., p. 146.
See on the whole of this section, Davidson's *Biblical Criticism*, p. 206; Tischendorf, *Proleg. in Nov. Test.*, p. 228, ff., seventh edition.

SECT. XI.—*Quotations by the early Ecclesiastical Writers from the Sacred Scriptures.*

Besides the object to which these have been already applied, as showing the authenticity of the sacred documents, they serve also a useful purpose to the critic, in furnishing him with numerous readings, in assisting to determine the age, origin, and country, of remarkable readings, and in illustrating the whole history of the Greek texts of Scripture. Care, however, must be taken to discriminate between passages quoted freely from memory, or adapted to the construction and sentiment of the writer himself who quotes, and those which are formally cited from the codex. We must also be sure that the work in which the quotation occurs is genuine, and that the common text of the places in which the citation occurs is correct.

Ernesti's *Principles of Interpretation*, by Terrot, vol. ii., pp. 90–113; Schott, *Isagoge*, p. 629.

SECT. XII.—*Laws for the Determination of various Readings.*

1. That reading is to be regarded as true which is supported by far the greater number of copies and witnesses; but still readings supported by a few books are not entirely to be disregarded, especially when they harmonize with the *usus loquendi* of the author. 2. That reading which the better copies exhibit, unless special reasons prohibit it, is to be preferred to the one which the inferior copies exhibit, although most numerous. Neither the antiquity nor propriety of a reading, solely considered, always proves it to be a true one. 3. That reading which is more harsh, obscure, difficult, unusual, or delicately chosen, if supported by the authority of a proper witness, is preferable to one which is plain, easy, usual, and common. 4. That reading which approaches nearest to the popular and familiar method of speaking, if it be supported by external testimonies, is preferable to one which is more artificial and subtle. 5. The shorter reading, when supported by testimony of importance, and if not incongruous with the style and design of the writer, is preferable to a more verbose one. Still there are cases where the more copious reading is to be preferred. 6. That reading which gives the best sense is peculiarly preferable. But to determine this, the nature of the whole passage, and the genius of the writer, not the mere opinions and sentiments of particular interpreters, are to be consulted. 7. The reading which produces an unworthy or incongruous sense is to be rejected. Good care, however, must be taken not to condemn a reading as unworthy or incongruous which a more correct grammatical and historical investigation would prove to be true reading, or at least a probable one. 8. A reading which agrees with the *usus loquendi* of the writer is preferable to that which disagrees with it. It must be remembered in judging here that the style of an author sometimes varies with increasing age. 9. A reading is to be rejected in respect to which plain evidence is found that it has undergone a *designed* alteration. Such alteration may have taken place, *first*, from doctrinal reasons, Mat. i. 18; Mark viii. 31, xiii. 32; *second*, from moral and practical reasons, Mat. v. 22; *third*, from historical and geographical doubts, Mat. viii. 28, comp. Mark v. 1; *fourth*, from the desire of reconciling passages inconsistent with each other, Mark viii. 31; *fifth*, from

Scripture. desire to make the discourse more intensive,—hence many emphatic readings have originated; *sixth*, from the comparison of many manuscripts, the readings of which have been amalgamated; *seventh*, from a comparison of parallel passages. Corrections of the more celebrated manuscripts have been sometimes detected. 10. Various readings are to be *rejected* which spring from the mere negligence of copyists, and from those errors which are very common in all kinds of books. To these belong, *first*, the commutation of unusual forms for those of the common dialect; the Alexandrine or common form, however, has the preference over others in the New Testament; and this dialect itself also admitted some Attic forms: *second*, the commutation of single letters and syllables, by an error of either the eye or the ear; the former resulting from obscure and compendious methods of writing, or from the similarity of certain letters, such as A Δ Λ, O Θ, &c.; the latter from copying after the reading of one who was misunderstood, or who read erroneously: *third*, the commutation of synonyms: *fourth*, from transferring into the text words written in the margin of copies, and thus uniting both readings, James v. 2: *fifth*, from the omission or insertion of a word or a verse, by an error of the sight: *sixth*, from the transposition of words and passages, whence it may have happened that some error has crept into most of our books: *seventh*, from words which ended with the like sound, or appeared alike; and from proximate words, one ending and the other beginning with the same syllable; *eighth*, from incorrectly uniting or separating words, which naturally resulted in some cases from the ancient method of *continuous writing*: and, *ninth*, from an erroneous interpolation and distinction of passages. 11. A reading is to be rejected which plainly betrays a gloss or interpretation. This may be a word or a whole passage. Sometimes these glosses are united to the true text, and sometimes they have thrust it out. All interpretations, however, are not spurious glosses; for authors themselves sometimes add them, in order to explain their own language. 12. Readings deduced merely from versions or the commentaries of interpreters are to be rejected.

To these which are taken with a few alterations from Beck's *Monogrammata Hermeneutices, Libb. Nov. Test.*, Lips. 1803, may be added the rules laid down by Tischendorf, the greatest living authority on such points, for his own guidance as an editor of the New Testament. These are: 1. Readings are to be held doubtful which are peculiar to one or other of the codices, or which betray in what seem classes the predominant influence of some learned man. 2. Those are to be rejected which, though supported by several witnesses, are manifestly or probably the result of an error on the part of the scribes. 3. In parallel passages, as well of the Old as of the New Testament, and especially of the synoptical Gospels, which the ancients were very anxious to render uniform, those witnesses which preserve a discrepancy are to be preferred to those which present a consent, unless some grave reason persuade otherwise. 4. That reading is to be preferred which seems to have given occasion for the others, or which contains the elements of them in itself. 5. Those are to be studiously retained which are commended by the analogy of the Greek dialect proper to the authors of the New Testament, and not less those that are commended by the usage of any one of them. (*Prolegomena*, p. 32.)

Scrofula
||
Scudéri.

SCROFULA, or KING'S EVIL, a tedious and multi-form disease, of which one of the most characteristic marks is a tendency to a swelling of glandular parts, which, when they come on to inflammation and suppuration, discharge an unhealthy, curdy, mixed matter, and form ulcers very difficult to heal. This tendency to glandular swelling is the mark of a peculiar constitution, derived from parents or ancestors, or acquired afterwards during life; and in such constitutions, the diseases and accidents that happen with comparatively little inconvenience to others, are productive of very troublesome and alarming consequences to them. Scrofulous persons, though frequently very beautiful, are seldom robust or able to endure much fatigue. The hair in scrofulous children varies very much in colour; the body is generally pale and flabby, and the belly prominent; the upper lip is tumid; digestion is generally bad; the voice is husky, and there is great liability to colds, with sore throat and enlarged tonsils. Those who are obliged to live in damp, uncomfortable dwellings, exposed to many privations, who are badly clothed, who live on scanty and unwholesome food, deprived of exercise in the open air, and who are inattentive to cleanliness, are the most subject to this disease. Scrofula is one of those diseases that are manifestly hereditary; and families that are scrofulous ought to be particularly careful as to the way in which they bring up their children. Long and anxious inquiries have satisfied medical men, that scrofula is a disease of debility; and that while everything is to be avoided which has a tendency to over-stimulate and inflame the system, such diet and regimen are to be adopted as have the tendency to strengthen and invigorate it. Children who show any predisposition to scrofula, should be brought up on plain, but nourishing and easily digestible food, such as good broth, with a moderate allowance of solid meat.

Scrofula generally first shows itself between the third and seventh year of a child's age; but it may arise at any period before the age of puberty, after which it rarely makes its first appearance, at least externally. The attacks of scrofula usually begin some time in winter or spring, and get better, or disappear in summer or autumn. The first appearance of the disorder is the occurrence of small round tumours under the skin of the neck, about the ear, or below the chin, without any pain or discolouring. In some cases, the joints of the elbows or ankles are the first parts affected. After some time, the tumours acquire a larger size, the skin which covers them becomes more purple and livid; and they inflame, suppurate, and break into little holes, from which a mixed pus-like fluid, intermixed with curdy-looking matter, at first proceeds, which soon changes into a thin serous discharge. In some scrofulous habits, the eyes and eyelids are the principal seat of the disease, shown by the incessant inflammation of the ball, and the raw and painful state of the eyelids. The bones of scrofulous persons are liable to disease, namely, to partial or general enlargement, to inflammation, suppuration, and exfoliation. Diseased spine is also much connected with a scrofulous constitution. Many internal parts, also, are subject to disease in scrofulous habits.

The constitutional treatment, which is by far the most important, should be as healthful and invigorating as possible; good diet, air, and exercise, are necessary; a residence in the country, or sea-bathing, are useful auxiliaries. Sponging the skin with tepid salt and water, or the use of cold sea-water, if it can be borne, followed up by diligent rubbing with coarse towels and the flesh-brush, is most beneficial. The bowels must be regulated, and occasional doses of rhubarb and grey powder may be useful. A steady and long-continued course of tonics and alteratives will do most good in the way of medicines. Great benefit is often derived from taking cod-liver oil.

SCUDÉRI, GEORGES DE, a French litterateur, was born at Havre, in Normandy, about 1601, where his father held

the post of governor. He at first followed the profession of arms, but subsequently, in 1630, exchanged the sword for the pen, and took to the writing of dramas. He rose to a wide notoriety, and could, at one time, count more admirers than Corneille, the greatest dramatist of France. But men's minds gradually changed, and Corneille is now recognized as the greatest tragedian France has known, and Georges de Scudéri is entirely forgotten. De Scudéri could not bear the rising reputation of his rival; and on the publication of the *Cid*, so strong was his vanity and so urgent his animosity, that he wrote *Observations sur le Cid*, in which he laboured industriously to tear to pieces that superb drama; but its author could afford to smile on all such petty animosities, and he contented himself by a stinging epigram, which he flung at the head of the "solemn fool," his late friend, De Scudéri. He got into disrepute; and despite all the exertions of Cardinal Richelieu, he could not regain his position with the French public. He was appointed governor of Notre Dame de la Garde, a small fort situated on a rock adjoining Marseilles; but he soon returned from that retirement, and died at Paris, on May 14, 1667, after having been elected a member of the French Academy in 1650.

His plays, which number sixteen in all, are as follows:—*L'Amour Tyrrannique*; *Armenius*; *Orante*; *Lygdamon*; *Le Vassal Généreux*; *Le Trompeur Puni*; *La Mort de César*; *L'Amant Liberal*; *Didon*; *Eudoxe*; *Andromire*; *Axiane*; *Le Fils Supposé*; *Le Prince Deguisé*; *L'Illustre Bassa*; *La Comédie des Comédiens*. He likewise wrote *Poesies Diverses*, Paris, 1649; and an heroic poem, called *Alaric, ou Rome Vaincue*.

SCUDÉRI, MADELEINE DE, sister to Georges de Scudéri, was born at Havre on the 15th of June 1607. Few names in literature have afforded a subject for more frequent epigram than that of Mademoiselle de Scudéri, and few works are now less read than hers. Having gone to Paris shortly after she had finished her education, she became connected with the Hotel de Rambouillet, where she met with many persons of the first reputation. Mademoiselle de Scudéri had not resided long among this distinguished circle, when she began to use her pen, to correct, if possible, the wrongs which fortune had done her. Her principal romances are:—*Ibrahim*, 4 vols., Paris, 1641; *Artamène*, 10 vols., Paris, 1650; *Clélie*, 10 vols., 1656; *Almahide*, 8 vols., 1660. She likewise wrote a great many volumes of *Conversations*, besides some fables in verse. She at once met with a great success. Not that this prosperity arose from any very remarkable method which the fair writer had adopted in the construction of her tales; on the contrary, they were about as full of rhodomontade as could well be conceived; but then they were love all over. No doubt she has given us tolerably exact portraits, so far as they go, of the chief *habitués* of the Hotel de Rambouillet; but the attention of the reader is constantly confounded by the unceasing interruption of episodes, anecdotes, and frivolities, and his patience is quite exhausted by the elaborate exquisiteness with which everything is gone about, from the fastening of a shoe-buckle to the decorating of the person of a hero with his coat of mail. No doubt, all this was infinitely admired by the elegant beauties among the Parisian bluestockings; and there were numbers of the other sex down upon their knees before the writer, who was by no means a miracle of beauty. This method of writing was the rage of the day; and there was just one man then living who had the audacity to hold up the whole tribe to the unmitigated laughter of the citizens of Paris. The *Précieuses Ridicules* of Molière sent a shaft through the heart of these absurd coteries, from which they never afterwards recovered. Mademoiselle Scudéri was held in the highest honour by these "Précieuses" till her death, which occurred on the 2d of June 1701, in her ninety-fourth year.

Scudér.

SCULPTURE.

Sculpture. SCULPTURE (Lat. *sculpto*, to cut out, to carve), the art of cutting or carving any substance into a proposed form. In its strict sense it is confined to carving, but in the fine arts it is generally applied to all those processes by which the imitation of objects is effected. First, in carving proper; also in modelling, or the plastic art; in ordinary casting; and in founding or metal-casting, and in gem-engraving.

Carving, as is well known, is simply the art of cutting any comparatively hard material by the best-adapted instruments, as chisels, gouges, files, &c., into different shapes. Modelling is practised upon soft and yielding substances, as clay or wax, which are formed into the desired shape by the hand and different kinds of modelling-tools, generally made of boxwood or ivory.

Every substance that could by possibility be used for carved works has been employed by sculptors of all times. Among the Egyptians especially the hardest were preferred, as basalt, porphyry, and granite; though they also worked extensively in other materials. Marble, various kinds of alabaster, stone, ivory, bone, and wood of all kinds, were used according to circumstances. The variety of marbles is almost infinite. Pliny (*Hist. Nat.* xxxvi. 7) supplies us with an interesting catalogue of those most generally employed. The chief Greek marbles were the Parian and the Pentelic. The former was found in the island of Paros, whence its general name; but it is also alluded to as the marble of Marpessus, from the particular mountain where it abounded. Its colour is a warm or creamy white, and it is remarkable for a sparkling quality in its crystals, from which it is supposed it received its epithet of *lychnæum*. The Pentelic marble came from Mount Pentelcus, in the neighbourhood of Athens. Its colour is white, but it often has blue or gray, and even green streaks running through it, which give it a cold tone compared with the Parian marble. The ancients also much esteemed a marble procured from Mount Hymettus in Attica. It bore a close resemblance to the Pentelic. A great quantity of this marble was imported into Italy after the conquest of Greece by the Romans. A marble of Thasos was also much used, but more for architecture than for sculpture. It was employed for baths, fish-ponds, and for encasing buildings. Italy produces very fine marble. That spoken of as the marble of Luni was procured from the range of mountains near which are situated the modern towns of Massa and Carrara. It does not appear that it was known, or its quarries worked, before the time of Julius Cæsar, in the century before the birth of Christ. In many respects it is superior to the Parian and Pentelic marbles. The grain of the Carrara marble is finer than that of Greece, and its colour, when pure, is a rich white. Remains of the former working in the quarries of Luni may be traced; and it is thought the material was of a somewhat finer texture than the more modern produce. The Carrara marble, now so generally used by sculptors, is not often found quite pure in very large blocks. Veins and spots of gray and blue-black, and red and yellow streaks (probably oxides of iron), occur in it. The quality varies also in different quarries. Occasionally large crystals are found which resist the chisel. The Romans procured white marble from some quarries they worked in Africa. Marble is no longer procured, except by mere accident, from Greece; and the only supply for general purposes of sculpture is from the above-named source, the mountain quarries in the duchy of Massa and Carrara, on the west coast of Italy. Among the varieties of wood used by the ancients for sculpture, the oak, cypress, cedar, box, sycamore, pine, fig, and ebony

occur. Pausanias mentions, in his Travels in Greece, numerous statues made of wood. This to us apparently humble material seems to have been employed for statues of the most elevated personages. The above writer mentions, among several, those of Apollo Archegetes and of Diana Limnitis, which were of ebony. The statues of Castor and Pollux, with those of their children and of their mothers, in the temple dedicated to Castor and Pollux at Argos, were also made of this material. At Lacedæmon was a statue of Venus of cedar. In the treasury of the Sirgonians, at Altis, was a statue of Apollo made of box. Pliny (*Hist. Nat.* xvi. 40) especially mentions cypress, cedar, ebony, and box for their capability of resisting the effects of time; and he says cedar was on this account preferred for images of the gods. Yet all these works have perished, notwithstanding the above writer's anticipation of their everlasting durability, when he says, "*materiæ ipsæ æternitas*." Some figures of small dimensions have been found preserved in tombs. They are of great antiquity, and chiefly represent Egyptian idols. The material of which they are made is usually sycamore wood.

For ordinary casting, as well as for founding (metal-casting), all materials were used that were capable of being solved and again hardened, whether by the action of heat or by mixture with liquids. Among these may be mentioned gold, silver, iron, tin, copper, lead, and their compounds (as bronze), among the metals; and wax, plaster, and stucco among the inferior materials. The ancients used a composition called *electrum*, which was a mixture of gold and silver, in the proportion of one of the former to five of the latter. Helen is said by Homer to have dedicated a cup made of electrum, of the exact size and form of one of her breasts, in the temple of Minerva at Lindus. That composition which was so extensively used by the ancients for statues,—called by the Greeks *chalkos* (χαλκος), the Romans *æs*, and the moderns *bronze*, from the Italian *bronzo*,—is a mixture of copper and tin, with sometimes small portions of other metals. The composition of this material, so extensively used by the artists of antiquity, appears to have been a subject of great care. There were rival schools for its preparation. Pliny especially records those of Ægina and Delos; and says (*Hist. Nat.* xxxiv.) the highest honour was given to that of Delos, and the next to the Æginetan bronze. The mere list of names of the different kinds of bronze known to and used by the ancients is curious. Pliny says there was rivalry (*emulatio*) between two of the greatest sculptors of the best period of the art in the material each employed. Myron used the bronze of Delos, Polyclethus that of Ægina. Besides these bronzes of Delos and Ægina, there was the Corinthian; that of Tartessus; then another kind called the "*æs Demonnesium*;" also the "*æs nigrum*" (black), and the "*æs candidum*," or light-coloured, supposed to have had silver in it. There was also a bronze of a liver colour, called "*æs Hepatizon*," which probably resembled the brown or true bronze colour of the *cinque cento* works. There were other modes of working in metal besides casting used by the ancients. Such was the solid and the hollow hammer-work (*σφυρηλατον*) described by Pliny and others. The earliest metal-works were doubtless produced in this way. There were various modes of exercising this art. Pausanias saw several works of the kind, and explains the different processes. Pliny also furnishes some very curious information upon the subject. Either solid pieces of metal were beaten into shape, and fastened together by means of pins or keys; or the metal was beaten out into plates, and then worked into

Sculpture.

Sculpture. the desired form over a core or nucleus of wood. A small head of Osiris, in the British Museum, exhibits an instance of this practice. The form is bronze; and the centre of wood, is still remaining. Of entirely solid statues, Pliny¹ mentions an interesting example in the statue of Diana Anaitis. Other instances might be quoted, but the above are sufficient to prove the practice. Ancient authors allude to some very remarkable effects produced by the mixture or fusion of metals, by which the complexion of the countenance could be given. Callistratus speaks of a bronze statue of Cupid, by Praxiteles, on the countenance of which was a vivid blush. He mentions another, by Lysippus, in which the cheeks were coloured like a rose. Pliny refers to a statue of Athamas sitting overcome with remorse after the murder of his son; and, says the artist, in order to express the effect of shame, had mixed iron with the bronze, which caused, "by its redness shining through the bronze," the appearance of a blush. Pliny does not say he saw this work himself. Plutarch, again, refers to a statue made by Silanio, of Jocasta dying, and tells us that by a peculiar mixture of the metals used a cast of paleness was given to the complexion. Too much dependence must not be placed upon these general statements. That the works above referred to, and others that might be mentioned, exhibited colour is likely enough; but that those tints were produced in the way suggested, namely, by the fusion of metals, is next to impossible. Neither of these writers were practical artists, and, except Callistratus, they lived very long after the times at which the works they describe were executed. Silanio, for instance, flourished about 320 B.C.; Plutarch, who describes his work, between five and six hundred years later. These accounts, then, so far as they assert that these expressive tints were produced by any possible fusion of metals, are not deserving of credit; but as indirect testimony to the ancient practice of colouring sculpture, they may require further consideration in the course of our history. The Egyptians, according to Pliny, coloured their bronzed statues after they were cast, and the Greeks may have done the same. The method above described, of producing various tints of colour, is quite distinct from the Toreutic art (*Τορευτική*) of the ancients. This seems to have been the combination of distinct materials, always including metal, worked or chased together. The shield of Achilles, as described in Homer, exhibiting different colours, may most probably have been an example of Toreutic art. There are instances existing of inscriptions, in a different metal from the statue, being inserted into the figure. Cicero in (*Verr. Or. iv.*) speaks of an Apollo inscribed thus with the name of its author Myron. There is a bronze statue in the Musée in Paris of a youth, on the left foot of which are the remains of two Greek words in silver letters. Many examples occur of the introduction of foreign substances, either metal, precious stones, glass, or paste, in statues and busts of the best period of Greek sculpture. The practice is not limited to the eyes, but instances occur of the lips being thus inlaid. There are examples of it in the fine collection of bronzes in the Museo Borbonico at Naples, and some instances may also be seen of it in our national collection in the British Museum. Among barbarous nations the introduction of varied and rich materials and colours is universally met with in their sculpture. It might cause surprise to find the same custom patronized among the refined Greeks when their art had reached its highest perfection, if it were not known that certain forms of art were prescriptive, from their antiquity, and that in all works connected with religion (and almost all sculpture was directly or indirectly so applied) the artists were bound by established regulations, strictly en-

forced by the priests and supported by public opinion. Before quitting this branch of our subject, referring to combinations and mixtures of materials, it may be right to notice that, when different kinds of stone or marble were used in the same work, it was called *poly lithic* sculpture; to distinguish it from sculpture in one kind of marble, which was called *monolithic*. Marble and bronze and wood were occasionally used in these combinations.

For modelling, clay, stucco, plaster, and wax were used. Works of great antiquity formed of these substances are still preserved in the different museums of art. Models in clay were usually dried and then baked in an oven, by which they became as hard as stone, and were very durable, as they were unaffected by atmospheric changes. Moulds were then made, by a similar process, into which soft clay could be pressed, and objects were thus multiplied with facility. Clay thus treated is called *terra-cotta*. The ancients must have used it extensively, as may be seen from the countless number of figures and reliefs, lamps, architectural ornaments, vases, domestic utensils, stamps, and other objects which exist, and are still constantly being found in this material. Usually such works are of small size; but there are some statues in the museum at Naples which prove it was also used for statues of large dimensions. There are two figures there, especially deserving attention, of Jupiter and of Juno, full life-size; also two others about four feet high, with masks, representing an actor and an actress, which probably formed the decoration of a theatre. The specimens in England of ancient *terra-cottas* are for the most part of small size. They are chiefly reliefs. Some of those in the British Museum are, however, extremely interesting, both for subject and execution. As such works were usually, if not always, designed for architectural decoration, it is probable they were painted. They were first washed with a thin coating of stucco, and the colour was then laid on with a brush, the preservation of the original surface evidently not being considered of importance. This at least appears to have been the process, judging from several remaining specimens. The employment of wax for modelling and casting is very ancient. Roman families of distinction preserved a collection of statues and busts of their ancestors, which, on particular occasions, were carried in procession at certain festivals or ceremonies: these were sometimes dressed in real drapery. Pliny (xxxv. 2) alludes to this employment of figures of wax. Plaster or stucco is found in the ornamental parts of buildings. At Pompeii there were, some few years ago, two stucco *bassi-relievi* of considerable size and of good design, on the outer walls of a small inner temple in the court of the temple of Isis. The material was extremely hard, and the colour a creamy white. We possess several specimens of the stucco-work of the ancients in the British Museum. They exhibit great delicacy and sharpness of execution. Many are painted, red being the prevailing colour.

Statues were not only made of the above-named materials, but occasionally of those which would seem to be but little adapted to the purpose. There was a statue of Augustus of amber. Statues were also sometimes made of gum and aromatic substances, as well as of others of a combustible nature, to be used on particular occasions. Even hay is mentioned. At the funeral ceremonies in honour of Sylla statues of this kind were used. Sometimes strange conceits were illustrated in these performances. There is mention of a statue of Venus, the fascinating goddess of beauty and love, made of loadstone, which attracted to it a figure of Mars made of iron.

Having made these few preliminary observations upon the materials used for sculpture, it may be proper to describe

¹ "Aurea statua nullâ inanitate, in templo Anaitidis posita," &c. (*Nat. Hist.* xxxiii. 4.)

Sculpture. briefly the different modes of practice. *First*, there is the representation of insulated objects, whether in single figures or groups. As these may be seen all round, like the statue of the Apollo or the Gladiator, or the group of Laocoon and his sons, such works are technically called in sculpture "in the round." When objects or figures are attached to a background, they are called "in relief." The degrees of relief are defined by modern writers and artists by the expressions *alto* or high relief, *basso* or low relief; and the Italians have used a middle term, *mezzo-relievo*, which is intended to describe something between the two extremes. However slightly a figure may be attached to a plane behind it, the mere fact of its touching it constitutes it a work in *relief*. There is a peculiar mode of working in relief chiefly found in Egyptian sculpture. The outline is sunk or hollowed slightly into or below the surface of the ground, and the figure is then formed and rounded on the principle of a very flat *relievo*. Of course, in this mode of execution there is no projecting part above the original plane of the material. It is, in fact, a kind of relieved *intaglio*; but, unlike works in legitimate *intaglio*, the forms are correctly relieved or rounded within the limits described. In *intaglio* all the sinkings are inwards, as is seen in seal engraving, and have not their true appearance till an impression of them is taken.

Various speculations have been offered with respect to the comparative antiquity of sculpture and painting. The story of the daughter of Dibutades having traced the outline of her lover's profile cast by shadow on the wall, and this outline having been afterwards filled in with clay by her father, would give the priority to drawing; and it seems obvious that drawing must be antecedent to modelling or carving in *relief*. But it is probable that *insulated* objects were made in the earliest times. The above is simply a Greek traditional romance; and, referring to a circumstance of comparatively late date, cannot be taken as historical authority for the origin of sculpture. There can be little doubt that rude attempts at forming clay or any other plastic substance into defined shapes were amongst the first exercises of the natural imitative faculty of man. The comparatively easy task of copying the real form of an object to representing its partial appearance by lines on a flat surface, suggests the inference that this must have been the earliest mode of imitation.

The attempts of some, indeed most, writers on art to trace the origin of sculpture to a common or single source have not led to any satisfactory results. The great antiquity of the art renders it most difficult, in the first place, to trace its backward history through the obscurity of ages; but the difficulty is further increased when the question arises, whether it is quite reasonable to attribute its origin to one nation, from which all others have necessarily derived its practice. The faculty or desire to imitate is instinctive in man; and the earliest nation, therefore, would probably have first exercised this natural tendency. When we come to consider sculpture as a refined art, we must seek further for the principles which gave it its distinctive character than in the mere bald fact of a people having imitated objects by form. There can be no doubt that the intercourse of nations had its influence on the style of any existing art; or, where it was not known, that its practice may have been introduced; but the discovery of specimens of rude imitative art in countries that cannot by any apparent possibility have had communication, proves that its existence in its primitive forms may have been quite independent of any such intercourse. When the very late date of the oldest ancient writers who refer to the history of sculpture, compared with the undoubted remote antiquity of the art, is taken into consideration, there is enough to account for the difficulties they had in collecting any evidence to be relied on upon this intricate subject.

Sculpture. Where the writers are Greeks, the bias in favour of their country's glory would lead them to lay stress upon every little tradition that would flatter their patriotism. Of this the inventions and works of art attributed to one Dædalus afford an instance, and show the limited knowledge that existed of the first artist who is noticed in the annals of Greek sculpture. The progress and improvement of various useful arts must have been gradual, and due not to one, but to a series of ingenious artists and inventors. These, however, have all been attributed to one individual, who bore a name which, in all probability, was a general appellation given in early times to any workman or artificer remarkable for his skill. In the same manner, we find the introduction into Italy of the simple art of modelling attributed to one Demaratus, a fugitive from Corinth, about 600 B.C. He was accompanied, it is said, by two artists, Eucheir and Eugrammus; whose names appear rather to be epithets of skill than the simple names of persons. Again, some ancient images are spoken of as having fallen from heaven; showing, unless this is to be treated in the same way as some similar modern instances of superstitious credulity, how little real historical knowledge existed of the origin of the earlier sculpture. This is not the case at a later period, when the art held a more defined position, and when, fortunately, epochs in its history were marked by changes in style which enable the archæologist to classify schools and fix important dates. Passing by, then, the first rude attempts at mere objectless imitation, the inquiry into the history of sculpture as an art having a definite purpose becomes a subject of great interest.

The desire to record in some palpable form the memory of extraordinary events and persons, and to hand down to posterity some enduring monument of the great or useful deeds of benefactors, was doubtless the first impulse which led to the use of sculpture. The first works applied to these objects were probably of the rudest description, and will not come under the conditions of art. Still, from these simple beginnings we probably may trace the development of great results. The oldest histories make mention of what may truly be called monuments erected to mark the scene of any remarkable incident. They were composed simply of heaps of stones, sometimes of blocks of large size; but even these rude forms indicated at a later time ideas of pregnant meaning. A heap of stones was set up at Bethel by Jacob, to mark the spot where he had seen the vision of angels ascending to heaven (Gen. xxviii. 18). The agreement or covenant entered into between Jacob and Laban was recorded in the same simple way, by a pillar and heap of stones (Gen. xxxi. 44). A similar monument was built over the grave of Rachel; and other instances of the kind might easily be quoted. Pausanias (vii. 22) mentions, that as late as A.D. 170 certain of the divinities of Greece were worshipped under the form of mere columns or blocks of stone set upright.

The tradition handed down from generation to generation of feats of arms, the prowess of a warrior, or of the founder of a nation, led in all probability to the first attempt at individualizing in some way the representation of the hero whose fame was thus repeated from mouth to mouth. The people, associating with this object feelings of respect and admiration, the transition, or rather development, of the higher sentiment of veneration is easily understood. Profound respect, and the desire to show gratitude for real or supposed benefits, would soon lead to the payment of extraordinary honours; and the elevation of these heroes or public benefactors to the grade of beings above the ordinary class of mortals became the natural course,—especially, too, when the real existence and individuality of the person so honoured had become obscured by the lapse of time. Thus, the record of great and good actions of men

Sculpture. led to hero-worship, and hero-worship further led to giving men the attributes of supernatural beings.

It has been said that the history of sculpture is almost the history of idolatry. It is true in part. Religious feeling had much to do, as will be seen, with the progress of the art in its more advanced condition; but it is probable that the first defined images or statues were of men and not of gods, and that human idols, so to speak, preceded those of divinities. As far as can be ascertained, the heavenly bodies were among the earliest objects of worship among the heathen nations; and the symbols that represented them were most likely merely pillars of a conical or pyramidal form, and not imitations of any human figure. It has been ingeniously supposed (*Landseer, Sabaean Researches*) that when such objects or images are referred to by Moses as "graven," that it is in allusion to signs (or hieroglyphics) that were inscribed or cut upon them. Thus the sun was worshipped at Emessa under the form of a black conical stone, with marks on it to represent that luminary.

The oldest record of the existence of objects which it may be assumed were imitative is in the sacred writings; and the first intimation found of the existence of sculpture, in connection with the idolatrous worship, is among the Chaldeans. Some early Christian writers have declared that Terah, the father of Abraham, made images, but Scripture gives no authority for the supposition. We read, however, that when Rachel, in company with Jacob and Leah, quitted her father's dwelling, she carried away with her certain images upon which Laban set so much value that he immediately followed her in order to recover them. There are no particulars of what these images were like, or of what material they were made. They must have been small and light, from the facility with which Leah contrived to carry them away unobserved, and from the care with which she concealed them, when Laban "searched all the tent, and found them not." Images are referred to in another place, where Jacob is described as taking the "strange gods," and hiding them under an oak (*Gen. xxxv. 4*). In the book of Joshua, allusion is made to the corruption of the Israelites by the superstitions of the people among whom they had so long dwelt, and after the exodus they are solemnly warned against this influence, and exhorted to return to a more pure and simple form of worship.

The earliest known names of sculptors are found in the Old Testament. They are of the artists employed to make the ornaments of the tabernacle. One of them was Bezaleel, the son of Uri, of the tribe of Judah; the other Ahioab, the son of Ahisamach, of the tribe of Dan. Their date, therefore, is about fifteen hundred years before the Christian era. No remains of the sculpture of those early nations are known to exist; so that no useful speculations can be offered upon the character of their arts, nor upon the original sources of their knowledge. Of course, much of their late improvement may be attributed to their intercourse with that wonderful people the Egyptians. That they were considerably advanced in various branches of scientific discovery must be assumed from the accounts handed down to us; and they must have been acquainted with some difficult processes of art to be able to set up the image of the molten calf, and to make the brazen serpent.

The important and interesting discoveries that have been made of late years of the remains of some of the ancient cities of Assyria have opened a wide field of observation to the antiquary, while they have also afforded most valuable examples of the character of the sculpture of that nation. The light these will throw upon the early history and chronicles of this remarkable people can scarcely be over-estimated; and the successful researches of scholars and travellers, amongst whose names those of Rawlinson, Botta, and Layard will always be remembered with honour, are

daily supplying new and most valuable information upon these hitherto obscure subjects. **Sculpture.**

Herodotus had an opportunity of personally inspecting the wonders of Babylon. He speaks of the hundred gates in the walls "all of bronze," and of the temple of Belus, which had bronze gates. He describes also a statue of gold in this temple; the god, he says, was represented seated, and a golden table stood near, and the step or footstool, and the throne itself, were of gold. He alludes also to another statue of solid gold, 12 cubits high; but with his usual conscientious reserve, he admits he did not see this, but only repeats what he was told. Darius, the son of Hystaspes, wished to possess this valuable statue, but did not remove it; but his son Xerxes seized it, and, it is said, slew the priest who attempted to prevent this act of spoliation. Diodorus Siculus refers to numerous works, showing the grand scale of magnificence of the Babylonians, and gives the names of the various sovereigns of the earliest dynasties under whom the respective works were said to be produced. These details are not, however, received by scholars as entirely worthy of confidence; but although much exaggeration may have crept into the account given by Ctesias, from whom Diodorus derives his information, there can be no doubt that the most astonishing splendour and luxury prevailed, especially in the gorgeous decoration of these palaces and other public buildings; and from which it may be inferred that the arts of design had been practised by this people for a very long period. From whence the Babylonians derived their first knowledge of art we at present have no means of judging; and any speculation upon so difficult a subject would carry us beyond the limits to which our immediate inquiry confines us. But without attributing the works mentioned by Diodorus to such a remote date as the earlier Semiramis, recorded by Ctesias, or to that mythical personage Ninus, there can be no question that the arts must have existed in Assyria for a long series of years before they could have reached the high condition described by the various writers referred to.

There is a curious custom connected with the art-practice of the Babylonians at a somewhat later period of their history mentioned by the prophet Baruch, who wrote about 607 B.C. In the sixth chapter (ver. 4-8) he says, "Now shall ye see in Babylon gods of silver, and of gold, and of wood, borne upon shoulders, which cause the nations to fear; they themselves are gilded and laid over with gold, and covered with purple raiment." This practice of using real drapery upon sculpture was not uncommon among ancient nations, and exists even in our own times in some countries.

The most remarkable results of the researches of travellers in Assyria are the extensive sculptured monuments that have been found in the ruins of the ancient Nineveh and neighbouring places. They seem to have been intended to serve the double purpose of decorating rooms and as records of remarkable incidents in the history of the nation, or of the prowess or habits of the sovereign. The most striking objects, from their size and character, are some colossal figures in which the human is combined with the animal or brute type. These are evidently mythological personations, in which the union of intelligence with force is characterised. The grand effect of these gigantic figures is very remarkable; and standing, as they appear to have done, at the entrance to sacred or royal buildings, they must have produced an awful impression on the people. The treatment or art-quality varies in these, showing that some of them were of earlier date than others. Although of very peculiar style, they generally exhibit an intimate knowledge of animal character in the action and expression. Whether the imitation be of the lion or the bull, the animals which occur in these larger works, the individuality of each is successfully marked. There is one peculiarity

Sculpture. which deserves especial remark in the execution of these portal or gate sculptures. Each animal is represented with his fore legs firmly planted under him. In the front view these are clearly defined, but in the profile, from their parallel position, one is, of course, entirely concealed by the other. To obviate the appearance of the animal having but three legs (for of the hind legs one is advanced before the other), a supplementary fore leg is added, which can only be seen when the spectator looks at the sculpture sideways or in profile: all the four legs are then clearly defined. These colossal figures have backgrounds; but the relief from the wall is very high, and they almost have the effect of entire statues. The reliefs that decorated the walls of the apartments represent battles, sieges, crossing rivers, lion-hunting, and endless details of the ordinary occupations of the people. The most minute circumstances are noticed. The vegetation of the country in trees and shrubs is shown, as well as the animals in common use; persons are represented crossing rivers, swimming on skins filled with air; in other slabs are buildings being erected, showing all the implements of the artificers: these objects, with the ornaments on the dresses of people, as well as on the accoutrements of the horses, are all copied with the most marvellous ease and accuracy. The execution of some of these works is also evidence of most skilful practice in the workmen, affording proof, again, of long experience in this class of art. The peculiar mode of treating the human figure shows that here, as well as elsewhere, there was a prescribed form established. However crowded the composition,—whether in the battle-field, or scaling the enemy's walls, or in the hunting-field,—the same outline, as of one family or even of one individual, is met with in all the faces. They also have an expression given them which, it will be seen, is preserved in all early representations of historical and mythological subjects; namely, that of a complacent smile, which lights up the countenance, however seriously or even savagely the person is occupied. This very curious characteristic of all very ancient sculpture will be further exhibited as our history proceeds. Numerous reliefs, and other objects procured from these excavations, are safely deposited in the British Museum; and they afford a most interesting illustration of the arts and habits of a nation whose history is connected with our most serious reflections. Nineveh, it is well known, was utterly destroyed so early as 606 B.C.; so that in these works, allowing for the time necessary for the execution of the latest, we contemplate productions of nearly three thousand years' antiquity. Some of them appear to have been executed at no very long period before the fall of this great city; for, from the inscriptions which have been deciphered, they appear to represent the history and actions of Esarhaddon, who succeeded his father Sennacherib. The latter was, as we read, murdered by two of his sons "as he was worshipping in the house of Nisroch, his god;" and "Esarhaddon reigned in his stead." Others are evidently of a more remote antiquity. The progress that is being made in conquering the difficulties of understanding inscriptions, in a language that has long been obsolete, is daily furnishing new and most valuable information respecting the subjects represented in these reliefs. The slabs are inscribed with letters or characters in close lines, which often pass entirely over the figures. The engraving does not, however, materially affect the sculpture in its general effect; while great advantage may be derived from this double mode of recording events, as each may mutually throw light upon the other, and thus enable scholars to define with greater accuracy the meaning of the whole series of illustrations.

Among the remains of art brought away from these excavations are many of undoubted Egyptian character. These may be considered as quite distinct from the pure or

true Babylonian and Nineveh type. That the sculpture and art generally of each people was influenced by their mutual intercourse may be accepted as a very probable and natural consequence; but a careful comparison of the character of form in the earlier works of both nations seems to exhibit peculiarities which indicate an originality of feeling in both schools; although in a certain quaintness, or primitive simplicity in the composition of the figures, there may be a resemblance between them. These Assyrian sculptures cannot be put forward as successful works of fine art. They are of a prescribed style and type; and though some are of greater excellence with respect to their execution than others, they are of a fixed and not progressive school of art. The superiority observable in some of them is of a practical kind; but there is little feeling for beauty, no improvement in the anatomical construction of the figures, as exhibited in the articulations of the joints, or knowledge in the arrangement and flow of drapery, or in the graceful composition of the groups of figures. Still, they are works of immense interest; and their recovery, after so many ages, is an event of great importance to us on every account. Chiefly they claim the attention of the scholar and the antiquary for the light they throw upon the long-lost history of one of the greatest nations of the earth; but these curious works will also suggest some very interesting subjects of speculation with regard to the influence they exercised on the sculpture of that remarkable people who, long after Babylon and Nineveh had ceased to exist, carried this art to its highest perfection.

It is much to be regretted that no ancient works of Phœnician art remain. It may be assumed, however, from their geographical position, and the constant intercourse that existed between the several nations which were located between the two great rivers of Assyria and the sea-coast, that such sculpture as they had must have partaken of the general character of the art above described. The enterprise and skill of the Phœnicians gained for them especial notice at a very early period. Homer speaks of the Sidonians as remarkable for their skill and ingenuity, and calls them *Σιδόνες πολυδαίδαλοι* (*Il.* xxiii. 743). A Phœnician artist of Tyre was selected to execute some of the most important works required for the temple built by Solomon. This king, we read (2 Chron., and 1 Kings vii.), applied to Hiram, King of Tyre, for workmen, and he sent him "a cunning man, skilful to work in gold, silver, brass, iron, stone, and timber." The temple was built about one thousand years before the Christian era. The position of the Phœnicians gave them the command of the commerce of the ancient nations, and they extended their dealings to the most remote known boundaries of the earth. There is no doubt that at an extremely early period they traded with the British Isles, and procured tin from Cornwall, the Cassiterides of the ancients; while the coast trade of all the nations of the Ægean and Mediterranean seas must have been in their hands. Tyre is finely apostrophized by the prophet Ezekiel with reference to its great commercial importance. He calls it "the merchant of the people for many isles:" "the ships of Tarshish," he says, "did sing of thee in thy market; and thou wast replenished and made very glorious in the midst of the seas." Carthage was a colony of Phœnicia; but although there are coins existing of this settlement, they are of too late a date to throw any light upon the true early art of their ancestors.

The history of sculpture receives little assistance from the remains of art found in Persia. There is no trace of any original design among them, and the earliest monuments bear so close a resemblance to those of Assyria, both in the character of the forms and in the types, in the arrangement of reliefs against the walls and entrances flanked by gigantic winged animals with human heads, and other peculiarities, as to leave no doubt of their derivation.

Sculpture. It is thought that the earliest existing remains of Persian art are the buildings of Persepolis, and that these are to be attributed to the date of Darius, or about that time. The art of the Persians has, however, some peculiarities that so far give it a character of its own. The processions of warriors, captives, tribute-bearers, and others, are in every respect similar to those found at Nimroud and Khorsabad; but while the Assyrian dresses show no movement or folds, the Persian work exhibits these accidents in the draperies. The conquests of the Persians over the Egyptians, and their intercourse with different parts of Asia Minor, would account for some slight changes in their art, but sculpture was never developed by the Persians into an art of beauty. Strong national prejudices prevented this, and led at one time to the destruction of the works of art they met with in other countries. Xerxes was instigated to destroy the temples in Greece, because it was urged it was impious to inclose within walls the immortal gods, whose appropriate temple or dwelling-place is the entire universe; and statues were defaced under the same feeling of religious prejudice. Under these circumstances, notwithstanding the great interest and importance that must attach to the history of this great nation, in its influence upon those countries with which it became associated, Persia cannot take the position of a school of sculpture in the sense in which that term may be applied to Assyria, Egypt, and various parts of Asia Minor, where the art had a distinctive character.

There is no temptation to dwell upon the sculpture of Hindustan or China. It affords no assistance in tracing the history of the art, and its debased quality deprives it of all interest as a phase of fine art, the point of view from which it is here to be considered. It must be admitted, however, that the works existing have a sufficiently distinct character to stamp their nationality; and although they cannot tempt the historian of art to dwell upon them, they offer very curious and important subjects of inquiry to the scholar and archæologist, who may trace their influence in regions where it is difficult to conceive these nations could ever have penetrated. The sculptures found in India, at Ellora, Elephanta, and other places, are of a strictly mythological character. They usually consist of monstrous combinations of human and brute forms, repulsive from their ugliness and outrageous defiance of rule and possibility. They are remarkable for their extent and their dimensions, many of the works being colossal; and they often are elaborately ornamented, the carving being very careful and minute. The striking feature in these works is that which pervades nearly all the monuments of the East,—vastness of scale, and a tranquil character of expression. Repose, unless in exceptional cases, where the actions of gods or heroes are being represented, seems to be the ruling sentiment of all early sculpture. The above remarks are intended to apply to the art of the Hindus. Of ancient Chinese sculpture much less is known, from the difficulty that hitherto has existed in penetrating into the interior of the country.

What has been observed above of Hindu and Chinese sculpture, in its relation to the history of the art, is equally applicable to the quaint and grotesque specimens that have been met with by modern travellers in some parts of South America. There is sufficient in their design and execution to make them objects of great interest to the inquirer into the early history of the localities in which they have been found, but they afford no indications at present to guide the archæologist in connecting them with the progress of art. They exhibit proofs of considerable facility in execution in the artists who produced them: an argument for their long practice; but of their real date it is almost impossible to form any acceptable conjecture.

The sculpture of the Egyptians, though it never reached the perfection the art attained in Greece, has great claims

on our attention. The extent of their works in architecture, painting, and sculpture, of an antiquity so remote that it seems to defy research, and exhibiting at the same time all the characteristics of long practice, show that this remarkable people were an established nation at a very early period in the world's history. When Abraham visited Egypt he found there an organized form of government; and the most ancient sacred writings speak of the "wisdom of the Egyptians." These old traditions of the learning, the prowess, and the greatness of this people are daily receiving confirmation from the discoveries of modern travellers and scholars; but still it seems impossible to penetrate the darkness which obscures the earliest history of the nation. The dates of the foundation of some of their most celebrated cities, as Thebes and Memphis, can only be conjectured, no sufficient authority having yet been discovered among the monuments or inscriptions for fixing their precise era. The sculpture and other remains found at Karnak, a portion of Thebes lying on the Arabian or eastern side of the Nile, bear inscriptions in which is read the name of Osirtasen, who is said to have been contemporary with Joseph, above 1700 B.C.; and some of the ruins are believed to be of a date long antecedent to that king. Wilkinson (*Ancient Egyptians*, vol. i.) considers the pyramids to the north of Memphis to be the most ancient monuments in Egypt, and probably of the world, and thinks they were erected about 2120 B.C.

The characteristics of Egyptian sculpture are very peculiar. It exhibits extreme simplicity of design, great breadth of treatment, to the exclusion generally of minute details, and a solid largeness of form. There is little or no variety of expression in the heads, especially of the superior personages represented: a benignant, placid smile appears on all the countenances. Where dress is introduced, there is no composition of drapery in the way of movement, nor any indication of folds. The action of the figures, however important or exciting their occupation, is limited by the most severe conventionalism. If sitting or standing, they have the legs parallel, the arms close to the sides, while the heads always look directly in front. Our national collection of antiquities boasts some extremely valuable examples of Egyptian sculpture, and the student may easily consult original specimens, by which he may become acquainted with the style of art of this extraordinary school. Considering the great antiquity of the Egyptians, and their long duration as a nation,—taking into account, too, the various fortunes of the country, both from their own conquests and from the invasion of foreigners,—it is remarkable how little change occurred in the leading characteristics of their art. Whether the monuments be of the most remote archaic period, or of the more recent ante-Roman time, no sufficient alterations were introduced to destroy that peculiar and distinctive character which stamps all Egyptian art with its national individuality. Certain antiquaries have attempted to define marked epochs in the history of Egyptian sculpture; but, though certain changes may be detected in the mode of representation in monuments attributed to different dynasties, they do not afford sufficient authority for anything like a strict chronological classification. From the high finish and more careful execution of the works of the time, it is thought that the national prosperity, and therefore the condition of art, were highest during the reign of Rameses, about 1350 B.C.; and, judging from other remains, that the country and its art were most depressed from the date of the Persian conquest; that is, from 525 to about 414 B.C. Of the latter fact there cannot be any doubt; and although the nation freed itself after a time from the hateful rule of Persia, Egypt never again recovered its ancient renown, nor did she long retain her national independence.

The attachment of the Egyptians to that peculiar style

Sculpture.

Sculpture. which has made their art so remarkable, may be traced to the same influence that was exercised on all the earlier nations where sculpture was employed for religious purposes. It was a means of direct appeal to the prejudices and the understanding of the people, and, as such, was used and controlled by the ruling powers. This power was exercised in Egypt by the hierarchy, and, as the kings or Pharaohs were also priests, all the acts of the sovereign were associated in the public mind with sacred influences. Thus the conquests of the king in battle, the submission of foreign nations, the paying of tribute, the execution of prisoners and captives, were all represented in their sculpture and painting, with the accompaniments of overruling divinities, either expressed in form or implied in emblems. The decorations of tombs were also equally associated with these feelings; and the solemn, colossal statues of lines of kings, attended by the most sacred symbols of their mythology, made the most profound impression upon a population which, from its earliest infancy, had been educated to believe in the divine appointment of its rulers. In art, then, the priesthood permitted no innovations; and the division of the population into castes or callings secured among the artists, who no doubt were especially attached to the sacerdotal institutions, a strict conformity to established types. According to a passage in Synnesius, the profession of an artist was only allowed to be exercised by persons properly qualified, lest, in ignorance, they should transgress against the old laws which regulated the representation of the gods and sacred subjects. Plato also says the artists were not allowed to innovate; "hence the art remains the same, the rule of it the same." This, then, may be taken as the real cause of the long duration of Egyptian art under its peculiar form or style. Some stress has been laid on the recorded fact, that the Egyptians were ill-favoured in point of personal attractions; and that they were without the advantages enjoyed by the Greeks, of having public games and exercises. But even if these statements of the want of beauty among the general population are trustworthy, they are insufficient to account for the stationary condition of their sculpture. The true ground of the unprogressive character of their art, as regards its style, is found in the nature of their institutions. That the Egyptians were not incapable of conceiving an *ideal* of beauty, is shown in some of the heads of colossal and other statues that have reached us, where, within the limits to which we have adverted, a very decided character of beauty of expression, and even of form, is met with. No better example of this can be found than in the head, in the British Museum, of the (so-called) young Memnon; but which, more probably, is a portrait of Rameses II.¹

The Egyptian artists employed every available material for sculpture, with the exception of iron. For colossal works they used basalt, porphyry, granite, lime and sandstone, alabaster and wood; for smaller works, ivory, alabaster, and various metals. Clay was also extensively used, baked, and covered with a peculiar vitrified varnish, which was burnt into them. Figures, and animals, and other objects, worn as amulets, or used as lares or household gods, executed in this material, abound in all collections of Egyptian antiquities. The remarkably clean and finished execution observable in Egyptian sculpture in the hardest materials—basalt, granite, or of other substances most diffi-

cult to deal with—has always excited the attention of the curious, as a proof of the wonderful proficiency of this people, even at a very remote date, in some of the processes of handicraft, and especially in the hardening of the metals of which their tools was made.

Sculpture. With respect to the origin of the nation, and of the character of its religious sculpture, it is almost useless to offer any conjecture. Such authority as can be derived from analogy, from indirect testimony, and also from great care in examining the peculiarities of their monuments, would strengthen the belief that the grand and simple scheme of their art, as it is exhibited in the massive architecture of their temples and other public works, and in the colossal scale and severe tranquillity of their statues, claimed kindred with the Asiatic nations. The most important settlement of the Egyptians seems to have been in the Thebaid or Upper Egypt; and it is supposed that civilization advanced northwards from thence. To the south was the country called in the Scriptures and in the Egyptian language the "foreign land of Cush;" and its natives, with whom the Egyptians were constantly waging war, are generally represented in the monuments as captives or as bearers of tribute to the Pharaohs. They were a black people, and of distinct physical character from the Egyptians; and, as is proved by the difference in the form of the skull of the two nations, of a totally different race. Without speculating upon the origin of the more civilized and intelligent people by whom the inhabitants of Upper Egypt were eventually subdued, the above simple facts are sufficient to establish the belief in the colonization of the Thebaid by a foreign, and, in all probability, an Asiatic race.

The next school of sculpture which demands notice in the history of the art is the Etruscan. Of the earliest inhabitants of this portion of Italy nothing is certainly known, though the subject has occupied the attention of the learned of all times. The architectural remains which are found scattered about that which was considered Etrurian territory, are evidence of a very remote antiquity, but no examples of imitative art can be assigned to the earlier period of the existence of this people. Whether the first colonization was from the east or from the south, from Phenicia, from Asia Minor, or from Egypt, it is at present impossible to determine. The colossal character of construction, observable in their building of the Cyclopean walls, still remaining, is characteristic of the earlier erections of all these nations. In the greater part of the works in sculpture that have reached us there is undoubted evidence of Greek influence, though in the style there is an exclusive and individual character; but it must be admitted also that there are examples of sculpture as well as of painting in tombs, evidently of a very remote antiquity, and that appear to be quite original in their subjects, and, as far as we can judge, totally independent of Greek fable and mythology. It has been a common error to suppose, because the earlier works of different countries show considerable resemblance in their forms, that it is an indication of their derivation from a common source, and the more archaic sculptures of Greece and Etruria have been frequently confounded, from the supposed similarity of style; when, after all, as has before been observed, this is only the common, characteristic of all art in its first stage. This fancied resemblance to some of the Egyptian figures led at

¹ As reference has been made to the collection of Egyptian antiquities in the British Museum, it may be useful to those who desire to study the sculpture from the original monuments, to point out the grand divisions of the arrangement in these galleries. The northern gallery and centre contain the sculptures of the 15th dynasty, which comprehends the most splendid epoch of Egyptian history. It is the era of Rameses, who appears to have been the Sesostris of the Greeks. These works are of the fourteenth century B.C., and there are others of older date. But little change, if any, was made during the Persian rule in Egypt. In the southern gallery are deposited works of this period, and of the Græco-Macedonian period, after the conquests of Alexander the Great and the succession of Ptolemy Soter, 323 B.C. Afterwards commence the sculptures of the Roman period, after the capture of Alexandria by Augustus, 30 B.C., extending down to the Mohammedan invasion, 640 A.D.

Sculpture. one time to the belief that the Etruscans derived their art from Egypt.¹ Considerable variety will be found in works of the Etruscan school. In some examples the forms are undefined and very simple, and the accessories, as the hair and draperies, arranged stiffly, and in regular lines, bearing in these respects considerable resemblance to the works of the Persians above described. In others there is an exaggeration and affectation entirely distinct from anything found in the contemporary art of the time, excepting, occasionally, in the early Greek vases; a circumstance which might seem to indicate a connection at this period of their history with this nation. The peculiarity referred to is especially indicated in the hands, where the fingers are turned back in the most unnatural manner. The prevalence of a marked style in the Etruscan sculpture may be attributed to the same causes which, it has been shown, influenced Egyptian, Assyrian and, as will be seen, early Greek art. Their rulers, the "Lucomones," were priests as well as governors; and no doubt religious feeling consecrated certain forms, and prevented changes which might have been considered in the light of profane innovation. A distinction must, however, be drawn between original Etruscan works,—that is, the production of native Etruscan artists,—and works in the Etruscan style; a mode of treatment that was retained by the admirers or followers of this school long after the date of the true and original art of Etruria. It was a style particularly distinguished by the Romans, and called by them "*tuscanicus*," as applied to art; and it was not necessarily confined to works executed by native sculptors. All productions which exhibited the hard and dry manner of the earlier Etruscan school gained the title of *Opera Tuscanica*. There is a passage in Quintilian which affords an interesting illustration of this classification of style, when he is speaking of the (technical) character of the works of some of the more celebrated Greek sculptors of the fifth and sixth centuries before Christ. Callon and Egesias, he says, executed their statues or productions in a harder style than some other artists referred to, approaching very near to the Tuscan or Etruscan forms; Calamis, again, was less rigid.² It may be remarked, generally, that the works of the Etruscan artists are deficient in beauty. They have not even that simplicity and repose which, in spite of its deficiencies in other respects, give a certain air of dignity to Egyptian sculpture; still less is there any attempt at or approach to the fine forms of Grecian art.

Some Etruscan works have been found to differ considerably from the usual productions of this school, and from the style particularized in the foregoing remarks. This is especially observable in the compositions in painting and sculpture that have been discovered of late years in certain tombs of Volterra and other Etruscan cities. The sculpture in these consists of semi-recumbent figures reposing on sarcophagi. They vary in size, some being as large as life, others of small dimensions; and they usually form the top or lid of the coffin, or receptacle in which the remains of the deceased were deposited. In these statues we no longer recognise the ordinary Etruscan style; and yet they have been found in localities and bearing inscriptions which would appear to carry them back to a very remote date. The forms usually are clumsy, and they are loaded with full and heavy drapery. The heads, again, are peculiar. They often have all the character of being portraits, and sometimes they are pleasing in expression, and even exhibit an approach to beauty. The first impression they convey is, that they belong to a low Roman school of art, to which

indeed some antiquaries have unhesitatingly assigned them. **Sculpture.** There are, however, difficulties in the way of coming to a conclusion upon their date and origin. There is no doubt that the tombs of Etruria were opened and, in many instances, plundered in ancient times; and it is extremely probable that they were used also as depositaries for the dead by a people who were in possession of the country very long after the date of their original constructors. Objects have been found in some of these tombs evidently of various ages; a proof of their not being in their primitive integrity when opened by more recent antiquaries. From these circumstances, it becomes exceedingly difficult to define the precise age of the works that occasionally are found in them; and where inscriptions of an ancient character occur upon sculpture that exhibits indication of the decadence of art this difficulty is of course greatly increased.

The foregoing rapid survey of sculpture has been rather a notice of an universally practised form of record than a history of a refined art, requiring the exercise of the intellect and the hand, and having for its office to express elevated sentiment, or to illustrate noble subjects under appropriate forms of beauty. Important in other respects as was the employment of sculpture among the most ancient nations, and valuable as are the monuments that time has left us, it was not till the Greek mind perceived its capability of development that the entire value of the art was recognised as a means of physically illustrating the perfection of nature's noblest work. It strikes us now with wonder and astonishment that so long a period could have elapsed between the first invention and rude practice of sculpture, and the perfection it was destined to reach among the Greeks. Sicyon was founded above 2000 years B.C., Argos 1856 B.C., and yet it is not till between 700 and 600 B.C. that those first changes are perceived in the style of art practiced in that region of the world, which then led so rapidly to the consummation of sculpture in the great schools of Myron, Phidias, and Polycletus, in the time of Pericles.

The Greeks were subject to the same obstructive influence of the priesthood as other nations whose works have been referred to, and there can be no doubt that for a considerable period this power of preventing innovation in sculpture intended for religious purposes, as statues in temples, or votive offerings, held its sway, and retarded the progress of the art. But there seems to have been one established quality in the Greek mind which, independently of other circumstances, necessitated, if it may be so said, the development of an imitative art to a condition of high excellence. This was its sensibility to beauty. Some writers, in endeavouring to account for the superiority of the Greeks in art, have thought it attributable to climate, to the government under which they lived, to the beauty of the people, or other external causes; but in considering the history of the several schools of Greece, it will be found that none of these existed universally in any of the localities where sculpture was most successfully practised. Attica, the home of the fine arts, had a climate of great inequality. In some parts there was the greatest luxuriance of vegetation, while in others the soil was ungrateful, naked, and barren. In personal beauty Athens held no decided superiority over other cities, and yet the Athenians were distinguished beyond all others for their productions of art. It certainly is curious that not one of the women whose celebrity for beauty has come down to us was a native of Athens.

¹ Cicognara very properly remarks,—"*La supposizione che gli Etruschi traessero dagli Egizi le loro arti e il loro disegno è priva di fondamento, poichè, come avvertì il Lanzi, la rigidità e il rettilineo dei segni non hanno bisogno di venirli dal Nilo, e nei principii delle arti presso tutte le nazioni si vede lo stesso carattere, essendo quello stile non tanto arte quanto mancanza di arte.*" (Cicognara, *Stor. della Scultura*, vol. i.)

² *Duriora et Tuscanicis proxima Callon et Egesias; jam minus rigida Calamis, &c.* (lib. xii. 10).

Sculpture. Phryne was of Thebes, Glyceræ of Thespiæ, Aspasia was born at Miletus, Laïs at Hyccara in Sicily; and when Zeuxis the painter was occupied upon his famous picture of Venus, it is recorded that he studied the beautiful forms of seven virgins of Crotona. It is worthy of remark that Cicero, speaking of the youths he saw at Athens, says he observed few who were handsome. (*De Nat. Deor.* ii., c. 79.) It is not intended to deny the existence of beauty among the Athenians, but simply to point out that their exclusive possession of it was not necessarily the cause of their success in sculpture. Indeed, the Lacedæmonians, whose admiration of beauty is especially remarked by Ælian (*Var. Hist.* xiv. 27), proscribed the practice of sculpture and the fine arts in Sparta. Nor will the form of government account for the excellence of this people in the arts of design. The most different political conditions existed where the arts flourished, as was the case at Corinth, at Athens, and Sicyon. The aptitude of the Greeks for excelling in the fine arts is then to be sought for in causes different from, and independently of, the above. It is more probable that it was owing to the peculiar constitution of the Greek, one of whose prominent features was an extreme sensibility to beauty. It was the development of this feeling that established a principle upon which their imitative art was founded, and which led necessarily to its excellence. Why the Greek was the first to feel this power, and how he was led to break through prescriptive forms in expressing it in art need not now be discussed, but the fact is indisputable. He recognised sculpture as an imitative art, and his acute and sensitive intelligence taught him that it was capable of improvement from the old types if that upon which it was founded, namely Nature, was carefully studied and copied. This was the secret of the superiority of the Greeks; and their selection or choice of what was most fit to be copied led to the perfection of their sculpture, and to the establishment of what has been called in art-language, *ideal Beauty*.

It has been observed that the Greeks seem to have had an intuitive perception of the beautiful; that they sensibly appreciated it is proved by many curious facts. Allusion has been made to the admiration felt for it among the Lacedæmonians (*Athen.* xii. 12). In other parts of Greece the same feeling existed. The priests of the temple of Jupiter at Ægium in Achaia, were youths who had received a prize for their personal beauty. The same distinction marked the priests of the Ismenian Apollo; and the boys who took part in the procession in honour of Mercury at Tanagra, were also chosen for the possession of this quality. (*Paus.* ix. 10, 22; vii. 24). The Thebans had a law which subjected artists to a fine if they represented objects less beautiful than they were in reality (*Ælian Var.* iv. 4; and see Junius *de Picturâ veterum*, and Lessing, "Laocoon"). It is remarkable how strictly the artists seem to have been bound by this principle not to represent repulsive subjects, nor indeed to express any passion or feeling under forms that were incompatible with the laws of beauty. The habits of the Greeks fostered this appreciation of the beautiful. The mode of life of the people, and the constant occurrence of public exercises, taught all classes to be judges of the human figure. The gymnasia, or schools for training for the games, were universally frequented. The public found there their rulers, statesmen, philosophers, poets, and artists taking interest in the exercises; and thus all were accustomed to see the human form in its highest condition, whether in action or repose. The education or training of young men who intended to take part in the great contests for prizes, was also a subject of the greatest care. The fullest development was given to the muscles, and constant practice prepared them for those trials of agility and strength which were witnessed by the eager multitude of all classes, and

from which the successful candidate issued not only a crowned victor but the subject of the poet's noblest odes, and of the sculptor's art. The highest honour that could be awarded, and this was only granted to those who had been conquerors a certain number of times, was to be allowed to dedicate an Iconic or portrait statue, representing the fortunate candidate, in the Altis or sacred grove, near the temple of the Olympian Jupiter. These statues were seen by the crowds who assembled periodically to witness or take part in the games; and thus was the memory of the prowess or agility of the individual perpetuated constantly inciting others to deserve a similar distinction. The opening afforded by this custom for the exercise and improvement of sculpture is obvious. These statues were portraits of the individuals who had gained their crowns by the exhibition of their superiority in certain exercises. Thus the sculptor found in the successful wrestler a peculiar development which was evidence of strong physical power; in the victor in the foot race the clean limbs and light proportions which enabled him to outrun his competitors; while the combination of similar qualities of strength and lightness gave the type of the general athlete. Here, then, are seen the elements of those fine creations which have stamped Greek sculpture with its enduring character of excellence. From such studies were produced the statues of Hercules and others of that class, or those of the light and active Mercury, or, again, the Discoboli and similar productions; and from the skilful application of the principles discoverable in such forms, the whole class and variety of ideal subjects, either of sublimity or beauty, in the statues of divinities and heroes had their existence. The noble objects to which sculpture was thus applied, to do honour to worth, and to decorate the temples of the gods, gave a dignity to the art, and an honourable character to the pursuit, while the recognition of the principle, that an imitative art was constantly to aim at reproducing and repeating the finest forms which were presented for its guidance, led to its perfection as an objective art. It was precisely this union, which had not before been established by any nation of artists, which gave to Greek sculpture its extraordinary excellence; and it may be said has maintained the superiority of Greek art through a long succession of ages. No mechanical copying of Greek statues, however skilful and however zealous the copyist, can ever secure for modern sculpture the same noble and effective character it possessed among the Greeks, for the simple and intelligible reason that the imitation, close as may be the resemblance, is but the result of the eye and hand, while the original was the expression of a true and deeply-felt sentiment. Another circumstance highly conducive to the progress and development of art must also be taken into consideration. This was the general appreciation of sculpture among a whole people sensitively alive to beauty in all its forms. Art was not here sustained by the patronage of the few who, having, or affecting to have, what is called *taste*, bought the services of the sculptor, and paid him to decorate a gallery by order. In Greece the artist, himself a Greek, having a common feeling for the beautiful with his countrymen, produced his works for the public; they were to be erected in places of honour, to be dedicated in the temples of the gods, and no small motives influenced his labours. These were the conditions which carried the art to its highest perfection. When they were invaded, and the objects of art lowered to suit a change of feeling sculpture, as will be seen, immediately began to show symptoms of decline.

The history of the earlier settlements in Greece is involved in so much obscurity, that it will scarcely answer any useful purpose here to attempt to penetrate it. We must be satisfied to trace, so far as is practicable, the first germ of art, and to follow it in its various phases from its rudest

Sculpture. condition to its perfection, and then to its extinction. The earliest records which can be at all associated with sculpture, or as the elements of its creation, were as simple among the Greeks as with other nations. Columns and blocks of stone were the primitive types under which they worshipped their divinities; and as late as Pausanias, A.D. 170, some of these were to be seen in different parts of Greece. This traveller speaks of seeing some at Pheræ in Achaia. It is recorded that Juno at Thespiz, Diana Patroa, and the Milichian Jove at Sicyon, and even the Venus of Paphos, were thus represented. The addition, by degrees, of heads, and then of feet and hands, the latter close to the sides, and the legs united like columns, formed probably the earliest attempt at giving such objects a human form. These speculations are, however, but vague, and it would be difficult to attribute dates to such early attempts at imitative design. In this respect, in the very infancy of art, the mode of representation was doubtless very nearly the same wherever it was attempted at all.

In tracing the later history of sculpture among the Greeks, certain changes mark distinct epochs in the progress of the art. Four principal periods may thus be distinguished, each characterised by striking peculiarities of style or treatment.

The first may be said to comprehend all that uncertain age of which no reliable record remains, and of which our only knowledge is in the traditions preserved by ancient writers down to the period of the first art-movement exhibited in the archaic-movements of the Eginetan school, at about 600 B.C. The second period extends to the perfection of sculpture, by Phidias and his contemporaries, at from 450 to 400 B.C. The third period includes the practice of the art from this time to about 250 or 200 B.C., when the more voluptuous execution and style of design of Praxiteles and his scholars, and of Lysippus and his followers effected a most important change in the condition of the art. The fourth and, in this comprehensive summary, the last period of true Greek sculpture is that of its decline, under mere imitators or bad innovators; when manner took the place of style, and when that pure simplicity and noble grandeur that had hitherto characterized sculpture were superseded by minute details, mechanical and tasteless execution, and by littleness and poverty of treatment.

In the earliest attempts in sculpture among the Greeks there is a distinction discernible which separates them from those of other nations, and a skilful antiquary will rarely have any difficulty in deciding whether or not the most archaic specimen submitted to his judgment be of this people or of any of the more ancient races who practiced the art. It is true the sculpture of the archaic period offers but little that is attractive to the admirers of the beautiful. Rude and clumsy in form, stiff and limited in action, there is nothing in these respects to elevate them above the earlier productions of other nations. The first improvement was in the attempt to give fuller action to the figures, and this led immediately and necessarily to a more careful consideration of form and knowledge of parts. The characteristics that are here most striking are exaggeration. The action is usually violent and energetic, and the forms are over-developed, full, and charged. The proportions are wide compared with the length of the figure. The treatment of the head in sculpture of the earliest period offers also some remarkable peculiarities. The eye is usually long and narrow, and slightly raised at the outer extremity, and the mouth is open with a smiling expression. The execution of the hair varies at different dates and in different schools. On some of the most ancient coins it is wiry, and in close parallel lines; in other examples the hair is represented in masses, in lumps or knobs. In male figures the beard, and other hair is marked by elaborate care. The drapery

Sculpture. in early sculpture is usually extremely scanty and thin, lying close to the figure, and scarcely showing any fulness or variety except at the edges, which are sharp and angular. The folds are for the most part arranged with mechanical precision; opposite folds corresponding, line for line and angle for angle, with each other, and exhibiting at their termination a regular zig-zag. For examples of the peculiarities above noticed, the student may examine the early tetradrachms of Athens, the early coins of Oreste and Pellene, the coins of Posidonia, the heads of the statues found in the island of Ægina, and the sculpture from Selinunte in Sicily. The British Museum possesses most interesting monuments of these earlier schools, and in the absence of the original works casts from the Selinuntine and Eginetan sculptures may be consulted with advantage. Lately some very curious and interesting monuments of the archaic type have reached this country from Branchidæ in Miletus. Whether they really are of the remote date their general style suggests, or are ancient imitations of an earlier school of sculpture, executed to complete some grand design, for they appear to have formed a portion of an avenue of sitting statues leading to the temple of Apollo Didymæus, may be a question for antiquaries to determine, but they are extremely valuable as examples of the peculiarities of early execution.

The earliest names that occur of sculptors belonging to the Greek school are Dædalus, Smilis, and Endæus. The difficulty of giving anything like precise dates to the first artists who are recorded has already been adverted to, and with respect to Dædalus, especially, this difficulty is the greater because there is every reason to believe that it was a common appellation given to many persons remarkable for skill and ingenuity. The Dædalus usually considered as the first rightful owner of the name is said to have been of a royal race; the grandson of Erechtheus King of Athens. He was the inventor of various mechanical instruments, the lever, the saw, &c.; and as a sculptor was the first who ventured upon the innovation of separating the legs and arms of figures from their former stiff attachment to the body. Pausanias (ix. 3, &c.), says "the ancients called wooden figures Δάδαλα (Dædala);" and he adds that it is probable the artist was named after his works rather than by his own name; thus making Dædalus a title or distinctive appellation from his skilful accomplishments. Pausanias was shown some wooden figures said to be by Dædalus. He declares there was a certain air of grandeur in them, but no beauty. If so, it could only have been from their size, unless his feelings of veneration for their great antiquity gave them sublimity in his eyes. Smilis was a native of Ægina. He was the author of a statue of Juno at Samos. Endæus was an Athenian, and scholar of Dædalus. Pausanias (vii. 5) records a colossal seated statue (of wood) of Minerva Polias, by this artist, which was in the temple at Erythræ in Ionia. He is said also to have executed works in stone and ivory. The accounts of works and of artists of this remote period are of course very vague.

Phido of Argos, about 800 B.C., is said to have struck the first money in Greece, in the island of Ægina. Some extremely rude coins of that island, having for a device a tortoise, are extant; and from the very primitive style of their execution, they have been thought to be not very remote from the period alluded to. At this time mention is first made of statues in metal. Gitiadas, some of whose works Pausanias saw (iii. 17), and Learchus, of Rhegium, are mentioned among the earliest artists, and the above writer speaks of a bronze statue of Jupiter at Lacedæmon, which was said to be by Learchus, as the most ancient statue in that material known to exist. The date of Learchus has been a subject of considerable difficulty with antiquaries, but it is probable that he lived about the time

Sculpture. here stated. The next names that occur are of importance in the annals of Greek sculpture,—these are Telecles, Rhœcus, and Theodorus. Their reputation was so great that they had the credit of inventing many processes of art which it is obvious must have been known before their time; such, for instance, as the plastic art, or modelling. This is recorded by Pliny (*Hist. Nat.* xxxv. 12), though he himself tells us in another place its discovery was attributed to Dibutades of Corinth. This simple art was of course known at the very earliest period, long before either of these artists appeared, but it is probable they were the authors of many improvements by which sculpture was greatly advanced. Rhœcus and Theodorus were natives of Samos. The latter name was borne by two sculptors, one the son of Rhœcus, the other of Telecles. Herodotus (iii. 60) says Rhœcus, who was an architect as well as statuary, built the temple of Juno at Samos; and he is referred to as the author of a statue called Night, preserved in the temple of the Ephesian Diana. Pausanias says he was unable to find any work of Theodorus. Pliny mentions several that were attributed to him. The son of Telecles was considered the inventor of casting in iron. Herodotus (iii. 41), records that Theodorus engraved the celebrated ring which Polycrates, the tyrant of Samos, threw into the sea, and so marvellously recovered. The king, who had enjoyed a long course of uninterrupted prosperity, determined to make some sacrifice to prove his equanimity. Among his most highly-valued treasures was this ring, and he voluntarily parted with it, casting it himself into the sea. His good fortune still, however, attended him, for in a few days a large fish that had been taken was presented for the king's acceptance, and upon opening it the much-prized ring was found in its belly. Theodorus is also said to have made a magnificent vase that was dedicated at Delphi by Crœsus, King of Lydia; a circumstance that has led to the belief that Theodorus lived at a later date than that usually assigned to him. It is possible, however, that the vase presented by Crœsus may have been among the treasures of the king, a carefully-preserved work of an older age, and from its value and the fame of its author, a worthy object for the purpose to which Crœsus applied it. Pliny says these artists lived long prior to the expulsion of the Bacchiadæ from Corinth. This occurred about 659 B.C. It has therefore been conjectured that Rhœcus and the two sculptors named Theodorus must have flourished between 800 and 700 before our era. Dipœnus and Scyllis, who are supposed by some writers to have lived at this remote date, were considered the founders of the school of Sicyon. They had many scholars, among whom appears Leachius of Rhegium before mentioned, and which will account for the early date given to these artists. It has been said of them they were the first who employed marble for sculpture; but the expression of Pliny (xxxvi. 4), upon which this opinion has been formed, more probably means that they were particularly distinguished in working in that beautiful material. Dipœnus and Scyllis were employed to make some statues of the gods for the Sicyonians; but owing to some offence received, they quitted Sicyon, leaving the statues unfinished. A famine soon after afflicted the country, and the oracle declared it would not cease till the statues of the gods were completed. The sculptors were prevailed upon to resume their work, and the statues of Apollo, Diana, Hercules, and Minerva, were finished by them. Among their scholars are Tectæus and Angelon, Doryclidas, Dontas, Medon, and Theocles. (Paus. ii. 32; iii. 17, &c.) Some writers have imagined that these eminent sculptors lived as late as 540 B.C. Flaxman (*Lect.*, p. 75-79) considers the older date the more probable one.

From the most archaic period to about 600 B.C., there probably was but slight change as regards style in sculpture, though no doubt improvements were effected in some of the

executive processes. At the later date referred to, a great **Sculpture.** step was made in the art; and it will be seen that from this time, from 600 or 550 B.C., the advancement of sculpture was continuous and rapid to a degree that is perfectly surprising.

Before proceeding with the consideration of some of the more interesting of the earlier monuments discovered within the present century, attention may be directed to the ancient lions over the gate of Mycenæ, supposed to be the oldest example existing of Greek sculpture. The work is in stone, in high relief. The two lions are represented, on their hind legs, with the front feet resting on the shaft of a column standing between them. Pausanias (ii. 16) says this was reputed to be the work of the Cyclops. The statues from Branchidæ have already been referred to for the peculiarities they exhibit of archaic design. It remains to mention the very interesting archaic sculptures discovered in Lycia in 1842-7, and now deposited in the British Museum. The statues and reliefs in this collection are of different periods, down to a comparatively late date, but the slabs on the tomb (called) of the Hæpies, and some few fragments of draped statues, are of the most ancient type; curiously illustrating the infancy of Greek sculpture, and its distinctness of character from that of any other people.

In alluding to certain characteristics of archaic treatment in style, especial reference has been made to the sculptures of Selinus and Ægina. The first consist of some fragments of metopes from temples discovered in Sicily in the year 1823. One represents a portion of a combat between a warrior and a female. Three others, from another temple, are of historical or mythological subjects. The art of all these remains is very rude, but extremely curious and interesting, especially with reference to the growing change in sculpture. The proportions of the figures are short. The waists are remarkably contracted, and the heads, thighs, calves, and feet large and heavy. The legs and feet are represented in profile, though the figures are fronting the spectator. The execution of the hair is formal, being long, and falling over the shoulders. It is also in some of the figures plaited. As usual in archaic design, all the figures, whatever their occupation, appear to be laughing. There is a total absence of beauty in all these sculptures. In the head of the fallen warrior some exceptional peculiarities will be observed, which seem to refer to a higher school of art than the others. So strong a resemblance appears in it to some of the heads of the Æginetan sculpture that it might be fancied that a portion of these works may have been superintended by artists from that rising school, while others may have been the productions of native artists. The date of these interesting monuments may probably be reckoned at about 600 B.C. The originals are in the Museum of Antiquities at Palermo, but casts from them are deposited in the British Museum. Selinus was founded about 620 B.C., and though it was taken and sacked by the Carthaginians, was not finally destroyed till about 270 B.C. The above sculptures may be referred to an early period of its history; and the student of the history of the art will be struck with the link they form in the progressive changes which begin now to mark the development of Greek sculpture.

The remarkable series of marble statues that form the Æginetan collection of sculptures, of which also we only possess casts, was discovered in the year 1812 in the island of Ægina. They decorated the two pediments of a temple dedicated to Jupiter Panhellenius. They consist, in addition to numerous fragments, of sixteen statues, of which eleven belonged to the western pediment and five to that at the eastern end of the temple. The first eleven appear to complete the composition required to fill the space, and are therefore considered to be the entire number originally intended on that side. The eastern end is of course very deficient. The subject of both is a combat; and in the more

Sculpture. extensive series Minerva appears in the centre as the presiding power. She is of somewhat larger proportions than the combatants, and is raised on a step or plinth. The goddess is fully armed, with her helmet on, and on her left arm is a large circular shield. In her right hand, which was bent towards her front, was in all probability a spear. Her ægis covers her bust; the edge of it shows the winding bodies of the snakes, and these terminate in small points or tails, which were formed of metal. The figures extended on either side of the centre are engaged in battle; some are in violent action, some wounded and dying. It is remarkable that the figures of the eastern pediment are of a larger scale than those of the western side.

These sculptures offer many points of great interest to the student of the history of Greek art. Their general style may be classed as archaic; but there are peculiarities even here that show the commencement of an important movement. The statue of Minerva is of a much more ancient or rude style than the rest of the figures, from which two important conclusions may be drawn:—*First*, that although all the statues are unquestionably of the same date, there was a style of art known superior to that sometimes practised; and, *secondly*, that in the statues or representations of divinities, the sculptors were under some obligation to conform to prescribed rules. While the combatants exhibit every variety and generally entire correctness of action, the goddess is stiff and primitive, and stands with both feet turned in the same direction, sideways, in an attitude of difficulty and insecurity. In the other figures there is considerable display of knowledge of form, and an approach to broad treatment in the execution; and though the details are not yet equal to the excellence of the subsequent school, there is a fine feeling for proportion, and an agreeable and harmonious balance of parts. Yet here again the archaic element steps in in the character of the heads, which exhibit all the peculiarities of the more ancient types before referred to. However earnestly engaged, and even when wounded and dying, each has a smiling expression; the mouth being slightly open, as though each figure was occupied in the most pleasing manner. The hair is worked with the utmost care, in small curls and knobs, in the manner before described. The execution of these sculptures may be attributed to the age immediately preceding the time of Pericles. The originals in marble are at Munich, but there is a fine set of casts from them in the British Museum.

Before entering upon the sculpture of the great period referred to, a few remarks may advantageously be offered upon the schools and artists immediately preceding. The most celebrated of the former were those of Sicyon, Ægina, and Corinth; and from about 500 B.C. the succession of the sculptors and the changes each effected in the style of his art may be traced with some accuracy. Callon was one of the most celebrated of these, but his precise date is uncertain. After him appear Onatas and Glaucias. The former was both sculptor and painter, and Pausanias describes many of his works (Paus. vi. vii. ix. x.) Amongst these were several of bronze; some of colossal dimensions, and others of ordinary scale. At Pergamus was a colossal statue of Apollo; at Olympia a colossal Hercules, also one of bronze dedicated by the Thasians; also at Olympia a statue of Mercury, placed there by the people of Phe-neos; a statue of Ceres and others. Onatas executed some works in connection with other sculptors: Calliteles, for instance, assisted him with the above-named statue of Mercury. In another work, a chariot with accompaniments, dedicated at Olympia, we find him associated with Calamis; and in another with one Calynthus. Pausanias also states that certain of his performances in the sister art were preserved in the temple of Minerva Aræa. It is curious and interesting to find ancient writers illustrating another art,

that of oratory, by a reference to peculiarities in the practice of sculpture; by which we not only acquire some valuable information upon the subject of change and progress already adverted to, but are furnished with an important list of names of successive ancient sculptors, by whom these changes and improvements were effected. Cicero (*De Clar. Orat.*) says,—“*Quis non intelligit Canuchi signa rigidiora esse quàm ut imitentur veritatem? Calamidis dura illa quidem, sed tamen molliora quàm Canachi; nondum Myronis satis ad veritatem adducta, jam tamen quæ non dubites pulchra ducere.*” &c. &c. We have already seen that Quintilian in the same way characterises the difference of style of artists of this transition period, where he says,—“*Duriora Callon atque Egeas; minus rigida Calamis.*” &c. These notices are extremely valuable. They carry sculpture through various phases, out of the early archaic manner, into the more perfect school of which Polycletus and Phidias were the great ornaments. Cicero, in continuation of this review, says of the works of the former, “*Pulchriora etiam Polycleti (signa et opera) et jam planè perfecta*; thus bringing us through a series of changes to the highest perfection of the art.

A list of names of the eminent sculptors who now crowd the scene, though of great interest to the antiquary, would occupy much space, and would convey but little information upon those points which are important to our history.

There is one, however, noticed in the above series upon whom a few remarks may be made, as we possess in our national collection an antique copy of an undoubted work of the master. This is a statue of a “Discobolus,” or quoit-thrower by Myron. Lucian and Quintilian describe the original, which was of bronze; and the copy we refer to, one of three known to exist, bears out the criticism that is come down to us. The statue is full of action, even to exaggeration, and the style of form and execution associates it with the known date of its author. The ancient comment on it expresses the judgment of the writer:—“*Quid tam distortum et elaboratum quàm est ille Discobolus Myronis.*” &c. Myron and Polycletus were rivals in bronze works, and we read that they had their preferences for the kinds they used. Polycletus employed the bronze of Ægina, Myron that of Delos (Plin. *N. H.*) Myron was an Athenian and a pupil, together with Phidias and Polycletus, of Ageladas. He is said to have introduced a greater variety in his art than those who preceded him; but Pliny says he was not considered successful in expressing sentiment or passion, and that in his style of treatment there was still much of the stiffness of the early schools.

We are now struck with the importance that was beginning to be attached to particulars and details in sculpture; that is, in expression and peculiarities of treatment, apart from the distinct changes in style which indicate the general progress of the art in its passage from the archaic to the perfect schools.

Pythagoras, a sculptor, a native of Rhegium, who lived about the time, is mentioned for his superior ability in this respect. A statue by him is recorded of a wounded man, in which the expression of pain was so accurately defined that the spectators were affected by it, and seemed to share the sufferings of the figure before them. This sculptor is also particularly noticed for having expressed the veins in his statues, and for the careful execution of the hair. “*Hic primus nervos ac venas expressit, capillumque diligentius.*” (Pliny, *Nat. Hist.* xxxiv.)

The next sculptor famous in the annals of Greek art, of whom particular mention is made, is Polycletus. There are at least three of the name recorded, but the most eminent is called by Pliny *Sicyonius*. It is possible, however, as one equally celebrated was also called *Argivus*, that he may have been a native of Sicyon, but was known as an Argive from having produced many of his most celebrated works at Ar-

Sculpture. gos, and thus that the two epithets belonged to the same individual. He is noted for the great care and perfection of his finish; but it is said he wanted variety in his art. This Polyclethus was the author of one statue, a "Doryphorus," or lance-bearer, which was so perfect in its proportions that it was called by common consent "the Canon." Artists referred to it as a rule or standard of art, "*lineamenta artis ex eo petentes velut a lege quâdam.*" (Plin. N. H. xxxiv. 8.) We might easily dwell, if our limits permitted it, upon the numerous works of this accomplished sculptor, who seems to have been highly distinguished in every branch of his profession, and to have been no unworthy rival of the greatest artists who illustrated the age of Pericles. In one process he is pronounced to have surpassed even Phidias himself, for Pliny, in handing down a tradition of the practice of the *Toreutic* art, says that Polyclethus perfected or consummated what Phidias had only commenced. "*Hic consumâsse . . . ut Phidias aperuisse.*"

Ageladas, or, as it sometimes occurs, Eladas, of Argos, produced numerous works of excellence; but the circumstance of the greatest interest attached to his name is his having been the master of the three leading sculptors of the fifth century before Christ, the age of what has been properly considered the *sublime* school of this art.

We now come to the greatest sculptor whose name and fame have reached modern times; and fortunately some undoubted works produced by him, or under his immediate direction, remain to attest the justice of the distinction that has been awarded him. Phidias, the son of Charmidas, was a native of Athens. He was born in the 73d Olympiad, or 484 years B.C. His masters were Hippias, of whom little is known (indeed he is mentioned but by one author), and Ageladas above mentioned. At one time he is said to have studied painting, an art professed by some of his family; but it is as the greatest of all sculptors that the reputation of Phidias has reached modern times. It has been seen by preceding remarks, and may be proved by existing remains, that the sculptors of what has been termed the *Æginetan* school, immediately prior to this time, laid the foundation of a finer style of art which Phidias especially brought to perfection. The preparation for this consummation takes nothing, however, from the honour due to this sculptor; for the superior quality of the art which he produced stamps it with a character of grandeur and beauty entirely its own.

Circumstances were peculiarly favourable to the development of art in the age at which our history has now arrived; and it was fortunate that there were such sculptors and architects as Phidias, Polyclethus, Myron, Praxiteles, Ictinus, and Callicrates to take advantage of and do justice to the opportunities offered for the highest exercise of their talents. It was under the enlightened administration of Pericles that some of the most magnificent works in these arts were produced; and Plutarch records the favour with which Phidias was honoured by this accomplished patron. Speaking of the more remarkable edifices erected during his government, he says, "It was Phidias who had the direction of these works, although great architects and skilful artists were employed under him;" and "Every artist was ambitious that the excellence of the workmanship should equal the beauty of the design." (Plut. *in vit.* Pericles.) Of the greater works for which Phidias is most celebrated there are unfortunately no remains. These were the magnificent chryselephantine statues, with their elaborate accompaniments, which he executed for the Athenians and for the Eleans, and of which accurate descriptions have been handed down from ancient times. The most important was that at Elis of the Olympian Jupiter. The materials, as the term chryselephantine denotes, were ivory and gold, and the accessories were of the richest kind. The god was represented seated on a throne of gold. His brows were crowned with a wreath of olive; in his left hand he sup-

ported a statue of Victory, in his right he held his sceptre. **Sculpture.** His drapery was enriched with objects painted upon it, patterns of flowers and animals. At the foot of the throne were small statues of Victories; and on panels various subjects of ancient poetry and mythology. Nothing can exceed the splendour of the ornamental compositions described as part of this magnificent work. (Paus. v., c. 11.) The colossal proportions of this statue, sixty feet high, compared with the temple in which it was placed, has occasioned a judicious criticism of Strabo. If it had stood up, he says, it would have been higher than the roof of the building, and therefore that the statue was disproportioned to the temple. An interesting anecdote is recorded by Pausanias showing the importance attached by the Greeks to this great work. Phidias, the story says, after the completion of the work, besought a sign from the god in whose honour it had been executed to intimate whether it was acceptable and pleasing to him. A flash of lightning immediately descended into the temple, and struck the pavement before the astonished and gratified sculptor. This was at once hailed as a proof of the satisfaction of the deity, and a brazen vase was placed on the spot to commemorate the circumstance: Pausanias says it was existing in his time. Our limits prevent our describing this work as fully as it deserves; but the reader who desires further and more precise information respecting the mode of execution, the subjects represented in its decoration, and the admiration bestowed upon this celebrated production may advantageously consult the elaborate work by M. Quatremère de Quincy, (*Jupiter Olympien*), in which many very interesting particulars upon the whole question of chryselephantine and Toreutic art are collected. It appears that this magnificent work was existing as late as the fifth century after Christ. The temple of Jupiter Olympius was destroyed about A.D. 385; but the statue had been transported to Constantinople, where it was destroyed by fire in or about A.D. 475. The next great work of this sculptor, executed prior to the statue above described, was that of Minerva of the Parthenon at Athens. This, like the Jupiter, was composed of gold and ivory. The goddess was represented standing, holding in her right hand a statue of Victory, and in her left a spear. She had a helmet on, and on her ægis was the head of Medusa. Her shield was elaborately decorated with a representation of the battle of the gods and giants, and the pedestal exhibited the birth of Pandora. The height of the statue was 39 feet. These statues are here selected for notice as being the most highly-reputed performances of Phidias, but a long list of colossal and other statues, in various materials, as bronze, marble, wood, as well as gold and ivory, by this artist, might easily be produced to show the extent and the important character of his employment. As there are no remains of these works left by which posterity may form any judgment of their merit, it would unnecessarily occupy space only to enumerate their titles and subjects. It is, however, satisfactory to be able to contemplate some of the marble decorations of the Parthenon, which may without dispute be attributed to the master mind and hand of Phidias. These are the statues and reliefs which were on the exterior of the temple. They consist of single figures and groups which were placed in the pediments, of several of the metopes, and a considerable portion of the frieze of the cella. These celebrated sculptures are without dispute the finest specimens of the art that exist; and they illustrate so fully and so admirably the progress and, it may be said, the consummation of sculpture that it is important their character and peculiar excellence should be well understood by those who desire to make themselves acquainted with the true principles of this art. They exhibit in a remarkable degree all the qualities that really constitute fine art,—truth, beauty, and perfect execution. In the forms, the most perfect, the most

Sculpture. appropriate, and the most graceful have been selected. All that is coarse or vulgar in ordinary nature is omitted, and that only is represented which unites the two essential qualities of truth and beauty. The result of this happy combination is what has been termed ideal beauty. No productions of the earlier schools exhibited this union; Phidias may therefore justly be considered the author of this consummation as we now first see it in the works produced under his immediate direction. The statues of the Ilyssus or river god, of the so-called Theseus, of Neptune, and the large draped groups, are all remarkable for the qualities referred to, united with grandeur of style and simplicity. Wherever the naked form is shown there is the most profound knowledge of its anatomical structure and capabilities of action. The draperies, likewise, are everywhere treated with the greatest skill and with the most careful attention to effect, in their opposition to, and contrast with, the naked. These works deserve also especial notice for the admirable management of composition in relief. The metopes afford the best examples of *alto* or high relief, and the frieze of that which is called *basso* or low relief. In the latter especially, the knowledge and skill exhibited in representing a crowded and busy procession of walking figures, mixed up with riders and horses in every variety of action, and other animals intended for sacrifice, without unseemly and unintelligible confusion, cannot be too highly praised. It may be observed here that the perfect acquaintance which the best sculptors of this time had with the anatomy and character of animals is extraordinary. Myron was celebrated for his accomplishment in this respect, and the horses in the Elgin marbles must be admitted by all competent judges of that animal to be the most perfect representations of shape, action, and high-breeding.

Before entirely quitting the subject of Phidias and his works, an interesting circumstance may be mentioned in connection with the preservation of the two most important productions of the artist,—the statues of Jupiter and Minerva. Pausanias tells us the former was surrounded at its base by a groove or channel of black marble containing oil. The object of this was to supply a sufficient quantity of moisture to preserve the ivory (from shrinking probably), and at the same time to secure the work from the danger of too much humidity, as the Altis was situated on marshy ground. At Athens means were adopted to obviate the damage that might arise from the opposite evil, the Acropolis being in too dry a situation. The statue of the Olympian Jupiter was out of repair soon after its completion. The custody of this work was entrusted to a particular family called Phædruntai. Pausanias says they were descendants of Phidias, and mentions as a remarkable fact that the office was held in the same family in his time.

Among the most celebrated of the scholars and followers of Phidias were Agoracritus of Paros, Alcamenes of Athens, Colotes or Colotas, Pæonius, and others. Of these, the two first appear to have held the highest rank. Agoracritus was the favourite scholar; Alcamenes, judging from the accounts left of him, the most able artist. He is said to have been second only to his master; and one author says, what was wanting in Polyclethus was found in the works of Phidias and Alcamenes.¹ Two works of this artist have been particularly noticed for their excellence: one was a statue of a conqueror in the games, called a "Pentathlus;" the other of a "Venus" of the "gardens."²

The sculptures in high relief known as the Phigalian marbles, and preserved in the British Museum, are also of this date, and deserve attention for the high art qualities they possess. They formed part of the decoration of the

temple of Apollo Epicouros or Epicurius, and were discovered in the year 1812. They represent the contest between the Centaurs and Lapithæ, and the Greeks and Amazons. The various groups in these compositions are remarkably striking for their vigour and expression; and though the forms are rather heavy, they exhibit all the character of a high style of art. There can be little doubt that these sculptures proceeded from the same source as the sculptured decoration of the Parthenon. Pausanias says the temple was built by Ictinus; and as he was assisted by Phidias in his great work at Athens, it is more than probable this sculptor also supplied designs for the Phigalian temple. They bear satisfactory evidence of the influence of the master mind, and their comparative inferiority in some technical points may easily be accounted for by the fact of their execution being left to perhaps inferior artists, working at a distance from the personal superintendence of Phidias.

The perfection of the grand or sublime style of sculpture appears to have had its consummation in the time of Phidias. He executed works of various kinds, but chiefly he was employed on subjects of a high and dignified class, such as were to do honour to the gods, in illustrating the mythology, or in statues of divinities; and the elevated character he gave these performances procured for him the most honourable distinction. It is recorded that he acquired the title of the "sculptor of the gods;" and one writer says, in speaking of the "Jupiter" of this artist, that by the power or excellence of his art he added something to the sublimity of religion.

The next great master who influenced the progress of sculpture introduced a new element into it, which could only have been accepted subsequently to the success which had followed the innovations introduced by the genius and power of Phidias. The latter had boldly freed his art from the prescriptive types and the over-dry manner of the archaic and Æginetan sculptors; but though he had established the fundamental rule that the highest perfection of form is the proper object of imitative art, he still preserved some severity of style in his mode of treatment. Praxiteles of Cnidus is considered to be the head of the school that addressed itself more immediately to the senses. This step had a most important influence upon the art. The object now was not so much to elevate and instruct as to please, and the result was, of course a lower standard of judgment in the people. Praxiteles is spoken of by all the ancient writers as one of the greatest masters who has professed this art. His works in bronze and marble are described as of the highest excellence; and there can be no doubt that they fully merited the encomiums lavished upon them. Still his peculiar merit appears to have consisted not in the imagination or high purpose of his works so much as in the exquisite perfection of his execution. Two of his works in marble are especially noticed for their expression. One represented an aged woman weeping; the other a courtesan, said to be a portrait of Phryne, to whom the sculptor was much attached, and whose features were lighted up with the most joyful expression. Praxiteles executed for the people of Cnidus a naked statue of Venus. This work was considered the masterpiece of the sculptor, and people flocked from all parts to see and admire it. It is recorded, in proof of the value of this work, that the Cnidians were oppressed by a heavy debt they owed to Nicomedes, King of Bithynia, who offered to liberate them from this obligation if they would consent to give up this far-famed statue. The Cnidians refused, however, to purchase their freedom from debt at this cost, and would not part with a work of art the possession of which rendered their city so illustrious.

² Lucian de Imaginibus, Plin. N. H. xxxvi.; Paus., lib. i.

Sculpture.

It has been thought that Praxiteles was the first sculptor who ventured to represent the female form entirely without drapery.¹ It was an innovation somewhat startling, and at first was not generally adopted; but to reconcile, partially, the representation of such forms with feelings of propriety (for sculpture was not yet used merely to gratify indecorous fancy and prurient tastes), a compromise was effected by representing the lower half of the figure draped, as is seen in the fine statues of the "Venus" of Milo in the Louvre, the "Venus" of Capua at Naples, and our own fine statue of Venus or Dione in the Townley collection in the British Museum. It is, however, clear that, from this time, the exhibition of the undraped female figure was a common and popular exercise of the sculptor's art; and perhaps the real decline of sculpture may be said to have commenced when its practice was directed to please the sense or taste for voluptuous forms, instead of addressing the nobler sentiments, as had been done by Phidias and his severer school. The object of this essay being the history of sculpture, and not the biography of sculptors, it is not possible to do more than touch generally upon individual artists, and that only in their character of leaders of schools. Otherwise the fame and extensive practice of Praxiteles would fully warrant a much more extended notice than is here afforded to so great a master.

In the list of eminent sculptors living at this time the name of Scopas claims honourable distinction. He is thought to be the author of the celebrated group of "Niobe and her Children" in the gallery of sculpture at Florence. He also is said to have executed the sculptures on one side of the quadrangular base of the celebrated Mausoleum. There is reason to think that the greater part of the statues composing the Niobe group are but ancient copies from the original work; but even as copies they afford satisfactory evidence of the ability of the artist who conceived the subject, as examples of expression, form, action, and fine style of art. Of the other work alluded to, we may congratulate ourselves on possessing indisputably portions of the original sculptures, though in a mutilated form. They consist of a large collection of objects, as statues, reliefs, fragments of animals and of architectural details, and they certainly may be considered among the most valuable remains that have been recovered from ancient times. They not only illustrate a very celebrated period and school of art, but are undoubted examples of the works of individual sculptors whose names have been handed down to us by the writers of antiquity. They were found on the site of the ancient Halicarnassus, now called Budroum, in Asia Minor; and they formed portions of the famous commemorative monument, of which nothing was known but by tradition, erected by Artemisia to her husband (and brother) Mausolus, King of Caria, who died in the year 353 B.C. It was called the Mausoleum from that circumstance, and has given its name to all subsequent erections of a similar character. It was so remarkable for its scale and the magnificence of its decoration, that it was accounted one of the wonders of the world. Pliny describes this noble monument at great length, and we are enabled from the particulars he supplies to form a very good general idea of its design. The whole composition, formed of marble, stood upon an ample base, of which we have many of the blocks. Upon this was a peristyle of thirty-six columns, of which, and of portions of the architraves, sufficient fragments have reached us to settle a point not mentioned by Pliny—namely, the order of the architecture, which is Ionic. From a centre or *cella* rose a pyramidal structure in steps, and this was surmounted by a marble quadriga. The whole height was 140 feet. The length on two sides, the north and south,

was 63 feet, and on the others somewhat less. Among the sculptured fragments recovered are some of great interest, consisting of statues, portions of colossal horses, and reliefs. Pliny acquaints us that Artemisia employed four of the most celebrated sculptors of antiquity to decorate this monument, and he gives us the names of Bryaxis, Timotheus, Leochares, and Scopas; Vitruvius gives Praxiteles instead of Scopas. These artists executed the reliefs that adorned the sides of the Mausoleum; Bryaxis, according to Pliny, adorning the north face, Timotheus the south, Leochares the west, and Scopas the east. To Pythis was entrusted the execution of the marble quadriga by which the whole was crowned. It is not necessary here to enter into the vexed question which has occupied and still occupies antiquaries and architects upon the precise design of this celebrated work. We have sufficient accounts of its general character and scale, and now most satisfactory evidence in details of the quality of its sculptured decorations. It is this latter particular which gives the work its interest in a history of the art. The school of sculpture which these remains illustrate had reached the highest point of excellence. Founded on the grand and sublime style which characterised the productions of Phidias and his immediate followers, the school of succeeding sculptors whose names we find associated with this splendid erection exhibit a greater refinement and luxury, if it may be so called, of treatment and execution than are found in the previous school. This is clearly exhibited in the manner of working the drapery in the two colossal statues; one of which has been surmised possibly to represent Mausolus himself; the other is a female figure. The drapery about the left mutilated arm of this latter statue, with the effect of the flesh of the limb against it, is an example of consummate art-power. The reliefs represent various subjects, but chiefly contests between men and Amazons. They are full of action and expression, with the greatest variety of composition and most picturesque arrangement: a quality of very difficult and dangerous adjustment in the somewhat severe art of sculpture, but they are here achieved with the most skilful perfection. These reliefs vary a little in width, and indeed in the scale of the figures, showing that there either were different tiers or series of reliefs, or that the different sculptors exercised their own fancy in making their respective decorations of a larger or smaller size. The fragments of some statues of horses show that these works are of a larger scale than any similar works of the kind that have been found in marble. One of them still has some portion of the bronze bridle or head accoutrements remaining. There is one fragment of a horse, in violent rearing action, with a portion of a figure probably reining in the steed. Generally speaking, the horses are of very inferior quality to the rest of the sculpture. All these interesting fragments are now in the British Museum.

The sculptor who may be said to have completed the progressive course of sculpture was Lysippus, a native of Sicyon. He worked chiefly, if not entirely, in bronze. Pliny, Pausanias, and other writers, have recorded a long list of his works, and he is said by the former to have executed as many as six hundred and ten statues. Lysippus was greatly esteemed by Alexander the Great, who allowed him the exclusive privilege of making his statues. He also made one of Hephæstion, the favourite of Alexander, and statues of all the generals who accompanied the prince in his passage over the Granicus. There are some particulars mentioned of the practice of Lysippus which throw light upon the condition of the art at this its culminating point. He is noticed for the care he bestowed on completion and finish, and in working the hair. He also made the heads of his figures smaller than his predecessors (*an-*

¹ Millingen, *Ancient Inedited Monuments of Grecian Art*, No. x., p. 7.

tiqui), and the bodies somewhat more slender, by which the effect of tallness was increased. His works were remarkable for a quality which Pliny describes by the word *symmetria*, and he entirely got rid of a certain squareness observable in the ancient school. A remarkable expression is attributed to Lysippus, which shows how thoroughly this sculptor understood the value of working for effect without sacrifice of truth and correctness of detail. He said, "By the older artists, men were made as they are; by himself, as they appeared to be." It is thought that a bronze statue of Hercules in the British Museum may very possibly be a work of this sculptor. The character of the art of this time had a slight leaning to exaggeration. As the grand, solemn style of Phidias had been followed by a change to the sensuous treatment introduced by Praxiteles, so this latter was succeeded by the effort of a new school to produce additional effect by a more energetic display of action, and somewhat elaborate execution. Lysippus left many scholars who were eminent sculptors; of these, three—Laippos or Daippus, Bedas, and Euthycrates—were his sons. Tisicrates, another, imitated his master so successfully, that it was sometimes doubted whether the work was by Lysippus or the scholar. Chares, the Lindian, the author of the far-famed Colossus of Rhodes, also worked under Lysippus. It is worthy of remark how many celebrated sculptors were natives of Rhodes. Agesander, Polydorus, and Athenodorus, the authors of the group of "Laocoon," as well as Apollonius and Tauriscus the sculptors of the well-known group of "Dirce and her Sons," commonly called the "Toro Farnese," were Rhodians. From this small island, not more than forty miles long and fifteen broad, the Romans, when they conquered it, brought away three thousand statues.

The history of the progress to perfection of Greek sculpture may here be said to be completed. From this time only imitations or varieties of the examples of the three great schools were attempted. The death of Alexander the Great, and the division of the Macedonian empire among his successors was one cause of the decline of art, though some endeavour was made by the Seleucidæ and by Ptolemy to support them in Syria and Egypt; as well as at Pergamus by Attalus and Eumenes. As late as the 145th and 150th Olympiads the names of several sculptors appear; and to this period antiquaries have attributed some celebrated works that have reached our time. Among these, the "Hermaphrodite;" the "Torso" of the Belvidere, bearing the name of Apollonius, the son of Nestor, as its author; the Farnese "Hercules," by Glycon; and of the "Fighting Gladiator," by Agasias, may be mentioned. In the 157th Olympiad (146 B.C.) Corinth was destroyed and sacked by L. Mummius, by whom the finest statues and other works of art were carried to Rome as spoil; and the last blow was given to the hopes and power of the Greeks. Athens, in the midst of political changes, kept up for some time her character for eminence in the fine arts; but after the death of Alexander she began to lose her ascendancy even here. After the termination of the civil war between Pompey and Cæsar, in which Athens had sided with the former, her fate was sealed; though the conqueror treated her with generous consideration, saying, in allusion to her former glory, "He would spare the living for the sake of the dead." Many Greek artists, driven by want from their own country, emigrated to Italy, where they found an asylum and employment among such patrons as Rome afforded; and it is in Rome that the further history of sculpture must now be followed.

In the earlier period of the rise of Rome there was little opportunity or disposition for the cultivation of the fine arts, and though we read of works in sculpture of an early date, they were no doubt the productions of strangers, probably the Etruscans. Mention is made of some equestrian statues in Rome, of Camillus and Mænius, three hundred years be-

fore the Christian era; and in another art, Fabius, a member of a noble family, so distinguished himself as to have acquired the surname of "Pictor." After the capture of Syracuse, Marcellus sent home various works of art from Sicily; and about this time it is supposed Greek artists arrived in Rome. Collections of works of art were made, but this seems to have been done rather from ostentation than from any feeling for or admiration of their merit. Sylla, after the victories he had gained, despoiled Athens, Delphi, Elis, and other great centres of art, and had the treasures carried to Rome, till at last collecting statues became a fashion. Verres is well known for the avidity and injustice with which he indulged the passion for acquiring such works during his government of Sicily. Many names of sculptors of this time have been recorded, but all appear to be Greeks,—Pasiteles, Arce-silas, Strongylion (the author of the statue of the Amazon called "Eucnemis," from the beauty of her legs), Olympios-thenes, and others. Julius Cæsar appears to have had a taste for art, for he not only collected largely in statues, gems, &c., but he also embellished with fine public works Rome and many cities of Gaul, Spain, and other countries which owned the rule of Italy. The same may be recorded of Augustus, who not only decorated the city with works of art, but had statues erected in honour of eminent men. In this age the name of Agrippa stands pre-eminent for his public spirit and princely liberality in erecting useful and ornamental edifices in and about Rome. The Pantheon, which still remains to do honour to this munificent patron of art, was erected at the charge of Agrippa, who, it is recorded, employed Diogenes the Athenian to enrich it with sculpture, all of which seems to have perished. The celebrated statue of Germanicus in the Louvre is no doubt of this period. Vitruvius the architect, Dioscorides, Agathopus, Epitynchanus, and others, gem engravers, were also practising with honour at this time. Some of the best-known productions of sculpture have been attributed, with more or less reason, to this age, but the discussion of their date would scarcely come within the objects of this general history.

The reigns of Trajan, of Hadrian, and the Antonines may be considered the best age of sculpture in Rome, though there is no reason to believe the arts were practised even then by natives. Hadrian, there can be no doubt, had a real love of art. He completed the temple of the Olympian Jupiter at Athens, which had been left unfinished for ages. In Italy, the remains of his celebrated villa near Tivoli prove the scale of his magnificence; while the high quality of the statues, reliefs, and other objects that have been found there, establish the claim of this emperor to rank not only as a liberal and munificent, but as an enlightened patron of art. Of this time are the fine statues of Antinous.

Here and there, after this date, an occasional revival of art occurred, but the general tendency was to its rapid decline, till Constantine endeavoured to give a new impulse to its practice. But this failed to produce original works of merit, and the emperor was driven to decorate his new seat of government at Byzantium with ancient statues and works of art that could be procured from other places. Many most important productions in sculpture, in marble and bronze, were here accumulated when, in 479, a fire destroyed the greater part of them. Constans, who was Emperor of the East, in 661 was driven from his capital, and fled to Rome. He despoiled it of all the works he could seize, and had them sent to Sicily, where he found an asylum and where he died. The arts in Rome were now hastening to their final extinction, and all the well-intended efforts of Charlemagne, and afterwards of Theodoric, were insufficient to save the finest remains of antiquity from the ravages of their barbarian followers. The Empire of the West was at an end, and the Roman name was only known

Sculpture. at Constantinople, where, however, some of the finest productions of ancient sculpture were still preserved. When Baldwin made himself master of Constantinople further misfortune befel the arts. All the metal statues that could be seized were melted down and converted into money. Amongst these, it is painful to know, was a magnificent statue of Juno by Lysippus, a colossal "Hercules," a statue of Helen, and many other productions of the best period of Greek sculpture.

The monuments of the Romans are very numerous, and occasionally some fine portraits are found among them. They also have been very useful in illustrating the history and habits of the nation. But Roman sculpture is in all respects essentially inferior when compared with the productions of the Greeks. With one people it was the expression of original feeling, in forms of the most perfect beauty, the consummation of the utmost refinement of sentiment and intelligence: with the other the best of it was only imitation. The result was for the most part insipidity and tameness, even when the mechanical imitation was tolerably successful.

The decline of sculpture, after the few fitful attempts to restore it by some of the later rulers of the dismembered and decaying Roman empire, was rapidly progressive, till at last it is impossible to connect the miserable performances of the artists of these times with the fine ancient examples, which were still abundant and might have served as valuable guides had any sympathy with their excellence existed. But there was no general interest felt in the subject, and the efforts to revive it, emanating as they did from a few individuals, had little or no success.

Italy may justly claim the honour of the new birth of art. It has been said that the monks of the early Greek and Latin churches kept alive its dying embers by illuminating manuscripts and church services, and by decorating the chapels of their convents with rude paintings; but it is scarcely possible to admit this, and to consider the awkward and ignorant attempts at design of this time as an effect or continuation of any art, deserving the name, that had preceded it. Modern art must be estimated by a totally different standard, and, thus considered, the circumstances of its rise and development give it an interest and importance which it never could claim if it were only a spurious imitation of the debased and exhausted art of the ancient schools. There are, besides, some curious circumstances that arrest attention at this point in the history of art. One of these is the fact of its almost total extinction among that remarkable people, the Greeks, by whom it had been carried to its highest perfection; and its revival in a country where, in ancient times, its existence had been ignored, its practice looked upon with a feeling akin to contempt, and where collections of works of art, when made at all, were formed much more frequently from ostentation than from any real interest that was felt in them. The next fact to be noticed is, that when the early Christian communities desired to call in the aid of art to enforce or illustrate the new faith, the employment of beautiful forms in representing the Saviour and other sacred persons was strenuously opposed by the fathers of the Eastern Church; while the Western Christians contended, on the other hand, that no form could be too perfect for this object. This curious and, as it affected art, important controversy was carried on with the greatest warmth on both sides; but finally the cause of the beautiful was established in the West, and resulted in that happy development which in the course of years so eminently distinguished the schools of Italy. In the East, formerly the home of all that was beautiful in art, but now, where beauty, as a means of illustrating divine and Scripture subjects, was proscribed; the reverse has taken place. The religious paintings of the Greek Church are of the most debased and barbarous quality; and all classes of fine art

among this people seem to have sunk into utter insignificance. **Sculpture.**

The revival in Italy has usually been dated at about the tenth century; probably because at that time, or a little later, a resemblance is supposed to be traceable to some of the old types, by which a connection would appear to be established between the later and earlier practice. But the real beginning of modern art may be reckoned from an earlier period. Flaxman thought it might be dated as far back as seven centuries earlier, when Christianity had, under Constantine, become the religion of the empire. It is true that the early Christians adapted, and even adopted, pagan designs, to ornament, if it can be so called, their subterranean hiding-places with illustrations of Scripture subjects, or with allegorical emblems; but it is curious to find that an entirely original style of art was all the while growing, whose character bore no resemblance to what already existed, and which might so easily have served for examples to the sculptors and painters of this dark period. This fact offers grounds for some speculations of interest, with reference to the origin of a distinct and original school of design, which should fulfil the same office to the new religion which the art of its time had done for the older and now obsolete systems; but it is not expedient to enter into the discussion of this subject in a compressed history of sculpture. It may, however, be remarked that the mind and spirit that are observable in the paintings and sculpture of the class referred to display a feeling that justly claims for them the merit of originality, and shows their entire independence, in that respect, of the ancient schools. This freedom of thought is particularly striking in the compositions of the early Christian artists of subjects that would seem naturally to tempt them to recur to the mode of treatment of their predecessors in art,—namely, those in which allegorical figures and symbols were required. Many instances of this originality might be adduced, but it will be sufficient for the purpose to refer to the works of one of the earliest and most remarkable painters, Giotto di Bondone, in the "Salone" at Padua, and in the "Capella dell' Annunziata" in the same city, in proof of the fact stated. Early Christian art was as distinctly divided from the art of the Greek schools as the religion itself which gave it birth was, in its earlier and pure teaching, distinct from the numerous systems that had before filled the world; and it is important to show its claim to originality, as it will assist the student of the history of art in understanding many of the causes of the fluctuations and changes that have characterised all the modern schools of sculpture. A depth of thought, and an earnest, solemn character pervade the art of the Christian designers, which shows they draw their inspiration, not second-hand from models, but from their own inward feelings. At first, indeed, their attempts in art were painfully rude, compared with the wonders of the Greek schools. But it must be borne in mind that the purpose of Christian art never was the same as that of much of the sculpture of the Greek schools,—namely, the representation of beautiful form for its own sake. After the first attempts at design, usually in single figures,—gaunt and staring images of apostles and saints, or, if in numerous figures, without any knowledge of composition,—the religious artists seem to have aimed at appealing to the sympathies, or at awakening reflection, rather than of gratifying the sense by presenting to the spectator such objects as should be only pleasing to the eye or the fancy. Art was not required as a mere appendage to luxury. Its recommendation in this respect had long ceased to exist, and the sensuous schools of the post-Phidian period had, as has been shown, in some degree, helped to lower its character even among the ancients, after its higher religious and heroic object had been lost sight of. Among the moderns it had

Sculpture an entirely new mission. Exercising art on this principle, the artists of this age may therefore consistently be considered men of original genius. Instead of merely copying, they drew from their own innate and independent sources of sentiment, and the result was, that the art they produced gave the promise that had been realized in Greek art of the fifth century B.C., when it was directed by the master-spirits of that age—of deep expression, beauty, and refined taste. The causes that tended to check this consummation will be considered hereafter.

The first artist whose works arrest attention for the real art-feeling they exhibit is Niccolò Pisano. He appeared early in the thirteenth century, and, as his name implies, he was a native of Pisa. It was usual in those days for the same artist to practise in all the three branches of the arts, painting, sculpture, and architecture; and many examples still exist of this combination. In the hands of Niccolò and his son Giovanni of Pisa, however, sculpture had its own distinct and important character from the exclusive devotion given to it by these sculptors; and their employment in the decoration of the sacred edifices that were being erected in all parts of Italy enabled them to carry their art to a high degree of comparative excellence. The cathedrals of Pisa, Pistoja, and Orvieto especially are rich in their works. In order to account for the superiority of these artists, it has been supposed that they derived considerable advantage from the opportunity they had of studying some remains of ancient sculpture which were preserved in the Campo Santo of Pisa. It is highly probable that they may have been impressed with the technical superiority of these ancient sculptures; but that their own original character of design or of sentiment, the latter especially religious and Christian, was in any way affected by anything they saw in these works is by no means apparent; and it is not till much later, when art was much more universally practised, that the influence of such examples can be traced. A reference to some few of the productions of the two great sculptors of the school of Pisa will illustrate the view here taken. The rilievi, in marble, which enrich the front of the cathedral of Orvieto especially merit attention. The subjects are taken from the Bible, and represent the Creation of Adam and Eve, the Temptation, the expulsion from Paradise, and others of the kind. These designs exhibit very rare qualities of beauty and expression, and are remarkable indications of the deep art-feeling which has made the Pisan school so celebrated. They of course show the want of practice in the more mechanical requirements of art and in freedom of execution, but the higher qualities that abound in them amply compensate for these merely technical shortcomings. Simplicity, grace, and feeling are all combined in these striking compositions; and in the figures of angels especially there is an exalted and pure character that is at once impressive and elevating. The draperies are also treated with great taste and skill. Cicognara (*Storia della Scultura*) thinks that these are the productions of some scholars of Niccolò, and not by that sculptor, but the question does not affect the great merit of the works. A semicircular bassorilievo by Niccolò, representing the "Taking down from the Cross," placed over a door in the front of the cathedral of Lucca, is also a composition of great merit, both for its design in an artistical point of view, and for the exquisite feeling shown in it. Another remarkable work by the same author may be seen at Siena, in a rilievo representing the Last Judgment and the final punishment of the wicked. Judging from the general character of the works attributed to Niccolò, the subject could scarcely have been congenial to the spirit of the artist. His special ability was in treating gentle, and touching, and delicate subjects. This composition has, however, considerable merit, in the bold treatment of the terrible scene; the crowding together

and shrinking of the guilty, and for the skill occasionally shown in the arrangement of the different groups. There are two figures of angels introduced to which the sculptor has been able to give all that grace and beauty so observable in his other works. Niccolò lived to an advanced age, and left many distinguished scholars and imitators, of whom his son Giovanni of Pisa, Arnolfo of Florence, Margaritone of Arezzo, and Guido of Como, gained well-deserved reputation.

In 1330 Andrea, the son of Ugolino of Pisa, who was settled in Florence, executed one of the bronze gates of the baptistery in that city. It is a work of great excellence for its date, though it is deficient in some practical points. He also executed some statues in marble, but they are inferior to many of his productions. A sculptor of great merit, Andrea Orcagna, was contemporary with Andrea Pisano, and executed various works in Florence. Some of these are preserved in the small chapel or oratory, called Or San Michele, in that city, and justify the praise that has been accorded to this artist by all competent judges. He was not only a sculptor, but was distinguished also as a painter, an architect, and a poet. His style of art partook of the dry and minute character of the early school, but he was superior to his contemporaries in his treatment of drapery. Among the sculptors who highly distinguished themselves at this period, towards the end of the fourteenth century, Luca della Robbia claims honourable mention. His subjects are all of a serious or religious character, and among his productions are some of great beauty. He chiefly delighted in representing groups, in high relief, of the Virgin and infant Christ, or the Saviour and St John as children, and similar subjects. There are two works of Luca preserved in the sculpture gallery in Florence which deserve particular notice; they are bassi rilievi in marble, representing a choir, or a group of church singers. They claim attention for their skilful composition, and for the truth of the expression of the different figures. Indeed, they only require elevation of form to place them on a level with the best productions in the art. Luca della Robbia is well known in the history of sculpture as the inventor of a peculiar mode of working in *terra-cotta*, the material of which almost all his groups are made. He painted his compositions, and covered them with a beautiful and peculiar varnish of which he made a great mystery. It is said he never disclosed it to any one, but committed the process to writing, and inclosed it in one of his clay models before baking it. Whether this was the case, can only some day be known by the accidental destruction of that one of his works which is the depository of the secret. Luca died in 1442. In Florence are preserved some very interesting compositions in rilievo, in marble, by other sculptors of this period, among whom Benedetto da Rovezzano may be particularly mentioned. In these works an approach is seen to those qualities which constitute real art progress. There is not only occasionally very agreeable form, but considerable skill and feeling in the treatment of drapery.

A crowd of artists now appear in all parts of Italy, employed in erecting and decorating the churches which the piety and liberality of the age were dedicating to religious service, and in honour of particular saints. Only the more celebrated can be selected for notice from this long list; but it would be unjust to the striking superiority of two of these to omit to record especially the names of Lorenzo Ghiberti and Donato di Betto Bardi, better known as Donatello. The great work of the former of these sculptors is too well known to require an extended notice in this place. It is the beautiful composition of rilievi in the panels of one of the bronze gates of the Baptistery at Florence. Several sculptors had been employed on parts of this edifice, but the contribution of Lorenzo Ghiberti so far surpasses them all that Michel Angelo is said to have declared, in his admi-

Sculpture

Sculpture. ration of them, "they were worthy to be the gates of Paradise." The subjects are from the Old Testament. They display a fine feeling for composition, a superior acquaintance with the beauty and movements of the human figure, refined expression, considerable skill in execution, and are in all respects of a higher quality of art than any contemporary productions of the kind. Unfortunately, in the treatment of these otherwise admirable compositions a great principle of art has been infringed by the attempt to represent perspective appearances by different degrees of relief; effects which can only be truly and correctly produced by the aid of colour in the atmosphere, and by the skilful artificial distribution of light and shadow, as in a picture. Modern sculptors have constantly erred in their attempts to meet this difficulty, inherent in their art. The great masters of ancient sculpture have shown us in their works that they could carry the art to its highest perfection within its own legitimate limits, and in rilievo of all kinds they confined the representation to one plane. The gates of Ghiberti are injured by this seeking for picturesque effects; and the number of small parts, the variety of unimportant objects, as trees, animals, &c., deprive it of that breadth which is so valuable a quality in sculpture. Ghiberti was less successful in some bronze statues than in his compositions for the baptistery. Of a statue of St Matthew, Flaxman says: "It wants the severe chastity of the apostolic character, and the head is inferior to those in the spandrels of his gates; the attitude also is affected, and the drapery unnatural."

Donatello was a Florentine, born in 1383. The works of this sculptor were highly prized, and he was extensively employed. Many of his productions are still remaining in various cities of Italy. Two statues of St George and St Mark, which have obtained well-deserved celebrity, are in the oratory before mentioned, of Or San Michele at Florence. The former of these is remarkable for its simple action and calm, grand expression, reminding the spectator of the vigorous and nervous manner which characterised the works of the immediately succeeding school. The statue of St Mark received the high compliment of Michel Angelo's admiration when he exclaimed, with reference to its truth to nature, "*Marco, perchè non mi parli.*" In Florence also are some very interesting and, allowing for the imperfect state of art of the time, curious bassi-rilievi in marble by this sculptor. They represent groups of children dancing: the background of these is very curiously treated, being closely covered with small round pieces of gold-leaf, like coins. Some rilievi of very great merit by Donatello are also to be seen at Padua. Compared with the works of his immediate predecessors, there appears sometimes a degree of exaggeration in the style of this sculptor; in the bending of the joints, and the smaller articulations of his figures. This may have arisen from his desire to avoid the dry or timid treatment of the earlier schools, and so far may be considered a proof of the forward movement of art. The productions of the two sculptors above named are interesting subjects of examination to all who take an interest in the development of a really original school of sculpture. Donatello lived to a great age, and left many scholars. One of these was Giovanni di Pisa, the author of a basso-rilievo of no ordinary merit in a small chapel of the church of the Eremitani in Padua. It represents the Madonna and infant Christ, with three figures of saints on each side. Passing over names of less celebrity, though meriting notice in a regular history of sculpture, that of Andrea Verrochio claims distinction as the master of Leonardo da Vinci, and of Pietro Perugino the master of Raffaello. Verrochio at first was a painter, but it is said he grew jealous of the performance of Leonardo in a work in which the scholar was assisting the master, and relinquished that art for sculpture. There are several works by him, statues and rilievi, at Florence. Rustici, who studied

also under Verrochio, was a sculptor of merit. He was invited into France by Francis I. Amongst his works we find many of classical subjects. He died in 1550.

The general character of art had up to this time been essentially of a religious kind. The deficiency in the modern Christian school of sculpture was in the technical requirements of the art; but these seemed to be attainable before long, judging from the rapid strides that painting and sculpture were now making. In the expression of deep sentiment, in simplicity, in chaste beauty of form in sacred or holy subjects, in the arrangement and quality of draperies, and the harmonious flow of lines, no school of art of any time or nation can show works of greater promise than may be found in the productions of the mediæval artists.

This hopeful condition of sculpture, upon which might have been founded the expectation of the art reaching a high state of excellence (as ancient sculpture had done under similar influences), was destined to be interrupted.

At the period which our history has reached the discovery of the long-lost treasures of the classical writers of antiquity gave an extraordinary impulse to the studies of the lovers of literature. The Medici, the accomplished rulers of Florence, liberally encouraged men of learning, and Florence became the centre of the revival of Greek and Roman letters. The fine arts, always so dependent in modern practice upon the influence of those in high position, were soon made to feel the effects of the new movement. The sentiment for religious and Christian art was superseded by the admiration of everything that had the authority of the ancients; in conformity with the new taste, classical and heathen subjects were now the fashion in sculpture, and these, as well as all others, were to be treated after the ancient examples. Even where works of a religious character were required, the ancient mythology was incongruously and absurdly mixed up with subjects of the Christian faith, producing the most offensive contrasts, and, of course, entirely destroying the proper effect and intention of art. This passion was not confined to one state of Italy. The Popes, two of whom were members of the House of Medici, equally patronized the revival of classical tastes; and Rome rivalled Florence in its anxiety to re-establish the style and feeling of the great Greek and Roman periods in their literature, their art, their philosophy, and, if history is to be trusted, even their morals. Its influence upon the style of the literature of the day is remarkable, as it led to the employment of the dead languages in the writings and correspondence of learned men instead of their native tongue, which for a time was ignored and proscribed as vulgar and unworthy the use or attention of real scholars. That these should appreciate the refinement and excellence of the writings of the sages and poets of antiquity, and that those competent to judge art should at once acknowledge the superior objective beauty of Greek sculpture cannot be a matter of surprise; but there can be no doubt that the immediate effect upon art of this excitement was to check its development in a right direction, as a means of addressing modern sympathies. Classical subjects were sought for, because in these a closer imitation could be made of the classical mode of representation, and the conventional treatment of the ancient schools, exhibiting nude forms, was introduced, however incongruous its application, to gratify this dilettante taste. The study of the ancient examples was capable of effecting, and no doubt did effect, very great changes and improvements in the technical parts of sculpture, but it cannot be denied that it also brought with it certain disadvantages. The pure, simple, and expressive character which was so remarkable and so valuable in the rising school of religious designers, succumbed to the powerful influence of the pseudo-classical taste; and, as the motive

Sculpture. that now impelled the artists was factitious, the sculpture they produced was unreal in its sentiment and unimpressive in its character.

However indisputable the charm of beautiful forms in the abstract, their true appreciation must be a consequence of study and reflection; and therefore, unless they are employed in the expression of intelligible ideas, the community to whom art should address itself cannot derive any adequate advantage from their display. It is the *sentiment* of art that first attracts and fixes the attention of intelligent people long before the *form* in which it is presented becomes the subject of critical examination: a fact constantly proved by the fascinating power of some of the productions of the earlier Christian designers, which are pregnant with meaning, but in which the technical recommendations of the schools are often entirely wanting. These observations are by no means irrelevant or without their use in the history of sculpture. They assist in accounting for the entire change that is now seen in the "motive" of the art of the age; and especially in this art, which seems so prone to ally itself with the older associations, from the greater opportunity offered by classical subjects for the tempting display of naked forms, muscular development, and other mere academical qualities.

The fifteenth, and the early part of the sixteenth centuries, comprehend a period of great interest in the history of literature and the fine arts; and although some disadvantages accrued from the first violent reaction that took place upon the introduction of classical tastes, it would be unjust to the memory of the noble patrons of learning in those days not to record their title to the gratitude of posterity for the generous protection they extended to scholars and artists of eminence. The extraordinary talents of the House of Medici had raised that family to the highest honours in their native Florence, and their influence was powerfully exercised far beyond the limits of their own country. Lorenzo, who had by his princely habits and liberality acquired the surname of "il Magnifico," added to the lustre of his position by attaching to his court the most distinguished literary men of all nations. Rome was also at this time governed by pontiffs who equally sympathized with the liberal tastes of the Florentine Medici. Julius II., who was elected to the tiara in 1503, gave the utmost encouragement to the great artists of his age, and Leo X., who succeeded him, was equally liberal, making Rome a centre of attraction for all that was classical and epicurean. Leo was a member of the family of Medici. He was soon after succeeded by another scion of that remarkable family, Clement VII., for the intermediate Pope, Adrian VI., occupied the throne scarcely a year; and he also continued to encourage the arts with the same liberality that had distinguished his predecessors. A few names of sculptors who lived at this time will show the character and amount of artistic power that was called into action by the generous and enlightened protection given to these pursuits by the sovereigns of this age. Michel Angelo, Torregiano, Bandinelli, the Ammanati, Rustici, Montelupi, Sansovino, Benvenuto Cellini, Francavilla (and others might easily be added to these), are amongst those who have left works which have honourably illustrated their age and country.

The works of Michel Angelo Buonarroti, who was born in 1474, afford excellent examples of the condition of sculpture at this period. They indicate unmistakably the influence of the new opinions that were gaining ground, marking most distinctly the transition from the original and unsophisticated feeling that had been the motive of the earlier Christian artists to the artificial stimulus given by the recovery of the marvels of classical sculpture. This, the greatest artist of modern times, has left productions of mind and hand as striking for the inventive power displayed in

them as for their wonderful execution. They show there **Sculpture.** was no deficiency of ability when such works as these appeared. Michel Angelo, personally favoured by Lorenzo de Medici, studied in the school established by that munificent patron of the arts, and no doubt there acquired both a feeling for fine form and something of the classical taste which was likely to be engendered by association with enthusiastic scholars, and by the constant contemplation of fine remains of antiquity. Many of his works exhibit this influence, but, as will be seen, not to the extent of destroying his own grand and peculiarly original character of design. Among those of his productions which may be adduced in support of this opinion may be especially noticed the fine and touching group called "La Pietà" in St Peter's at Rome, representing the Virgin supporting the dead body of Christ; a performance exhibiting much of the peculiar mannerism of the artist, but possessing also the highest claim to our admiration. The statue of Moses, forming a part of the decoration of the unfinished monument of Julius II. at Rome, and those of Lorenzo and Giuliano dei Medici, at Florence, may also be referred to in illustration both of the originality and the power of this grand mediæval sculptor. These indeed are works which may challenge comparison with the best remains of ancient art for sentiment, breadth and grandeur of treatment, composition, and intimate knowledge of form, while at the same time they are totally distinct from the antique in the originality of their conception. The statue of Moses, though by no means free from the fault of exaggeration so justly objected to in the works of M. Angelo, is one of the grandest efforts of genius, and truly illustrates the forcible expression applied to the character of the artist's style,—"*Di Michel Agnolo la terribil via.*" The other statue presents Lorenzo seated, absorbed in thought, leaning on his hand. Here again there is no real resemblance to the antique, but it rivals the best excellences of the ancients in expression, with repose and dignity. It is impossible to look at this fine work without being forcibly impressed by the *mind* that pervades it. In the same chapel are other remarkable works of this artist. They are allegorical figures meant to represent Day and Night, the Dawn or Early Morning, and Evening, and they form the accessorial decoration of tombs of the Medici. They bear the impress of the master mind and hand; but it has been very properly objected to these works that their meaning and object is far from clear, and that their exaggerated action and treatment are not in character with the requirements of monumental design. In the chapel referred to there is also an unfinished group of "Charity," of fine design and execution. A masterly alto-rilievo in marble of the Virgin, with the Saviour and St John as children, at Florence, and another of the same subject, differently treated and very unfinished, in the library of the Royal Academy of Arts in London, deserve honourable mention as examples of M. Angelo's genius in another class of sculpture. Another well-known work by M. Angelo is in the church of La Minerva in Rome. It is a statue of our Saviour, standing, and holding the Cross. The figure is life-size, and is in the revived classical or academical style, muscular and almost entirely nude. It is, however, little more than a careful and successful study of the naked model, and is deficient in appropriate character and fitness, both as regards the subject and its position. The intimate knowledge of anatomy and acquaintance with the human form, possessed by Michel Angelo beyond all the artists of his time, allowed him to indulge in the utmost freedom in giving expression to the suggestions of his energetic and daring imagination; and this mastery over the technical difficulties of his art appears sometimes to have tempted him to indulge in its display at the expense of that sobriety and simplicity which are such valuable qualities in sculpture,

Sculpture. and whose presence is so remarkable an element in all the finest examples that have come down to us of the Grecian schools. It would carry us far beyond our limits if we were to attempt to give a complete review of the works of this great artist. The influence he has exercised would indeed justify a much more extended notice of himself personally, and of his productions, but in this place it must suffice to refer to these as subjects well deserving the careful attention of the student. Although M. Angelo has here been considered as a sculptor only, he has also left noble works in the sister arts of painting and architecture. Among the former, the well-known compositions in the Sistine Chapel at Rome, illustrating the grand scheme of Scripture revelation, from the Creation to the Final Judgment, are unrivalled in invention, profound thought, knowledge, and grand style of design. These truly sublime performances, whether taken alone or in connection with the other proofs of the power and vast range of his genius, place their author far above comparison with any known artist, ancient or modern. Nor was it in the fine arts of design alone that the great ability of M. Angelo was conspicuous. The political circumstances of his country called forth his talents in other service exercises, and it was in strengthening the defences of Florence that he added to his well-deserved reputation as an artist also that of one of the most accomplished masters in military engineering and fortification. The few remains that have reached us of his literary works, in his letters and sonnets, exhibit him likewise as an elegant writer and poet.

Pietro Torregiano was a distinguished sculptor of this time, the contemporary and rival, in some respects, of Michel Angelo; of whom his jealousy was so great that on one occasion, in a fit of passion, he struck him with a sculptor's hammer and broke his nose. The disfigurement caused by this outrage is seen in all the portraits we have of the great Florentine artist. Torregiano was invited to England, and was employed upon the tomb of Henry VII. in Westminster Abbey, a work of great interest and a sufficient proof of this artist's ability. In the Rolls chapel is a statue by Torregiano which deserves notice. It is in *terra-cotta*, life-size, and painted. It represents a judge, and is remarkable for its truth to nature. Torregiano afterwards went to Spain where he died. Sansovino and Baccio Bandinelli deserve particular mention for their valuable contributions to the art of this age. They have left behind them works of great merit, in proof both of the great ability of the respective artists, and of the extensive employment of sculpture in Italy during this time. Many of Sansovino's performances are at Venice; Bandinelli appears to have worked chiefly at Florence. Many of the productions of this period claim our admiration for great qualities of art, but it must also be added that all are more or less imitations. It is seldom that any really original ideas occur, the sentiment as well as the character of treatment being more or less borrowed from the "antique."

Among the prominent artists of the time Benvenuto Cellini claims a distinguished place. He was a sculptor of great power, though his works, partaking of the character of the age, are marked by some exaggeration of action and an unnecessary and injudicious display of academical study and anatomical knowledge. He executed some large statues; and his figure of Perseus especially, in the Loggia del Gran Duca at Florence, notwithstanding it has great faults, is a production of great merit. B. Cellini is chiefly celebrated for his smaller works in metal (gold, silver, and bronze) and precious stones. Some of these, consisting of richly-ornamented cups, salvers, shields, sword-handles, and similar objects, are of great excellence, and show the undeniable skill and taste of the artist in this branch of his profession. Cellini wrote on his art, describing his practice and experiments in the then known processes of metal-founding.

He also published his autobiography, one of the most curious and amusing works illustrating the manners of the sixteenth century that have come down to us.

Guglielmo della Porta executed, among other works, the monument of Paul III. in St Peter's at Rome. Two statues in this composition, representing Pudence and Justice, establish this sculptor's claim to high consideration. They are not in harmony with the requirements of a Christian monument, nor are they fit productions to be placed in a church; but as works of art they merit the high praise that has been accorded them. This sculptor was the friend of Michel Angelo; and his sculpture, especially in the figures referred to, shows the influence exercised on art by the great master. The latter statue has been partially draped since Della Porta's time.

The quality for which the sculptors of the end of the sixteenth and the seventeenth centuries are chiefly remarkable is a love of display in the executive parts of their art. This led to a serious evil, and to the decline of art. The object with them was not to improve the public taste, or to elevate and improve the minds of the people, but to astonish the spectator by their bold and skilful ingenuity. The three sculptors who were most distinguished for their merit and for their faults in this respect are Giovanni de Bologna, Bernini, and Roubillac. These artists were essentially men of genius, and, though their disregard of the true principles upon which only sculpture can be successfully practised must be deplored, it would be most unjust to withhold from them the praise to which they are entitled for such merit as they undeniably possessed. The group in marble called the "Rape of the Sabines" at Florence, and the bronze statue of Mercury in the gallery also at Florence, place Giovanni de Bologna, in spite of the defects referred to, in the highest rank of sculptors. They deserve commendation for some of the most valuable art qualities,—expression, invention, skilful composition, a knowledge of form, and great execution. The Mercury is full of energy, and is conceived in the true spirit of poetry; but, though classical in their subjects, they are far removed in their treatment from the purity and the charming simplicity which are so essentially a part of classical design. They offend from the extravagance of the action and the twisted contortions in the former group, and from the want of refinement in the forms appropriate to the messenger of the gods, in the latter statue.

Bernini was a Neapolitan, and was born in 1598. His imagination was fertile, and his power of execution of the first class. Unfortunately, this power was uncontrolled by submission to the necessary principles of his art. Bernini delighted in the most curious and daring experiments upon his materials, and treated marble as if it had been clay or wax. Under him all the distinctive bounds of sculpture were transgressed, and the object seemed to be to rival the painter's art. Clouds, landscape, perspective, and other unattainable representations were attempted, till the whole subject is confused in the flutter of unintelligible details. That he was an artist of unquestionable genius cannot be denied, but no one probably did more to precipitate the fall of sculpture than Bernini. The immense patronage he received during a long career (for he lived during nine pontificates) filled Italy with his productions. Among the most remarkable may be noticed his group of "Apollo and Daphne," for its bold invention, the forcible manner in which the story is told, and the "bravura" of its execution. The god is pursuing the unwilling fair one, and at the moment of his reaching her she is, in answer to her prayer for protection, changed into a tree. The passion of the lover is displayed in his eager action and his flying hair and drapery, while the metamorphosis of Daphne is shown by her floating tresses, her fingers' ends and her toes sprouting forth in elaborately-executed laurel leaves. The bad taste

Sculpture.

of this picturesque treatment is only equalled by the extraordinary executive talent displayed in the representation. The "Extacy of Sta. Teresa" is another work of the kind, in which, amidst the flutter of drapery and clouds, it is difficult to discover the figure of the saint. In St Peter's the magnificent monuments of Urban VIII. and Alexander VII. are examples of the merits and defects of this sculptor; marvellous for their execution, but debased by the most meretricious taste. The colossal statues of the Four Doctors of the Church, in bronze gilt, supporting the chair of St Peter, are also by this artist. The idea is grand, but the attitudes are affected and the forms exaggerated. In his statue of "David preparing to hurl the stone at Goliath"—a work of great energy and expression, and executed when he was young—Bernini is said to give a portrait of himself. The fountain in the Piazza Navona at Rome is another of the numerous strange and daring performances of this artist.

Allessandro Algardi, of Bologna, was contemporary with Bernini, and deserves mention, although his works are injured by the same defects that characterise the productions of that sculptor. Algardi's great and best known performance is over one of the altars in St Peter's at Rome, and represents St Paul and St Peter appearing to Attila and his hosts. It is in marble, in rilievo, and measures about 30 feet in height by 15 in width. There are passages of considerable merit in this composition; but unfortunately it is all through treated upon the principle of a picture, and attempts effects which can only be properly rendered by colour. The numerous figures and reliefs of *putti*, or children, by Francisco di Quesnoy, better known as "il Fiamingo," have given this sculptor a well-merited title to distinction; and a statue by him of Susanna in the church of La Madonna di Loreto at Rome may also be noticed as a work of great feeling and even beauty.

Roubiliac followed in the same road, and his great ability increased his influence in establishing a most meretricious school of artists. The fact of his having had great employment in England enables us to judge more easily of the merits and demerits of his style. One of his best works is the statue of Eloquence, in the monument of a Duke of Argyle in Westminster Abbey. The action is earnest, and the expression full of character. In the same church is a much-commended work in memory of Lady Nightingale. It shows, like all the productions of this artist, great power; but it is an example of mistaken design, and shows how fatally the transgression of the true rules of art must act. A much-admired work by Roubiliac is the monument of Bishop Hough in Worcester cathedral. In the hall of the British Museum there is a statue by him of Shakespeare. Roubiliac has shown marvellous ingenuity in his execution; but he has done himself injustice by bestowing so much pains upon the inferior accessories of flying draperies, fringes, the minute details of dress, in buttons and button-holes, perukes, and the fine folds and clocks of stockings, which withdraw the attention from many very admirable qualities in the nobler parts of his designs.

It is not necessary to dwell longer on this phase of sculpture, and no advantage can be gained by enumerating the minute and laborious performances of the smaller race of sculptors who imitated the worst peculiarities of the school. In the church of S. Severo at Naples are some very curious examples of patience and bad taste in statues by San Martino and Corradino; one is of Modesty, covered all over with a thin veil, another a figure of Falsehood within a net of which the meshes are relieved, and a third represents a dead Christ covered with drapery. Others of the same kind might be mentioned; but it will be seen by what has been said that sculpture no longer held a position of dignity, nor was it practised in a way to receive or deserve the admiration of true judges of art. The above pieces of workmanship are specimens only of the carver's skill and

patience; and such sculpture, instead of being looked upon as fine art, can rank but little higher than an exercise of mechanical ingenuity; for it often is totally independent of invention or sentiment, or other really artistical quality. Occasionally an artist of superior taste or higher feeling in art appeared, but he was not seconded or supported by any refinement in his patrons, nor by the sympathy of the public. The talent that existed—and the names of the sculptors above mentioned prove its existence—was exhausted in the endeavour to excite curiosity and admiration for the skill shown in pretty conceits or elaborate execution. The magnificent collections of ancient sculpture preserved in the cities of Italy, at Rome, Florence, and Naples, failed to impress upon sculptors or patrons the value of those principles which had led to the perfection of Greek art; and even when their forms, modified by the fashions and bad taste of the age, were repeated, there was no true feeling or inspiration to elevate the works above the character of indifferent copies or tame imitations.

The honour of giving a new direction to taste, or rather of leading it back to a recognition of true principles, is eminently due to two sculptors of our own age, Canova and Flaxman. To the former Italy owes her emancipation from those false perceptions which had, from the influence of the Bernini school, so long diverted the current of pure taste. To Flaxman the art owes equal obligation, though he had not the same opportunity as Canova of making his superior merit known. No modern sculptor has entered so deeply into the recesses of ancient art as Flaxman; his style was founded upon their principles, combined with the simplicity of the Pisani and others of the fourteenth century. The purer and simpler taste of which some of the earlier works of Canova, as his "Theseus," "Dædalus," and "Icarus," and others, gave promise, it must be admitted, is less conspicuous in some of his later productions; and he appears to have been seduced from the staid and somewhat severe simplicity which is one of the greatest charms of sculpture, by the fascination of highly-wrought execution and the elaboration of surface. In Flaxman exceptions will be found of a directly contrary character. In his works execution will be found a very secondary object compared with design, though in one of the finest compositions of which modern sculpture can boast, "The contest of Michael with Satan," Flaxman has shown that this deficiency is not to be attributed to want of knowledge or power. The works of these eminent sculptors are before the world; it is not therefore necessary to discuss them more particularly in this place. The influence of these second restorers of sculpture on the art of their day is acknowledged; and though distinct schools have arisen out of those which they may be said to have formed, the merit is justly due to them of having at least directed attention to that which is truly excellent.

Before concluding the history of sculpture with some few remarks upon its condition in England, it is due to the memory of a sculptor of distinguished merit to give him his just position in the list of those who have honourably and successfully exercised this art. Albert Thorwaldsen, a native of Iceland, but long resident in Italy, has left behind him several productions exhibiting a profound feeling for art: excellent in design, composition, and form. Like most modern sculptors, he drew largely from the ancients for his subjects; but he also illustrated others which were suggested by his own faith and feelings. His "Mercury" and his "Jason" are pre-eminent amongst the former; while in his majestic colossal statue of Christ, attended by the twelve apostles (now placed in niches in a church at Copenhagen), in his reliefs of "Charity," and other subjects from scripture teaching, he has, like our own Flaxman, shown that the modern artist need not necessarily be confined to heathen poetry and mythology for ample and exquisite materials for the exercise of his talents, al-

Sculpture.

Sculpture. though he may very properly adopt the principle of beauty of form which the Greek sculptors applied so admirably in their works.

The schools of sculpture of France, Germany, and Spain no doubt emanated from those established in Italy, and their earlier history is so closely connected with the revival of art in that country that it is not necessary to treat of them at any length. As the art progressed, the sculptors of each of these nations established their claims to distinction; and in France especially names of very high pretension are met with. Goujon was deservedly eminent even among the great artists of the sixteenth century; and the productions of Pilon, Puget, Girardon, Le Moine, Coustou, have secured for these artists a well-deserved reputation. The performances of the best of the French sculptors will bear comparison with those of any modern nation in knowledge of form, careful execution, and bold conception. The mode of treatment often, it must be admitted, partakes of the taste of particular periods, and, especially in the works of the seventeenth century, is marked by affectation and a somewhat theatrical air in the action and expression, which detract from the claims of the French to rank as a sound school of art; but in other respects the high qualities of the French sculptors admit of no dispute. It has always been the policy of the rulers of France to encourage the fine arts, and especially to foster native talent; and the interest thus shown has proved of the greatest advantage. It has, in the first place, given an honourable stimulus to their professors, and, in the next, the successful progress of the higher departments has acted most beneficially on the general character of design throughout all branches of industry. In the history of art in France there has been no illiberal exclusion of foreigners; but there always has been a patriotic feeling that native artists should be encouraged; and this consistent protection and interest in their progress may fairly be considered in no slight degree a cause of the high position the arts, in almost every department, have there attained.

The German school of sculpture, till of late years, was attached to a peculiar style which the national taste for simplicity and love of local association seem to have engrafted on the early Italian art which had penetrated into the country when the scholars of the Pisani travelled over Europe practising and teaching wherever they found employment. This has given a somewhat dry and quaint character to much of their sculpture produced before the sixteenth century, and it may indeed be found in works of a subsequent date. During the last fifty or sixty years great progress has been made in giving a higher quality of form to their productions in this art; and the execution of the works of the more eminent of the German sculptors is in no way inferior to that of any of their contemporaries. The influence of the modern artificial taste for classical imitations has extended to Germany, but it has acted less forcibly there than in Italy, France, or England; the national and domestic element, so strong in the German character, inducing their artists to exercise their art upon subjects which address the sympathies of the age.

Sculpture. In the sixteenth century sculpture was exercised extensively and with great success by native artists in Spain; and many of the churches possess works of a very high quality by Alonzo Cano, Hernandez, and their contemporaries. The close political connection that so long existed between Italy and Spain will account for the similarity of style in the art of the two countries, and many Italian sculptors of reputation visited Spain. Torregiano, as has been stated, proceeded thither from England, and died there after executing various works. A peculiar practice prevailed which gives a very remarkable character to the Spanish sculpture of the sixteenth century. The statues of religious subjects,—and in Spain the talents of the artists were almost exclusively exercised in the service of the church,—as the Saviour, the Virgin, saints, and similar personages, were carefully executed in sculpture, but afterwards they were as carefully painted, so as to imitate, with all possible truth, the appearance of nature. The effect of these works is said to be very startling, but very disagreeable; they appear almost to be living figures, or *tableaux vivans*, standing as models. This is a practice that cannot be admired or recommended by good taste. It in fact takes works out of the strict category of sculpture, without placing them in the condition of pictures. It is not the object of really fine sculpture or painting to make the spectator, who contemplates a picture, a group, or a statue, believe he is looking at real, living figures.¹

The short time, comparatively with other countries, during which sculpture has been practised in England, precludes it from taking a place in the early history of art with Italy, France, and Germany. The English sculptors exercised no influence on the style of the art; and it is not till the eighteenth century that any place can be claimed for our native artists. It may be observed, however, that although there is no account of the practice of sculpture, there is reason to believe that there were native artists in England at a very early date. No reliance can be placed on the traditional account, quoted by Flaxman, respecting the “great and terrible” statue of Cadwallo, who died 677; but two flat monumental effigies in the cloisters of Westminster Abbey, of two of its abbots, are of great historical interest. They are of the eleventh and beginning of the twelfth centuries. One is of Vitalis, who died in 1087; the other of Cuspinus, who died 1117. Whether two statues of Henry I. and his queen in Rochester cathedral were of that date, the middle of the twelfth century, cannot be determined; but there is evidence of the art having been exercised in England extensively within a hundred years of that time. It is worthy of remark, that Wells cathedral, which is copiously decorated with sculpture, was completed in the year 1242; and that Cimabue, one of the fathers of Italian art, was only born in 1240; and Giotto did not appear till 1276. The building of this church was therefore going on while Niccolò Pisano was exercising his art in Italy, and it was finished between thirty and forty years before one of the most interesting monuments of the kind in Italy, the Duomo of Orvieto, was commenced. The sculpture which decorates Wells cathedral is of course very rude in point of art; but

¹ The question of colouring sculpture is too large a subject to be entered upon here, where it is only referred to incidentally as a practice that has obtained at different periods in the history of the art. That the ancients employed colour in a variety of materials as well as in pigments, there is no doubt. Extreme decoration and love of finery is a characteristic of all early and barbarous nations, and it is found that the sculpture of remote antiquity was everywhere painted. As art in the times referred to was used almost exclusively for religious purposes, the mode of treatment became prescriptive; and therefore, even after a purer taste was established generally in design and form, as was the case in the age of Pericles, and when Phidias exercised his art, the established usage of richly decorating the statues of the gods was still adhered to in very many instances. The colour was put on thickly and uniformly over a *stucco* ground, and without tints. Vermilion and white were those usually employed for the naked parts. The eyes were often made of glass or stone. It is not possible to conceive that in their general practice the great sculptors of antiquity would consent to injure and conceal the perfection of surface they gave to their marble by thus coating and disfiguring it with thick opaque colour. It must also be borne in mind that colour was extensively used in architectural enrichment, and sculpture usually was so intimately associated with architecture that it partook of the decorative character, and was subject to its conditions. This gives, so far, a reasonable account for the practice of the ancients, but it affords no excuse for the affectation of its modern re-introduction in isolated and gallery statues. (Kügler, *Polychromie*; Westmacott, *On Colouring Statues*, 1859; Hittorf; Quatremère de Quincy, *Le Jupiter Olympien*, &c.)

Sculpture. It is of great interest, from the character of the designs, and from the date of its execution. It illustrates various subjects of Scripture-history and acts in the life of our Saviour; besides recording, in statues of heroic size, the memory of saints, kings, queens, and others, who were probably patrons and benefactors of the church. Another circumstance of interest is, that it seems to be the earliest example in this country of such sculptural enrichment exhibiting a connected series of Scripture illustrations; but its importance may be still greater if, as has been conjectured, it is the first specimen of the kind known to exist in Western Europe. Its origin, then, becomes a question of some importance. It is not improbable that some of the earliest Italian practitioners may, in their wanderings, have penetrated as far as England; but the style of the sculpture certainly does not resemble that of the Italian artists who undoubtedly were employed on the tombs of Edward the Confessor and of Henry III.; and, therefore, it is not so easily associated with the art derived from that source. Flaxman, admitting this, was disposed to think it was derived from the East, conceiving that, as it was not Italian, it might have been founded on examples seen by the Crusaders; a speculation which has little probability to recommend it. That the Crusaders influenced the civilization of Europe must be conceded, inasmuch as many of the ingenious eastern arts became known, and were introduced by those who returned from those wars; but it scarcely can be likely that any light could be thrown on sculpture by the practice of the eastern nations. No writer seems to have allowed himself to think it possible that the English could have been capable, at any period of their history, of producing such art as was required for the decoration of their sacred and other edifices, even of the rude and primitive kind under consideration; and therefore all have taxed their ingenuity and invention to give the honour of it, such as it is, to any rather than their own countrymen. The preponderance of the foreign element in the courts of the sovereigns of England, and the little knowledge of, or feeling for, art in the higher classes, have always tended to depress or ignore the attempts of native artists to do at home that which the artists of Italy, France, and Germany effected for the credit of their respective countries; and on all occasions, till a comparatively late period, foreign painters and sculptors were preferred and employed. Want of opportunity and want of practice, all-sufficient causes in themselves of inferiority, were assumed, too often by those but little competent to judge, to be proofs of national incapacity; and till Christopher Wren vindicated the honour of his country in architecture it seemed never to have occurred that an Englishman could make himself worthy to take a position as a real artist. Without entering into the question of the greater or less degree of sensibility in the northern nations to the various forms of beauty, whether in the imitative arts or in music, there can be no doubt that this habit of slight and depreciation by those from whom, from their influence and position, encouragement might rather have been expected, suppressed the growth of art among the English, and paralysed the efforts of the few who might have any desire or ambition to practise it. It must, however, at the same time be admitted, that with the disadvantages that doubtless accrued to the establishment and progress of native art in England by the constant immigration and employment of foreigners, some advantages have also to be acknowledged. The inducement held out by the liberal remuneration to be procured in England by every kind of talent occasionally brought among us artists of a superior class, from whom much could be learned in matters of technical detail, in which our own ill-educated practitioners were greatly deficient; and there can be no doubt that this led to considerable improvement in our own schools. In the seventeenth and eighteenth centuries, however, art in England, with

very trifling exceptions, was in the same low state with Sculpture. respect to taste as it was on the Continent; and the sculptors (foreigners, of course) who were then practising here, —Scheemacher, Rysbrach, and Roubiliac—have left evidence of the debased condition of the art, although, as has before been observed, there are among the works of the last-named artist many productions of great merit.

It may not be out of place to mention here that England is very rich in its series of ecclesiastical and monumental sculpture, from the earliest introduction of that class of art in this country. Reference has already been made to the effigies in low relief of two abbots of Westminster, in the eleventh and twelfth centuries, and to the statues which decorate Wells cathedral. At first all sculpture to commemorate individuals was confined to the ecclesiastics, the clergy having the exclusive control over these works. The earliest monumental effigy of a king is that of John in Worcester cathedral, the date 1216. The next of royal personages are those in bronze, in Westminster Abbey, of Henry III. (1272), and of Eleanor the queen of Edward I. (1290). From this time there is a continued succession of such works, which are not only highly valuable from their historical importance, but for the illustration they afford of the changes in the style of monumental design. Some of those of the end of the fourteenth and the fifteenth centuries are particularly rich in design, and deserve attention for many valuable qualities of art. It will be observed that, from its commencement till about the end of the sixteenth century, monumental sculpture exhibits the influence of the religious feeling of the earlier ages. It was of course modified in its forms and mode of representation, as may be seen in numerous examples of easy reference that abound in our cathedrals and older churches, but everywhere the prevailing sentiment was religious. Figures, whether they are lying recumbent on their tombs or kneeling, a posture not so often met with in the principal subject in early monumental sculpture, are usually represented praying; or if not literally occupied in the act of prayer, they generally have accessories or accompaniments referring to religious exercises, or are attended by ministering angels, either supporting the cushion at the head or grouped at the feet of the person represented. Of course there are exceptions to this rule, as in the effigies of the knights in the Temple church, and others that might be mentioned; but generally the sentiment described was the prevailing one in this class of works. In the sixteenth century a departure from this characteristic of church sculpture is observable, and in a few years all reference to the religious character in such works is lost sight of. The taste exhibited in monumental design of the date of Elizabeth and James I. is exceedingly bad, but after that time this class of art still further deteriorated, and the monuments produced in the latter part of the seventeenth century are for the most part entirely wanting in the associations which seem to be so essential in works of this kind.

It has been asserted—and the assertion has, for want of being properly canvassed, been too readily admitted by some writers—that the decline of art in England, and especially the change in the sentiment of monumental design, was owing to the Reformation, in the sixteenth century. This opinion is quite unfounded. In the first place England had no distinct school of art; all, or almost all, that was produced was by foreigners. In the next, if the deterioration of art is to be attributed to the change in the religious convictions of the nation, the proof of it should be found only among the people of the Reformed Church. But so far from this being the case, examples of monuments in places of worship, deviating much more strikingly than our sculpture from all religious and Christian character of design, abound all over the Continent. In Rome, especially in St Peter's; where, according to the view of the opponents

Sculpture. of the Reformation, the utmost propriety and purity of design might be expected, nothing can be worse than the taste and feeling exhibited in most of the monuments of the time referred to. Some of these works are not only utterly inappropriate, but are of a most objectionable character. Indeed, in this particular, it would not be difficult to show that, though the later Puritan feeling carried the anti-art prejudice to an excess which is to be deplored, the Reformation, instead of assisting in debasing art, was a powerful cause of purifying it. It is a subject of just and honourable pride that such objectionable and even scandalous subjects as occasionally occur in England in screens and on choir-stalls of the mediæval time, and which, being in sacred places, were of course executed under the sanction of the clergy, are never met with in the later decoration of the reformed religion. This subject is here only briefly touched upon with reference to the sentiment of a particular class of art; and to vindicate the Reformation from the unjust charge of having corrupted taste.

There was a slight re-action in favour of art in the reign of Charles I. It was occasioned chiefly by the introduction of some works of art from the Continent; and the interest in the subject exhibited by the king himself and his desire to acquire objects of the kind gave an impulse to the taste for art in his court. The political disturbances that soon began to disturb the kingdom were, however, fatal to the development of this feeling; and though there was considerable patronage and encouragement given to the sister arts, sculpture rapidly declined. After the death of Charles I. the collections he had made were dispersed, many of the finest productions in painting being sold and carried out of the country. The original cartoons of Raffaele and those of Andrea Mantegna, both now preserved at Hampton Court, would have shared this fate, and would have been lost to us but for the interference of Cromwell. By his command they were purchased for the nation.¹

Three sculptors of some eminence may be noticed here who were practising with success in England. Stone, who died in 1647, is the author, among other works, of a large monument in memory of a member of the Newcastle family, in Westminster Abbey, and which Flaxman, in his review of English sculpture, thinks worthy of commendation. Caius Gabriel Cibber, born in 1630, is known as the sculptor of the two stone statues of "Madness" and "Melancholy" at Bethlehem Hospital. They are remarkable works for expression, and for bold and vigorous design and execution. Grindley Gibbon was the sculptor of the bronze statue of James II. in the court-yard of the banquetting-house at Whitehall, a work of considerable merit, though the action is rather theatrical. The costume is that of a Roman general. This artist deserves particular mention as one of the most distinguished carvers in wood. He was much employed by Charles II. at Windsor Castle and Hampton Court, where his works may still be seen. He also executed the wood carvings in the screen of St Paul's Cathedral, as well as other elaborate performances of the kind at the country seats of many of the nobility. His imitation of birds, dead game, foliage, fruit, and such objects, deserve the highest praise. He died in 1721.

Nothing could be lower than the state of sculpture in England during the reigns of the two first Georges. In that of George III. a new era commenced. The position and importance of art as a pursuit honourable to a civilized nation were admitted, and the first national acknowledgment of its existence in England was made. It is not yet a hundred years since this was effected, but the result of this recognition has been of a kind amply to satisfy those who hoped well for the credit of English talent. Artists

have in this short time appeared who will bear comparison with their contemporaries all over the world. To mention but a few names: in architecture, Wren and Chambers; in painting, Reynolds, Gainsborough, Wilkie, and Turner; in engraving, Sharpe and Woollet (and there are many others who might easily be added in all branches of the arts), have triumphantly disposed of the charge of national incompetency. Of living artists, many of whom have justly acquired a widely-extended reputation, it would be invidious here to speak. In sculpture, England has within the last few years possessed very eminent names; and as some of these have exercised considerable influence, it may be desirable, in concluding this part of the history of the art, to point out the leading peculiarities that have marked their practice.

The chief sculptors who arose after the disappearance of the Rysbrach and Roubiliac schools, and who began to exercise their art with some independent feeling, were Banks, Bacon, Nollekens, Flaxman, Westmacott, and Chantrey. The merit of Banks may be judged of by his large group in the façade of the gallery of the British Institution in Pall Mall, representing Shakespeare between Poetry and Painting; by his elegant and expressive composition in marble in the National Gallery, of "Thetis rising from the Sea to console Achilles;" his fine statue in marble in the Royal Academy of "A Falling Giant," and other works. Nollekens produced many works showing a close observation of nature and accomplishment in the executive part of his art. In busts especially his practice was very great, and he also produced some statues of considerable merit. His drapery was, however, poor in design, and showed the influence of the weaker parts of the preceding schools.

Flaxman has made an European reputation of which his country may feel justly proud. As a designer, his fame is established by his compositions from Homer, Æschylus, and Dante, as well as by other works. Among his productions in sculpture may be especially mentioned the group of "Michael overcoming Satan;" a performance that places its author in the very highest rank of sculptors. His composition in rilievo of "Mercury conveying Pandora to Earth," those from the Lord's Prayer, his elaborate and classical "Shield of Achilles," after Homer, cast in gold, and numerous works illustrating passages of Scripture, introduced in monumental designs, attest the fertility of his invention and the true genius that characterised his conceptions. Flaxman's style was founded on the beautiful ancient examples, especially in the designs on Greek fictile vases, modified by his sympathetic appreciation of the simplicity and sentiment of the early Christian art of the Pisani and their followers. With Flaxman execution was subservient to invention, and it must be admitted that many of his most beautiful conceptions suffer from their inadequate execution.

Westmacott derived his earlier impressions from the ancient statues; and the influence of antique art appears in the generality of his designs. Some very original conceptions are, however, found in this artist's works. Among these, the large alto-rilievo of the "Dream of Horace," at Petworth, the illustrations of the Progress of Civilization, the Invention and Progress of Navigation, and similar subjects deserve attention. Among his best known ideal or sentimental statues, not of the antique school, may be mentioned the well-known group of the "Distressed Mother," and a group of the "Virgin and Child." These have great expression, and are also examples of a deep knowledge of the requirements and true principles of the art. His portrait-statues in bronze and marble are numerous, and many of his public monuments, exhibiting great fancy and invention, may be seen in the churches and public squares in different parts of England.

¹ It is curious to know that the cartoons of Andrea Mantegna were valued at L.2000, while those of Raffaele, which had been purchased for Charles I. by Rubens, were estimated at only L.300.

Sculpture. Chantrey had no academical education in the art in which he became so eminent; a circumstance which accounts for many of the excellences and defects of his practice. His sound common-sense enabled him to perceive the falsehood of a school of modern art which was always repeating ancient designs and forms, and he therefore took nature, as he viewed her, for his example. In his portrait-statues in their modern costume, and in his busts he identified himself with his own age and people. In his busts of men he was without a rival; for although they are wanting in what the learned in art understand by ideality, they exhibit a truthfulness in their individuality and character that justly place them among the best works of their class. In many of his portrait-statues the same power of seizing the salient points of character are seen. But few ideal or "gallery" works by Chantrey exist. Indeed, his strength consisted in his ability to deal with the real or natural; and, not having any sympathy with merely classical art, he judiciously confined himself, with few exceptions, to the treatment of subjects out of the pale of poetical fancy or invention.

The influences that affected the leading sculptors of the English school may still be variously seen in the productions of living artists. While some have preferred the ancient Greek examples, both for subject and the mode of treatment, others have sought in commoner modern sources both the subjects for illustration and the forms in which they are to be presented. This country may now boast of a considerable amount of executive talent in sculpture; but the ultimate judgment as to the merit of the artist must be left to the just award of time. A too strict subserviency to ancient example may retard the progress of a true, original school, and may tend to establish cold, passionless, artificial, or academical art, while an injudicious and too close imitation of the merely natural may, in like manner, lead to a low standard of subject and form, and thus debase a high and fine art to the condition of vulgar, commonplace image-making. It is from the union of the expressive, which can be appreciated by modern feelings and sentiment, with the highest forms of beauty, of which the true elements are found in the principles pervading Greek sculpture, that the most happy success will result.

The processes of sculpture are now so generally known that it scarcely seems necessary to describe them; but as a history of the art would scarcely be complete without some little explanation of the mechanical and technical conduct of a work, a few general indications of the sculptor's mode of proceeding are here added.

The artist having invented or conceived his subject, usually begins by making a small sketch of it in some plastic or obedient substance, as clay or wax. He can change and alter this at his pleasure till he is satisfied with the composition, and the arrangement of the light and shadow. He then proceeds to copy it in his statue or group of its intended size. Before commencing the larger model it is necessary to form a sort of skeleton or frame-work of iron and wood, with joints made of wire to support the great mass of clay. This iron frame is firmly fixed upon a turning bench, or banker, so that the model may be constantly moved without difficulty. As the clay is likely to shrink as it gets dry, it is necessary occasionally to wet it by sprinkling water over it with a brush, or from a large syringe, and by laying damp cloths upon it. This is the process for preparing a model in the "round." In modelling rilievo of either kind, a plane or ground is prepared upon which the design is or should be carefully drawn. The clay is then laid in small quantities upon this, the outline being bounded by the drawing; and the bulk or projection is regulated by the degree of relief the sculptor requires. If the final work is to be in baked clay (*terra-*

cotta) there must be no iron or wooden nucleus, and the model is prepared for drying without such support. When perfectly dry, the model is placed in an oven and slowly baked, by which it acquires the peculiar brownish-red colour seen in these works. If the final work is to be in marble, or bronze, or plaster, the next process after finishing the model is to mould it. This is done by covering it with a mixture of plaster of Paris with water, which quickly sets, forming a hard and thick coating over the whole. The clay is then carefully picked out, and an exact matrix or form remains. This is washed clean, and the interior is brushed over with any greasy substance, usually a composition of soap and oil, to prevent the fresh plaster with which it is to be filled adhering too firmly to it. The fresh plaster is mixed to about the consistency of cream, and then poured gently into the mould till all the surface is filled or covered. When this is set the old plaster mould is carefully knocked away with chisels, and the true cast appears beneath, giving an entire fac-simile of the model. Some skill is required in making moulds, in order to provide for projecting parts and undercuttings; practice alone can give this. The above general instructions explain the ordinary process. In metal casting or founding attention must be paid to the strengthening of the parts to bear the weight of the metal; but the principle described in plaster-moulding applies also to the preparation for metal-casting. The mixture of metal to form bronze, the heating of the furnace, burning, chasing, and other processes of founding, cannot be fully described in this place, as they belong to a distinct practice.

If the model is to be copied in marble or stone, the first step is to procure a block of the required size. Two stones, called *scale-stones*, are then prepared, upon one of which the model or plaster cast is placed, and upon the other the rough block of marble. The fronts of these stones have figured marks or "scales" exactly corresponding. An instrument, capable of being moved by socket-joints and moveable arms, is then applied to the scale-stone of the model, and a projecting point or "needle" is made to touch a particular part of the model itself. This is carefully removed to the scale-stone of the rough block, and the marble is cut away till the "needle" reaches so far into the block as to correspond with the "point" taken on the model. A pencil-mark is then made to show that the point is fixed. This process is repeated all over the model and the block till a rough copy or shape of the model is entirely made. These "pointing" machines are not always precisely alike, but the principle upon which they act is exactly similar in all. The statue being thus rudely shaped out, the block is placed in the hands of a superior workman, called a carver, who copies the more minute portions of the work by means of chisels, rasps, and files; the pencil-marks showing him the precise situation of the parts and the limits beyond which he is not to penetrate into the marble. When the carver has carried the work as far as the sculptor desires, he proceeds himself to give it the finishing touches, improving the details of form and expression, producing varieties of texture, and harmonizing the whole.

The rich quality of surface that appears more or less in works in marble is produced by rubbing with fine sand or pumice-stone and other substances, and the ancients appear to have completed this part of their work by a process called by Pliny "*circumlatio*," which may probably mean not only rubbing or polishing, but applying some composition, such as hot wax, to give a rich colour to the surface. Many of the ancient statues certainly exhibit the appearance of some foreign substance having slightly penetrated the surface of the work to about one-eighth of an inch, and its colour is of a warmer tint than the marble below it. This process is quite distinct from *polychromy*, or what is usually understood by colouring sculpture. (R. W.—T.)

Scuppers
||
Scylla.

SCUPPERS are metal pipes inserted in openings bored from the deck through the sides of a ship, to carry the water off from the deck to the sea.

SCURVY, a constitutional disease in which the quality of the blood has been much impaired, owing mainly to the absence for a great length of time of fresh vegetable diet and other articles, containing the salt of potash. It was formerly very prevalent among our seamen, but for many years, except in rare cases of neglect, it has not been heard of. The supply of a portion of lime or lemon-juice daily, effectually checks any tendency to scurvy.

SCUTARI, or **SKUTARI** (anc. *Chrysopolis*), the largest of the suburbs of Constantinople, forming a town of itself, on the opposite side of the Bosphorus, on seven low hills. The modern name is derived from the Persian *Ushkudar*, a courier, on account of this being the post-station for couriers to and from the east. The town contains several mosques founded by sultans or sultanas, a large palace, barracks, several imarets or kitchens for the poor, baths, and convents. Among the last, the most remarkable is that of the howling dervishes, which is visited by many Europeans on account of the singular and fanatical rites performed. The cemetery of Scutari is much larger and more beautiful than any in the capital, on account of the sacredness supposed to belong to Asiatic soil. The town contains silk-mills and cotton factories; and has a considerable trade. In the vicinity there are many beautiful villas and country-houses. During the Russian war of 1854-6, the hospital of Scutari was used by the allied armies. Pop. estimated at 60,000.

SCUTARI (Albanian *Skodra*), a town of European Turkey, Albania, capital of a pashalic in the eyalet of Rumili, at the southern extremity of the Lake of Scutari, from which the Boyana here issues, 45 miles S.E. of Cattaro. It is walled and defended by two castles; contains a bazaar, numerous mosques, Greek and Roman Catholic churches. Ship-building, woollen and cotton weaving, and the manufacture of fire-arms, are carried on here. Scutari is the principal place of trade in Bosnia and Albania, as three important routes cross each other here—that from Constantinople to the Adriatic; that from Belgrade to the Mediterranean; and that from Dalmatia to Albania. Pop. 24,000.

SCUTTLES, in a ship, holes in the decks of a ship, either for air or as passages to the store-rooms; also openings in a ship's side for the admission of air. If, in order to sink a ship, a hole be cut in her bottom, she is said, in nautical language, to be scuttled.

SCYLLA, or **SEIGLIO**, a town of Naples, in the province of Calabria Ultra, on a promontory of the same name, at the Strait of Messina, 11 miles N.N.E. of Reggio. At the outmost point of the land stands the castle on a steep cliff; behind this the town is built on a neck of land, picturesquely rising in zig-zag terraces from the sand on either side. It contains numerous fountains, and some very handsome buildings; has important silk manufactories, a considerable trade, and an extensive fishery. Scylla suffered very much from an earthquake in 1783. Here is the once dreaded rock Scylla, of classical fame; but it is now passed without danger or fear by the navigator. Pop. 4560.

SCYLLA and **CHARYBDIS**, the names of two rocks in the Strait of Messina, fancifully described as sea-monsters by Homer, and after him by many of the best poets both in ancient and modern times. These descriptions are plainly intended to typify some objects of imminent danger and terror; and though it would be absurd to seek too minutely for a local habitation of such creations of the fancy, it is not improbable that the idea was originally derived from the exaggerated rumours about rocks and eddies that would be brought home by such adventurous seamen as had the courage, in their frail uncovered boats, to attempt

Scyros

Scythia.

the passage. Scylla is represented in different forms, with six heads, or with three, or with a fish's tail encircled by ever-howling dogs. She dragged vessels on the fatal rocks; while Charybdis, on the other side, engulphed them in the water, which she alternately sucked in and ejected from her capacious jaws. In modern language, Scylla and Charybdis have passed into a proverbial metaphor, expressing the difficulty of avoiding opposite extremes or dangers.

SCYROS, now **SKYROS**, or **SKYRO**, an island belonging to Greece, one of the group called the Sporades, in the Ægean Sea, 25 miles E. of Eubœa. Length about 17 miles; breadth from 2 to 7; area about 60 square miles. It consists of two parts united by a narrow isthmus in the centre, where there is a tract of low level ground. The northern and southern extremities are mountainous, especially the latter, which is the loftier, abounding in bare cliffs and deep ravines, clothed only with wild forests of oaks, pines, and beeches. In the northern portion the hills are less elevated; and these, as well as the valleys and plains, are covered with rich corn-fields, vineyards, and pastures. Corn, wine, and madder are the most valuable productions of the island; oranges and other fruits are grown; and goats of a good breed are reared. At the town of St George, on the east coast, which contains nearly all the inhabitants, some remains of the ancient capital have been found. On the west side the bay of Kalamitza forms a good harbour. Scyros is more than once mentioned in the ancient legends of Greece. It was here that Theseus, after retiring from Athens, was treacherously murdered by Lycomedes; and Achilles, according to one tradition, was sent hither by Peleus to avenge his death. In 476 B.C., the Athenians were directed by an oracle to bring home the bones of their tutelary hero; and accordingly no long time elapsed before Cimon conquered the island, expelled the former Dolopian inhabitants, colonized it with Athenians, and brought the bones of Theseus to the Theseium at Athens. The island long remained subject to the Athenians; afterwards it passed into the hands of the Macedonians, and still later into those of the Romans. Pop. 2630.

SCYTHE. See **AGRICULTURE**.

SCYTHIA, a name given by the ancients to a large tract of country, inhabited by a race of people whom they called Scythæ, but who called themselves Scoloti. The position and extent of this country, according to different writers, differ very considerably; and especially Herodotus and Ptolemy, who give the most distinct information on the subject, are completely at variance, the former placing it entirely in Europe, and the latter almost entirely in Asia. According to Herodotus, who does not recognise the country called Sarmatia by later writers, the Scythians occupied a portion of it, extending from the Ister (Danube) to the Palus Mæotis (Sea of Azoff), and the Tanais (Don); and from the Euxine northwards to the country of the Melanchlæni. Eastward from Scythia lay the country of the Sauromatae, between the Tanais, the Rha (Volga), and Caucasus; while the region between the Borysthenes (Dnieper) and the Tanais was at one time occupied by the Cimmerians, who were expelled by the Scythians. Scythia, therefore, in the time of Herodotus, comprehended Moldavia and the southern portions of European Russia. The Scythians themselves, according to the historian, were a branch of the Sacae, an Asiatic people living to the east of the Caspian, and had been driven out from their original country by the Massagetae. Only two important events in Scythian history are mentioned by Herodotus; the one is the invasion of Media by the Scythians, and the other that of Scythia by Darius. In 624 B.C., the Scythians entered Media, defeated Cyaxares, the reigning monarch, and occupied the land for twenty-eight years before they were expelled. It was at least ostensibly in revenge for this

Scythia. incursion that Darius Hystaspis determined to invade Scythia about 513 B.C. He formed a bridge across the Danube; and crossing that river, obtained some advantages over the Scythians. But he was unable to effect any real conquest of these nomad tribes, and narrowly escaped having his retreat cut off by the destruction of the bridge. In later times we do not hear much of the Scythians in history. Instead of them the Sarmatians appear as the occupants of these regions. Whether this is to be accounted for by supposing that the Sauromatae of Herodotus encroached upon the Scythian territory and supplanted its former inhabitants, or we are to believe that the change was only in the name by which these nomad tribes were known to the Greeks and Romans, is a doubtful point; but there can be no question of the fact, that in the time of Ptolemy the term Scythia was applied exclusively to those eastern regions, which even, according to Herodotus, formed the original home of the Scythians. Scythia was, according to this view, bounded on the W. by the Rha, which separated it from Sarmatia; S. by the Jaxartes (Sir Daria), which separated it from Sogdiana, and by the Emodi Montes (Hindoo Coosh and Himalayas), which separated it from

India. On the N. and E. there was no definite boundary; in these directions lay the lands of the Seres and the Sinae. Scythia was divided into two parts, inside and outside the Imaus, a name applied somewhat vaguely to the mountains of Central Asia; but which probably indicates in this connection the ranges now known as Bolor and Thian Shan. Scythia intra Imaum would thus comprehend the Kirghize steppes; and Scythia extra Imaum Tibet and Little Bucharina. The term Scythia, as used by Ptolemy, thus corresponds very much to the similarly indefinite terms Tartary and Turkestan, which we apply to nearly the same regions, dividing it in a similar way into the western or Independent, and the eastern or Chinese portion. The Scythians of the ancients are also probably to be identified with the Turkish races; and it will no more surprise us to find the former in ancient times occupying the position assigned them by Herodotus, than to find the latter at the present day occupying European Turkey. The physical characteristics, manners, and language of the Scythians, so far as they can be ascertained, confirm this opinion, though some eminent authorities have arrived at different conclusions.
